# Get Started with the OcientAIQ Unified Data Platform

Welcome to Ocient documentation. Find setup guides, SQL references, machine learning, geospatial features, integrations, and operations for the platform.

The OcientAIQ™ Unified Data Platform is a petabyte-scale data platform that brings AI, analytics, and high-performance query execution directly to enterprise data. Rather than requiring you to move, copy, or sample large data sets across fragmented systems, the platform unifies data ingest, query optimization, security, and governance in a single platform. Agents, applications, and analysts connect to the platform to work with governed enterprise data in place.

The platform supports both structured and semi-structured data, giving AI and analytical workloads access to richer context without additional data pipelines. The platform continuously ingests high-volume data so that it is available for queries and AI-driven workflows as it arrives. Built-in access controls, auditability, and compliance features protect data across every interaction — whether the consumer is a human analyst, a BI tool, or an AI agent.

You can deploy the platform in the environment that fits your operational, security, and data-sovereignty requirements. The following sections introduce the core concepts that define how data is stored, organized, and executed within the OcientAIQ Unified Data Platform.

**Key Concepts**

Core Ocient® concepts and terms needed for a quick start

# Key Concepts

Learn the core concepts behind the Ocient System, including architecture, scalability, and analytics designed for large complex data sets.

The OcientAIQ™ Unified Data Platform is a real-time OLAP datastore designed for running analytics against large time series data sets. The Ocient® System operates in compliance with the ANSI standard for SQL.

The Ocient System includes:

- **Ultra-fast query speeds** for analytics on hyperscale data sets.
- **Scalability** for cost and performance on a system built with commodity hardware.
- **Flexible deployment** for running on premises, in the cloud, or as an Ocient-managed service.
- **Robust functionality** for DDL, geospatial (OcientGeo™), and machine learning (OcientML™).
- **Data movement** at scale for ETL and ELT ingestion and operations.

## The Ocient System

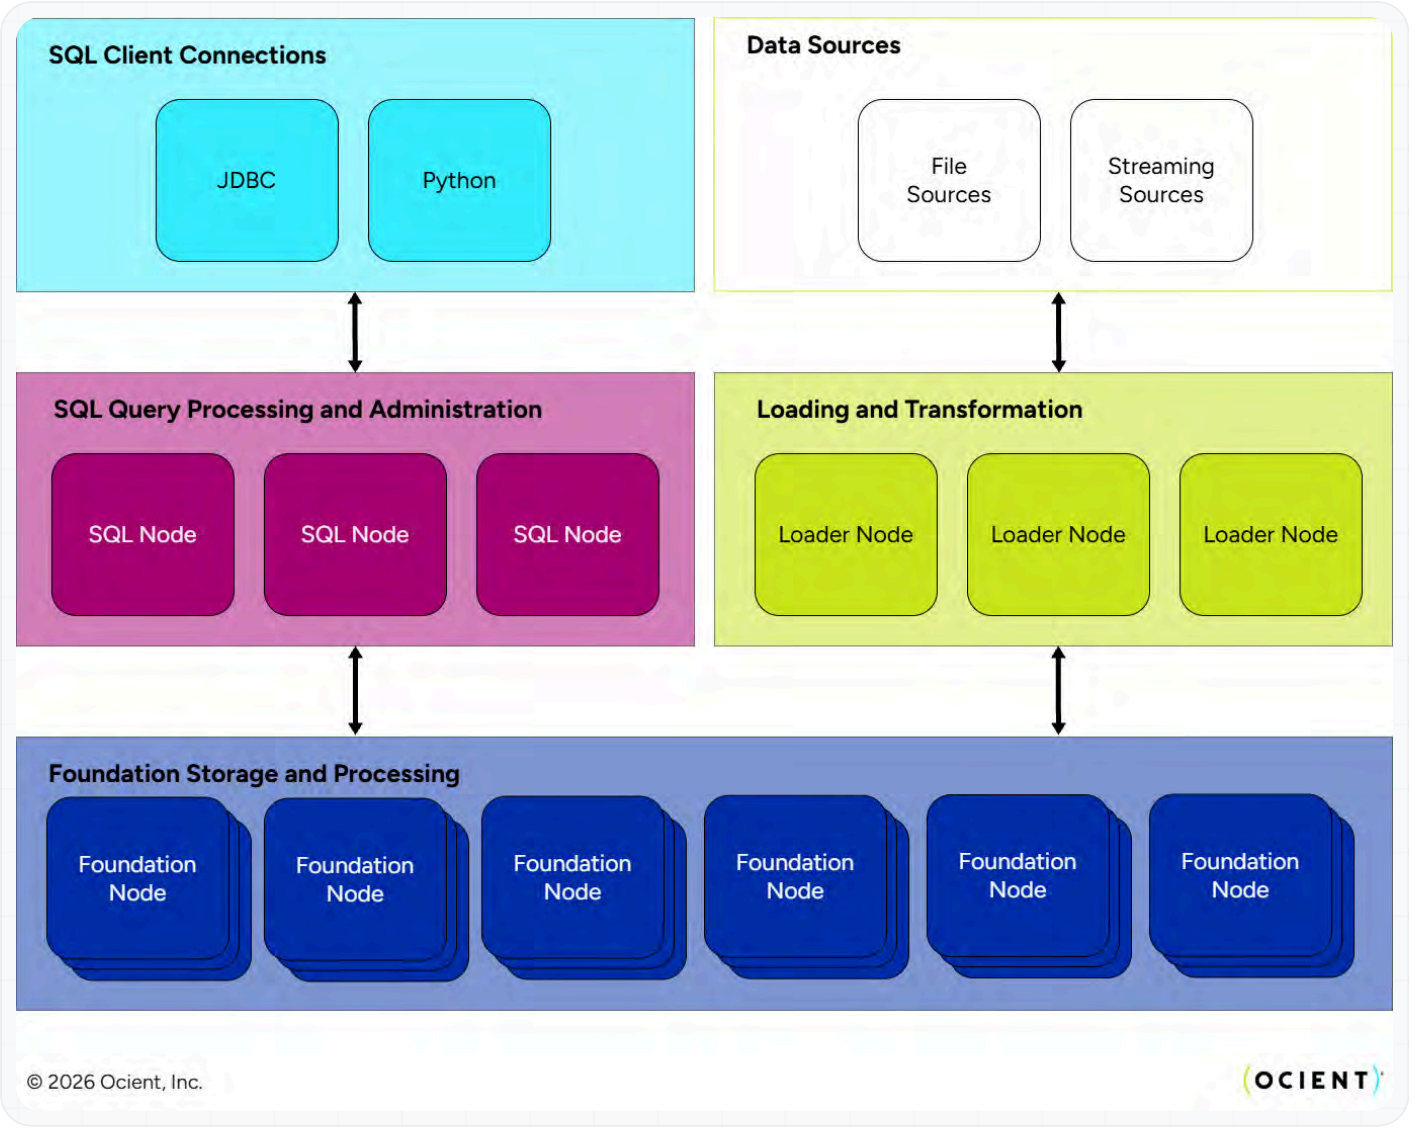
The Ocient System is based on Compute Adjacent Storage Architecture® (CASA), which collocates NVMe drive storage with the system compute resources to optimize performance. This design keeps records near and accessible for computation without a separate storage layer, which avoids many common bottlenecks for database engines, such as limits on network capacity or processing throughput. The design achieves superior query performance when it operates on trillions of rows of data.

To learn more about the design principles behind the Ocient System, see **Ocient Architecture**.

## Deployment

Ocient is designed for flexible deployment for unique use scenarios that include:

© 2026 Ocient, Inc
Ocient Proprietary and Confidential



- OcientCloud® — A cloud deployment managed by Ocient Support. This option uses performance-tested hardware and network infrastructure.
- Public Cloud — Installation on third-party cloud providers, including Amazon® Web Services℠ (AWS℠) and Google® Cloud™.
- On premises — A self-managed option for hosting Ocient in your own data center.

## System Nodes

Ocient is a distributed system consisting of interconnected nodes within clusters, which together form the data warehouse. The Ocient System designates nodes for these system roles:

- **SQL Nodes** — Parse incoming SQL statements and administer commands throughout the system. These nodes serve as the interface for system and database administration. SQL Nodes also host the **Ocient Management UI**, a web-based interface for monitoring and managing the system.
- **Loader Nodes** — Manage ETL ingestion from batch or streaming sources and index data for optimized performance.
- **Foundation Nodes** — Store data and perform the bulk of query processing. Foundation Nodes perform as much query processing as possible on their stored data before interacting with other nodes.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Understanding nodes and their roles in an Ocient System is most useful for system setup, administration, and maintenance. For details about nodes, see **Ocient Architecture**. However, the Ocient System makes it easy to load and query data without knowing these details.

## Data Types

The OcientAIQ Unified Data Platform, the functions, and the indexes use only native SQL data types to optimize storage and performance. Supported data types include common SQL scalar types and complex types such as IP, arrays, tuples, and geospatial. For details about supported data types, see **Understanding Data Types**.

## Loading

The Ocient System can load data for an end-to-end flow from file or streaming sources, including common sources such as:

- Apache® Kafka®
- AWS S3
- Apache® Hadoop® Distributed File System (HDFS)

For all the source and format options, Ocient uses pipelines to control ingestion. You can control pipelines using DDL commands, API on Loader Nodes, or a command-line interface. You can transform data during loading using SQL functions.

Loading ingestion throughput can scale as needed based on the Ocient architecture.

For details, see **Load Data**.

# Query Processing

The design of the Ocient architecture minimizes the amount of on-disk data that must be read and processed to execute a query. To do this, the system compiles a custom I/O pipeline for each data segment relevant to a query. These custom pipelines leverage any keys or indexes to improve throughput.

To learn more about query processing, see **Query Performance Optimizations**.

## Ocient Indexing

An Ocient datastore can use multiple layers of indexing to facilitate query performance. Using these indexes is pivotal to optimizing query performance for large data sets.

You can apply indexes using basic DDL statements that do not require deep knowledge of the internal system or data set. You also have some ability to customize indexes for their specific use cases.

Indexes are divided into two main categories.

1. **Segment Keys**

© 2026 Ocient, Inc

These indexes require no additional storage and usually should be deployed on every table. Segment keys operate by accessing data from the partitioned data segments to quickly filter rows without I/O processing.

Segment keys include:

- **Time Key** — A segment key that partitions data based on a time-series data column.
- **Clustering Key** — A series of columns that are frequently queried together. The system subdivides these segments on disk for faster reference.

For more information on segment keys, see **TimeKeys and Clustering Keys**.

2 **Secondary Indexes**

When deployed precisely, Ocient secondary indexes can dramatically reduce the time for queries to run on large data sets.

Ocient supports secondary indexes for these data categories:

- **Numeric**
- **String**
- **Partial string**
- **Geospatial**

For more information, see **Secondary Indexes**.

# Transactions

The Ocient System supports transactions that group one or more SQL statements into a single unit of work. The database either commits all changes or rolls them back as a whole. Use transactions to ensure data consistency across loading and querying operations when a set of related changes must succeed or fail together.

For details, see **Transactions**.

© 2026 Ocient, Inc

# Connecting to Ocient

Ocient provides SQL access to its database using industry-standard interfaces:

- JDBC
- pyocient, a Python®-based driver for Ocient.
- HTTP Query API, a REST-based interface for executing SQL statements.
- Apache® Spark™ Connector, a DataSourceV2 implementation for reading from and writing to Ocient tables using Apache Spark.

End users can query and analyze data in Ocient without understanding the organization, nodes, networking, or other parts of the system architecture.

For more information, see **Connect to Ocient**. For details about the connection drivers, see **Connection Driver Reference**.

## Integrations

Ocient supports integration with various third-party tools for database administration, business intelligence, and system monitoring.

For details about supported third-party tools, see **Ocient Integrations**.

# Management UI

The Ocient Management UI is a web-based interface hosted on SQL Nodes that provides at-a-glance visibility into system health, query activity, data ingestion, storage utilization, and node status. The Management UI also includes an interactive SQL Console to execute queries directly in the browser and a Pipeline Builder to create data pipelines without writing DDL statements.

For details about UI features, see **Ocient Management UI Features**. For connection and configuration details, see **Ocient Management UI Configuration**.

# AI Agents and the Ocient MCP Server

The Model Context Protocol (MCP) is an open standard that gives AI agents a consistent way to discover and invoke tools. The Ocient MCP Server implements this standard for the Ocient System, so AI agents and AI-powered code editors can explore schemas, execute SQL statements, and invoke custom analytical tools through natural language conversation instead of a SQL client.

The database stores the definitions of all MCP tools, both the system tools that ship with the Ocient System and the user-defined tools that you create with the `CREATE MCP TOOL` SQL statement, and the server discovers them dynamically at runtime. Because standard database privileges govern every tool, agent access follows the same access controls as any other database user.

For details, see **Ocient MCP Server**. To create your own tools, see **Model Context Protocol Tools**.

## Machine Learning

The Ocient System includes OcientML functionality for training and executing machine learning models directly within SQL. OcientML builds on native linear algebra support, including first-class matrix data types and operations such as matrix arithmetic, inversion, and eigenvalue decomposition.

You can create models using the `CREATE MLMODEL` statement and execute them as scalar functions in queries. Ocient supports a broad suite of models spanning regression, classification, clustering, dimensionality reduction, ensemble methods, and neural networks to address a wide range of analytical use cases.

For details, see **Machine Learning in Ocient**.

## Resilience to Hardware Failure

The Ocient System uses erasure coding to organize and compute parity blocks so the system is fault-tolerant and can rebuild missing data. This failsafe does not require redundant copies of data, meaning that storage requirements are minimal.

## Security

As a unified platform, Ocient helps keep data secure by consolidating security capabilities and reactions in one place with a suite of auditing and monitoring tools. Ocient supports these security standards:

- **Data Encryption:** Optional through TLS/SSL protocols.
- **Security Compliance:** Audited and certified SOC 2 Type 2.
- **Monitoring**: Log-level monitoring and alerts on key system information.
- **Access Controls**: SSO, role-based, and system-level access controls are available.

# Load and Analyze Data

End-to-end tutorial: connect to Ocient, create a database and table, load sample data with a data pipeline, validate the results, and run analytic queries.

This tutorial details the core Ocient® workflow from start to finish. You connect to the system, create a database and table, load sample data from a source, validate the loaded data, and execute analytic queries.

The example uses a sample data set that covers every supported Ocient data type. By the end of this process, you have a working table with loaded data that you can query immediately.

## Prerequisites

The tutorial requires:

- Network access to the SQL Nodes in your Ocient System and the IP address or hostname of at least one SQL Node.
- A valid username and password with permissions to create databases, tables, and data pipelines.
- You have installed the Ocient JDBC driver and CLI on your local machine. For setup instructions, see **Connect Using JDBC**.

> If you do not have the JDBC driver installed, you can also connect using `pyocient`, the Ocient Python® driver. For setup instructions, see **Connect Using pyocient**.

## Step 1: Connect to the Ocient System

Start the JDBC CLI and connect to a SQL Node. Replace the hostname `<HOSTNAME_OR_IP>` and port `<PORT>` placeholders with the values for your system. The default SQL Node port is `4050`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

```sql
CONNECT TO jdbc:ocient://<HOSTNAME_OR_IP>:<PORT>/system;
```

After a successful connection, you see the Ocient CLI prompt.

```shell
Ocient> _
```

For details on connection methods and troubleshooting, see **Connect to Ocient**.

## Step 2: Create a Database and Schema

Create a database to hold your sample data. Using a dedicated database keeps your work isolated from other applications on the same system.

```sql
CREATE DATABASE test;
```

Switch your connection to the new database.

```sql
CONNECT TO jdbc:ocient://<HOSTNAME_OR_IP>:<PORT>/test;
```

Create a schema within the database to organize your tables.

```sql
CREATE SCHEMA loading;
```

For details on managing databases and schemas, see **Databases** and **Schemas**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Step 3: Create a Table

Create a table that covers all supported Ocient data types. This table serves as the target for the data pipeline in the next step.

The `CREATE TABLE` SQL statement defines the column names, data types, and a TimeKey® on the `col_timestamp` column in the `data_type_coverage` table. The TimeKey partitions data by time so that the system can skip irrelevant segments during time-filtered queries.

SQL

```sql
CREATE TABLE loading.data_type_coverage (
    col_bigint     BIGINT,
    col_binary     BINARY(2),
    col_boolean    BOOLEAN,
    col_char       CHAR(64),
    col_date       DATE,
    col_decimal    DECIMAL(18, 4),
    col_double     DOUBLE,
    col_float      FLOAT,
    col_int        INT,
    col_int_array  INT[],
    col_ipv4       IPV4,
    col_ip         IP,
    col_smallint   SMALLINT,
    col_point      POINT,
    col_linestring LINESTRING,
    col_polygon    POLYGON,
    col_time       TIME,
    col_timestamp  TIMESTAMP TIME KEY BUCKET(1, DAY) NOT NULL,
    col_tinyint    TINYINT,
    col_tuple      TUPLE<<INT, VARCHAR(255)>> NULL,
    col_uuid       UUID,
    col_varbinary  VARBINARY,
    col_varchar    VARCHAR
);
```

This table intentionally keeps the schema simple to focus on the loading workflow. In production, you should also define a Clustering Key and secondary indexes based on

your expected query patterns. For details on table design options, see:

- **TimeKeys and Clustering Keys** — Segment keys that partition and order data for faster queries.
- **Secondary Indexes** — Additional indexes for columns used in filters.
- **Table Compression Options** — Compression settings that reduce storage requirements.
- **CREATE TABLE SQL Statement Examples** — Examples of table definitions for different use cases.

# Step 4: Create a Data Pipeline

Data pipelines are the way to load data into an Ocient System. Each pipeline is a SQL object that defines the source, data format, and transformations for loading rows into one or more tables. For a full overview of pipeline concepts, see **Load Data**.

## Use a Sample Data Set

The sample data is a set of gzip-compressed CSV files hosted in a public Amazon® Web Services℠ (AWS℠) S3 bucket. Each file contains one header row followed by data rows with columns covering every Ocient data type.

## Create the Pipeline

This data pipeline reads CSV files from the S3 source, parses each field using named headers, applies type conversions where needed, and loads the results into the `data_type_coverage` table.

SQL

```
CREATE BATCH PIPELINE data_type_coverage_pipeline
    SOURCE S3
        ENDPOINT 'https://s3.us-east-1.amazonaws.com'
        BUCKET 'ocient-docs'
        PREFIX 'all_data_types/small/'
        FILTER_GLOB '**output*.csv.gz'
        COMPRESSION_METHOD 'gzip'
        SORT_BY 'filename'
    EXTRACT
        FORMAT delimited
        RECORD_DELIMITER e'\n'
        FIELD_DELIMITER ','
        FIELD_OPTIONALLY_ENCLOSED_BY '"'
        NUM_HEADER_LINES 1
        HEADERS [
            'bigint', 'binary', 'boolean', 'char',
            'date', 'decimal', 'double', 'float',
            'int', 'int_array', 'ipv4', 'ip',
            'smallint', 'point', 'linestring', 'polygon',
            'time', 'timestamp', 'tinyint', 'tuple',
            'uuid', 'varbinary', 'varchar'
        ]
        OPEN_ARRAY '['
        CLOSE_ARRAY ']'
        ARRAY_ELEMENT_DELIMITER ','
        OPEN_OBJECT '('
        CLOSE_OBJECT ')'
INTO test.loading.data_type_coverage
SELECT
    $bigint                                          AS col_bigint,
    $binary                                          AS col_binary,
    $boolean                                         AS col_boolean,
    $char                                            AS col_char,
    $date                                            AS col_date,
    $decimal                                         AS col_decimal,
    DOUBLE(IF(LOWER($double) = 'nan',NULL, $double)) AS col_double,
    FLOAT(IF(LOWER($float) = 'nan', NULL, $float))   AS col_float,
    $int                                             AS col_int,
    INT[]($int_array)                                AS col_int_array,
    $ipv4                                            AS col_ipv4,
    $ip                                              AS col_ip,
```

```
    $smallint                                           AS col_smallint,
    $point                                              AS col_point,
    $linestring                                         AS col_linestring,
    $polygon                                            AS col_polygon,
    $time                                               AS col_time,
    REPLACE(REPLACE($timestamp, 'T', ' '), 'Z', '')     AS col_timestamp,
    $tinyint                                            AS col_tinyint,
    $tuple                                              AS col_tuple,
    $uuid                                               AS col_uuid,
    VARBINARY(IF($varbinary IS NULL, NULL,
        IF(LENGTH($varbinary) % 2 = 1, CONCAT('0', $varbinary), $varbinary)))
                                                        AS col_varbinary,
    $varchar                                            AS col_varchar;
```

The pipeline has three sections:

- `SOURCE` — Identifies the S3 bucket, file path prefix, and glob filter. The `COMPRESSION_METHOD` parameter indicates that the source files are gzip-compressed.
- `EXTRACT` — Defines the CSV format options, including delimiters, quoting, and the header names that the `SELECT` clause references. The `OPEN_ARRAY` and `CLOSE_ARRAY`, and `OPEN_OBJECT` and `CLOSE_OBJECT` parameters tell the parser how array and tuple values are encoded in the CSV data.
- `SELECT` — Maps each source field to a target column. Some fields require explicit type conversion. For example, `DOUBLE($double)` converts the extracted string to a `DOUBLE` value, and the nested `REPLACE` functions strip the `T` and `Z` characters from timestamps to match the Ocient `TIMESTAMP` format. This `VARBINARY` expression pads odd-length hex strings with a leading zero to ensure all rows that are not `NULL` convert to the `VARBINARY` data type.

For details on pipeline syntax and options, see **Data Pipelines**. For details on supported data formats, see **Data Formats for Data Pipelines**. For details on data type handling during loading, see **Data Types for Data Pipelines**. For the functions, see **Transform Data in Data Pipelines**.

## Step 5: Start and Monitor the Pipeline

Start the data pipeline to begin loading data using the `START PIPELINE` SQL statement.

SQL

```
START PIPELINE data_type_coverage_pipeline;
```

Check the pipeline status while it runs.

SQL

```
SHOW PIPELINE_STATUS;
```

Output

Text

```
database_name  pipeline_name                 table_names                          s
-------------- ------------------------------ ---------------------------------- -
test           data_type_coverage_pipeline    ["loading.data_type_coverage"]     R
```

Wait for the `status` column to show the `COMPLETED` status. You can execute the `SHOW PIPELINE_STATUS` statement again to check progress.

For larger data sets, the `percent_complete`, `records_processed`, and `records_loaded` columns update as the pipeline progresses.

For more detailed monitoring options, including system catalog tables and metrics endpoints, see **Monitor Data Pipelines**.

If the pipeline enters the `FAILED` status, see **Manage Errors in Data Pipelines** and **Data Pipeline Loading Errors**.

## Step 6: Validate the Loaded Data

After the pipeline completes, verify that the data loaded correctly before you begin analysis.

### Verify the Row Count

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Confirm that the number of loaded rows matches the pipeline metrics.

```sql
SELECT COUNT(*) AS total_rows
FROM loading.data_type_coverage;
```

Cross-reference this count with the `records_loaded` value from the `SHOW PIPELINE_STATUS` statement.

## Check the Time Range

Verify that the `col_timestamp` column covers the expected date range. Gaps in the range can indicate missing source files.

```sql
SELECT
    MIN(col_timestamp) AS earliest,
    MAX(col_timestamp) AS latest,
    COUNT(DISTINCT CAST(col_timestamp AS DATE)) AS distinct_days
FROM loading.data_type_coverage;
```

## Inspect for NULL Values

Check for unexpected NULL values in columns that should be populated.

```sql
SELECT
    COUNT(*)             AS total_rows,
    COUNT(col_bigint)    AS non_null_bigint,
    COUNT(col_double)    AS non_null_double,
    COUNT(col_timestamp) AS non_null_timestamp,
    COUNT(col_varchar)   AS non_null_varchar,
    COUNT(col_int_array) AS non_null_int_array,
    COUNT(col_tuple)     AS non_null_tuple
FROM loading.data_type_coverage;
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

If a column has significantly fewer non-NULL values than expected, review the source data and the pipeline `SELECT` transformations for parsing issues.

### Sample Records

Review a small set of records to confirm that type conversions applied correctly using the `LIMIT` keyword.

SQL

```sql
SELECT *
FROM loading.data_type_coverage
LIMIT 5;
```

## Step 7: Query the Data

With validated data in the table, you can begin running analytic queries. These examples demonstrate common query patterns across different data types.

### Aggregate Numeric Data

Compute summary statistics on the numeric columns. In this case, retrieve the count of rows, the minimum number of the `col_int` column, the maximum number of the `col_int` column, and the average of the numbers in the `col_smallint` column.

SQL

```sql
SELECT
    COUNT(*)           AS total_rows,
    MIN(col_int)       AS min_int,
    MAX(col_int)       AS max_int,
    AVG(col_smallint)  AS avg_smallint
FROM loading.data_type_coverage;
```

### Filter by Time Range

Use the `col_timestamp` TimeKey column to filter data efficiently. The Ocient System skips segments outside the specified time range of January 2024.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```sql
SELECT
    CAST(col_timestamp AS DATE) AS day,
    COUNT(*)                    AS row_count,
    COUNT(DISTINCT col_int)     AS distinct_ints
FROM loading.data_type_coverage
WHERE col_timestamp >= TIMESTAMP '2024-01-01 00:00:00'
  AND col_timestamp <  TIMESTAMP '2024-02-01 00:00:00'
GROUP BY CAST(col_timestamp AS DATE)
ORDER BY day;
```

## Query Geospatial Data

Inspect the geospatial columns loaded into the table for the first 10 rows using the `LIMIT` keyword.

SQL

```sql
SELECT
    col_point,
    col_linestring,
    col_polygon
FROM loading.data_type_coverage
WHERE col_point IS NOT NULL
LIMIT 10;
```

For details on geospatial functions and spatial queries, see **Geospatial Functions**.

## Explore Data Type Distributions

Summarize the distinct values and NULL rates for each column type.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```sql
SELECT
    COUNT(DISTINCT col_boolean)  AS distinct_boolean,
    COUNT(DISTINCT col_tinyint)  AS distinct_tinyint,
    COUNT(DISTINCT col_smallint) AS distinct_smallint,
    COUNT(DISTINCT col_int)      AS distinct_int,
    COUNT(DISTINCT col_uuid)     AS distinct_uuid
FROM loading.data_type_coverage;
```

For a full reference of SQL functions, see **Functions Overview**. For tips on writing queries that leverage segment keys and indexes, see **Query Performance Tuning**.

### Remove the Data Pipeline and Table

After you finish exploring the sample data, remove the `data_type_coverage_pipeline` pipeline.

SQL

```sql
DROP PIPELINE data_type_coverage_pipeline;
```

Remove the `data_type_coverage` table.

SQL

```sql
DROP TABLE loading.data_type_coverage;
```

Removing a pipeline removes the pipeline metadata from the system but does not affect the data already loaded into the target table. Whereas removing the table removes the data.

Get Started

# Work with AI Prompts

Draft high-quality prompts to help AI tools use Ocient documentation and SQL accurately, with copy-paste templates and guidance on anchoring on sources.

Use this guide to draft high-quality prompts to assist AI tools in using the Ocient® documentation and SQL dialect with greater accuracy.

The guide explains why drafting AI prompts for the Ocient documentation helps produce better results. These reasons include:

- Large models often default to generic SQL or other vendor syntax.
- Additional guidance helps scrapers navigate documentation libraries.
- The `llms.txt` index page provides the cleanest and AI-friendly entry point to the documentation.

## Key AI Prompt Recommendations

Follow these key recommendations for working with the Ocient documentation:

### 1 Include Ocient Documentation URLs

Start prompts with one or more links to anchor the model on authoritative content. In prompts, specify the AI index page **/llms.txt** to provide full documentation reference for models.

If relevant, include the exact topic URL (e.g., SQL reference, machine learning, data pipelines).

### 2 Explicitly Require Ocient SQL

In your prompt, specifically dictate to the AI model to use Ocient SQL, such as `Use Ocient SQL syntax` or `Do not use non-Ocient SQL variants`. Such text is particularly helpful to avoid generic responses for prompts that involve complex data types or Ocient-specific syntax for TimeKey®, secondary indexes, or DDL statements.

© 2026 Ocient, Inc

# AI Prompt Templates

Use these templates and fill in your question and context-setting information in the `< ... >` sections, while keeping the rest of the text intact.

### General Questions

This template is suitable for general questions for Ocient System usage. Use this context-setting text prior to asking your question.

Text

```
You are answering using the official Ocient documentation.
Start from https://docs.ocient.com/llms.txt and reference the linked pages there.
Use only Ocient SQL syntax in examples and explanations.
Do not include SQL features or syntax from other databases.

Question: <your question here>
```

### Create an Ocient SQL Query

This AI prompt helps ensure an AI tool adheres to Ocient SQL in the response. The performance of the generated SQL query depends on the specifics of your data. Edit the resulting SQL query to meet your needs.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Text

```
You are answering using the official Ocient documentation.
Start at https://docs.ocient.com/llms.txt and reference the linked pages there.
Use Ocient SQL syntax only; do not use Postgres/MySQL/Spark SQL or other variants.
If uncertain about any detail, cite the exact Ocient page used.

Task:
Draft an Ocient SQL query to achieve
<Describe the goal clearly, including relevant tables or columns and any filters or

Context (optional but helpful):
- Schema snippets, table snippets, or column types
- Performance or indexing considerations
- Any assumptions or edge cases

Output format:
1) A single Ocient SQL query
2) A brief explanation (2–3 sentences)
3) Citations to the specific Ocient documentation pages used

Reference pages (if applicable to the task):
<Point to any relevant reference pages.>
```

## AI Prompts for Specific Use Cases

For more accurate responses, use your prompt to point to the relevant page URL in the documentation. Each page in this table provides high-level usage information for the specified topic.

| Topic | URL |
|---|---|
| Loading | **/load-data** |
| Installation | **/install-an-ocient-system** |
| Machine Learning | **/machine-learning-model-functions** |
| Geospatial | **/geospatial-functions** |
| Data Types | **/data-types** |
| DDL Statements | **/data-definition-language-ddl-statement-reference** |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Topic | URL |
| --- | --- |
| Errors and Warnings | **/errors-and-warnings** |

## Troubleshooting Low-Quality Responses

If the responses from your AI prompts are inaccurate, try modifying them with these suggestions:

- For generic responses, add the `Use Ocient SQL only` text and also the SQL reminders in **Key AI Prompt Recommendations**.
- For functions that appear incorrect, ask the AI tool to navigate to `/llms.txt` and cite the specific page it referenced.
- For incorrect structure, provide a minimal schema snippet and restate data types (such as complex types of arrays, tuples, or matrices).
- If navigation or footer text appears, restate `Start from llms.txt, ignore navigation and footer content`.
- If the AI tool continues to have issues accessing the documentation, download the PDF of the Ocient documentation and upload it into the AI prompt.

# Connect to Ocient

Connect client applications to an Ocient SQL Node using JDBC, pyocient, or REST on the default port 4050 with automatic load balancing across nodes.

You can connect to any of the SQL Nodes in an Ocient® System to run queries or commands. The SQL Node is available by default on port `4050` at the IP address or hostname assigned to the SQL Nodes. When more than one SQL Node is present in the Ocient System, Ocient automatically loads balance connections between the nodes to even out the load across connections.

Ocient provides a JDBC driver and a Python® driver named `pyocient`. You can use any of these drivers to connect to an online Ocient System.

To connect from a client computer that can access the SQL Node using the network, follow any of the following examples. Note that you must have the IP address of the SQL Node and a valid username and password to connect.

- **Connect Using JDBC**
- **Connect Using pyocient**

> If you are unable to connect, check the logs on the SQL Nodes for issues or check the **Errors and Warnings** for more detail on error codes.

For supported third-party tools, see **Ocient Integrations**.

# Ocient Integrations

Explore Ocient integrations with popular analytics tools and platforms to enhance data processing and analysis capabilities across your existing systems.

Ocient® databases can integrate with various industry tools and applications to expand their functionality.

The third-party tools listed in this section are certified to work with Ocient hyperscale systems. The included tutorials are intended to explain any requirements, setup instructions, and additional specifications needed for the applications to work fully with Ocient Systems.

Database tools not included in this section can still function with Ocient Systems.

## Supported Ocient Integrations

- **Looker Connector**
- **Superset Integration**
- **DBeaver Integration**
- **Metabase Integration**
- **SQLAlchemy Integration**
- **Tableau Integration**

For monitoring and observability integrations, see **Datadog Integration** and **Prometheus Metrics Endpoint**.

Ocient Systems assume that all date and time data is in UTC format. Therefore, third-party tools can require time zone configuration to get accurate results on date and time functionality. To configure the time zone settings for integrated applications, refer to the documentation for the respective tools.

For more information, see the **Time Zone Functions** section.

# Looker Connector

Connect Looker Studio to an Ocient System using the Google Apps Script community connector to visualize warehouse data in interactive dashboards and reports.

Google® Looker™ Studio is a free, online data visualization and business intelligence tool for connection to various data sources and creation of interactive dashboards and reports.

This connector enables clients to fetch data from an Ocient® System for visualization in Looker Studio using the **Google Apps Script** platform.

## Prerequisites

To use Looker Studio with the Ocient System, you must have this software:

- Ocient System — Use the latest version.
- A Google® account with login credentials.

## Connect to Ocient

Follow these steps to connect Looker Studio to your Ocient System.

1. Open Looker Studio and start a data source.
   - Go to **https://lookerstudio.google.com/** and sign in.
   - On the home page, select:
     - **Create** > **Data source**, or
     - From an open report, **Resource** > **Manage added data sources** > **Add a data source**.
2. Select the Ocient Community Connector.
   - In the connector gallery, go to the **Partner Connectors** section.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- Find and select the **Ocient DB** connector.

Looker Studio opens the **Ocient Connector** configuration page in the same tab.

3 Complete the configuration page by entering text in the fields. On the configuration page, select the **Allow to be modified** checkbox next to each field to modify it.

This table contains descriptions for each field.

| Field | Description |
|---|---|
| **Hostname** | Hostname or IP address of the Ocient SQL Node. |
| **Database** | Database name in the Ocient System. |
| **User** | Ocient username. |
| **Password** | Password for the Ocient username. |
| **Table** | Ocient table name ( `schema.table` ). |
| **Row Limit** | `LIMIT` value to add to queries. |
| **Date Range Column Name** | Column name for the `DATE` or `TIMESTAMP` column in the `WHERE` clause. |
| **Sort Column** | Column name for the `ORDER BY` clause. |
| **Sort Order** | Sort order with the option of `ASCENDING` or `DESCENDING` . |
| **Unnest Option** | Specifies if array columns are unnested. |
| **Custom Query** | A query that overrides the query generated by the connector. The Looker data source panel shows only the columns included in this query.<br><br>In this mode, Looker Studio infers column data types from the sample output, and not a `DESCRIBE TABLE` SQL statement. |

- Select **Connect**.
- Select **Allow** when Looker Studio prompts you with "**Allow parameter sharing?**.

You can now use Looker Studio to create reports for your Ocient System.

Looker Studio uses autocomplete in its filter tool, which can impact date or time filtering for records older than 28 days.

To fix this issue, navigate to the Looker filter control and set **Show suggested values** to `off`.

## Ocient Data Types in Looker Studio

The connector represents Ocient data types using the closest approximation supported by Looker Studio. The inference of data types happens in Looker Studio in these ways:

- In normal mode, the connector generates data types from the table schema produced by a `DESCRIBE TABLE` SQL statement.
- In custom query mode, Looker Studio infers data types from sample output.

This table shows how Ocient data types correspond to Looker Studio data types.

| Ocient Data Type | Looker Studio Data Type | Limitations |
|---|---|---|
| BOOLEAN | BOOLEAN | None |
| TINYINT,<br>SMALLINT,<br>INT,<br>BIGINT,<br>DOUBLE,<br>FLOAT,<br>DECIMAL | NUMBER | None |
| CHAR<br>VARCHAR<br>BINARY<br>HASH<br>IPV4<br>IP<br>UUID<br>VARBINARY<br>TIME | TEXT | None |
| POINT<br>LINESTRING<br>POLYGON | TEXT | Looker Studio Community Connectors can use latitude or longitude coordinates, but they do not support native WKT geospatial types. |
| DATE | YEAR_MONTH_DAY | None |
| TIMESTAMP | YEAR_MONTH_DAY_SECOND | None |

| Ocient Data Type | Looker Studio Data Type | Limitations |
| --- | --- | --- |
| CHAR[],<br>VARCHAR[],<br>BINARY[],<br>HASH[],<br>IPV4[],<br>IP[],<br>UUID[],<br>VARBINARY[],<br>TUPLE[] | TEXT | Looker Studio does not support arrays or tuples as a native data type. The connector represents container data types as textual strings.<br><br>For arrays, use the **Unnest Option** configuration field to flatten array columns for analytics.<br><br>For tuples, use the **Custom Query** field to extract the tuple elements. Setting the **Unnest Option** field does not work for flattening tuples. |

# DBeaver Integration

Learn how to integrate Ocient with DBeaver, enabling a powerful and intuitive interface for managing and analyzing your Ocient data.

DBeaver is a free and open-source application for database administration and SQL querying.

## Prerequisites

To use DBeaver with the Ocient® System, you must have these software prerequisites:

- Ocient System — Use latest version.
- JDBC Driver — Use latest version. See the Ocient Apache® Maven™ **repository** for a list of all versions.

To install, download the latest version of DBeaver from the **DBeaver Community** for your respective operating system.

Follow the installation steps and open DBeaver.

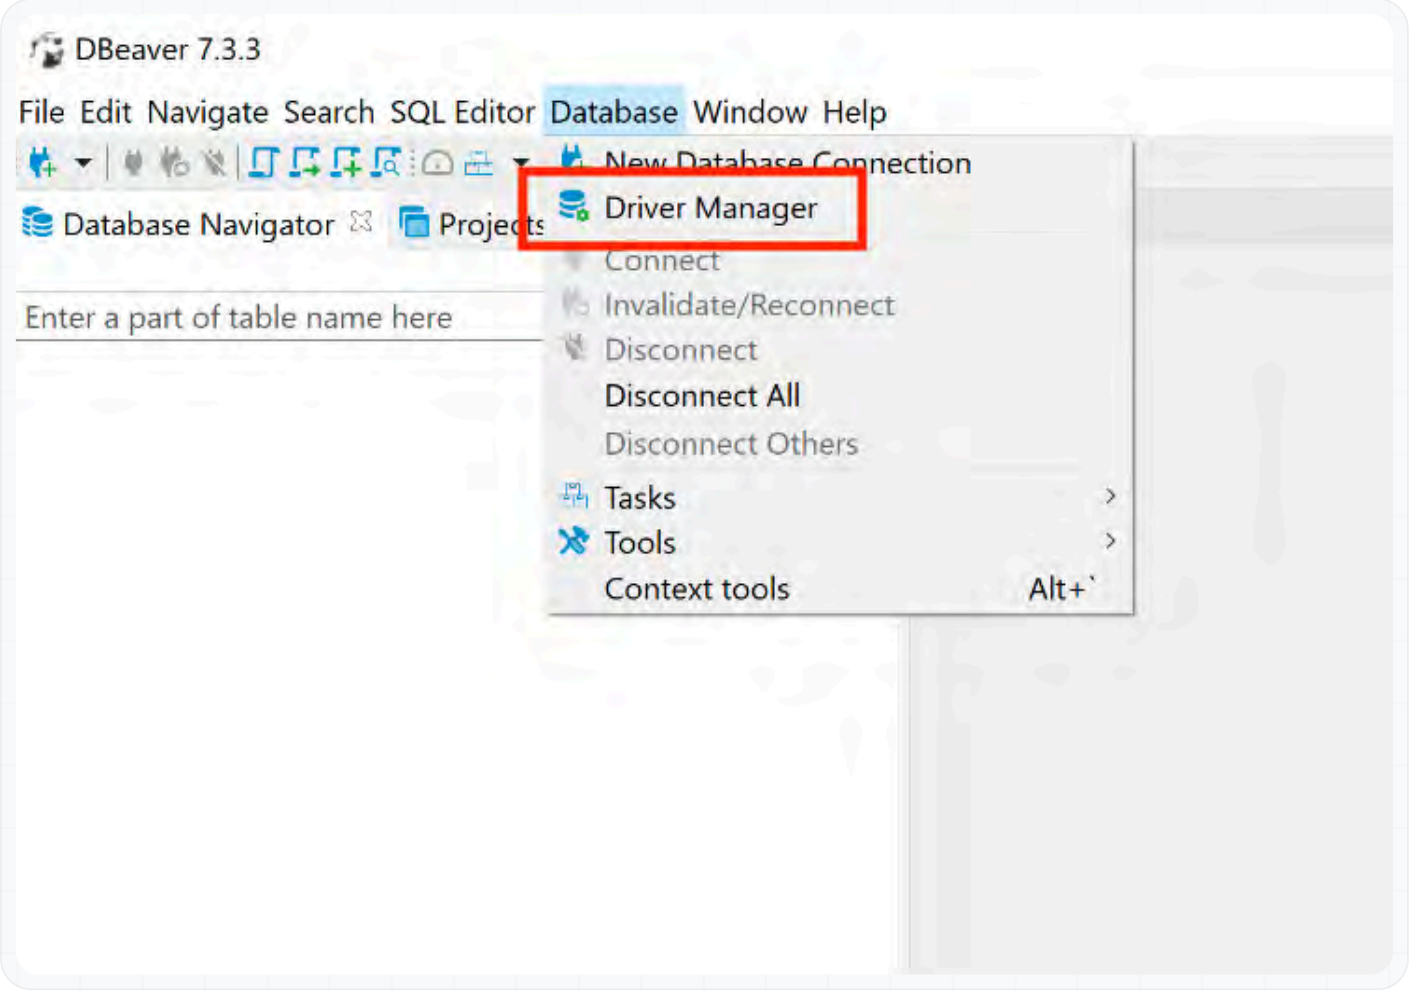
## Connect to Ocient

You can connect to your database by following these steps:

- In the main DBeaver window, select **New Database Connection** in the top left of the window.
- In the New Database Connection window, find the Ocient driver. Select it, and then select **Next**.
- Enter your database parameters with this information.

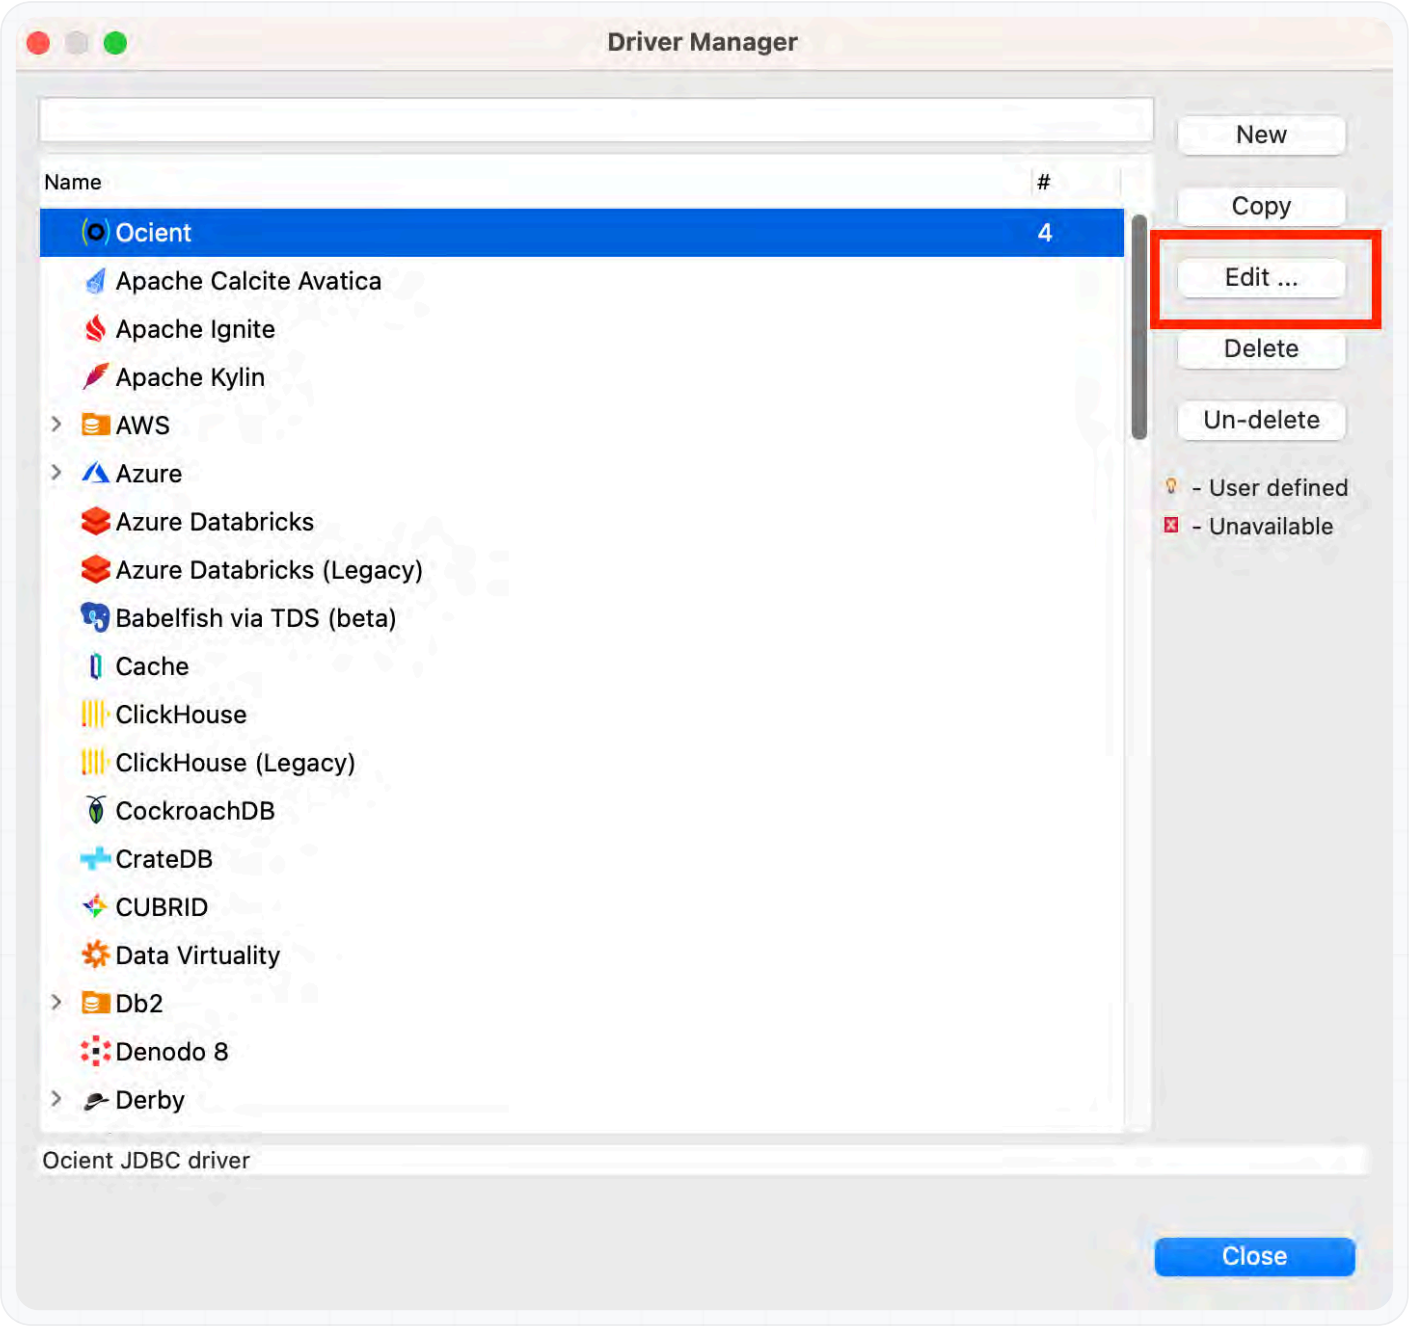
| Field | Description |
|---|---|
| Host | The hostname or IP address of the SQL Node of your Ocient System. For example: `databasehost-sql0` |
| Port | The port number for your connection. The default Ocient port is `4050`. |
| Database/Schema | The name of the database for connection. For example: `my_db` |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential



| Field | Description |
| --- | --- |
| User | The username associated with your database. |
| Password | The password associated with your username. |

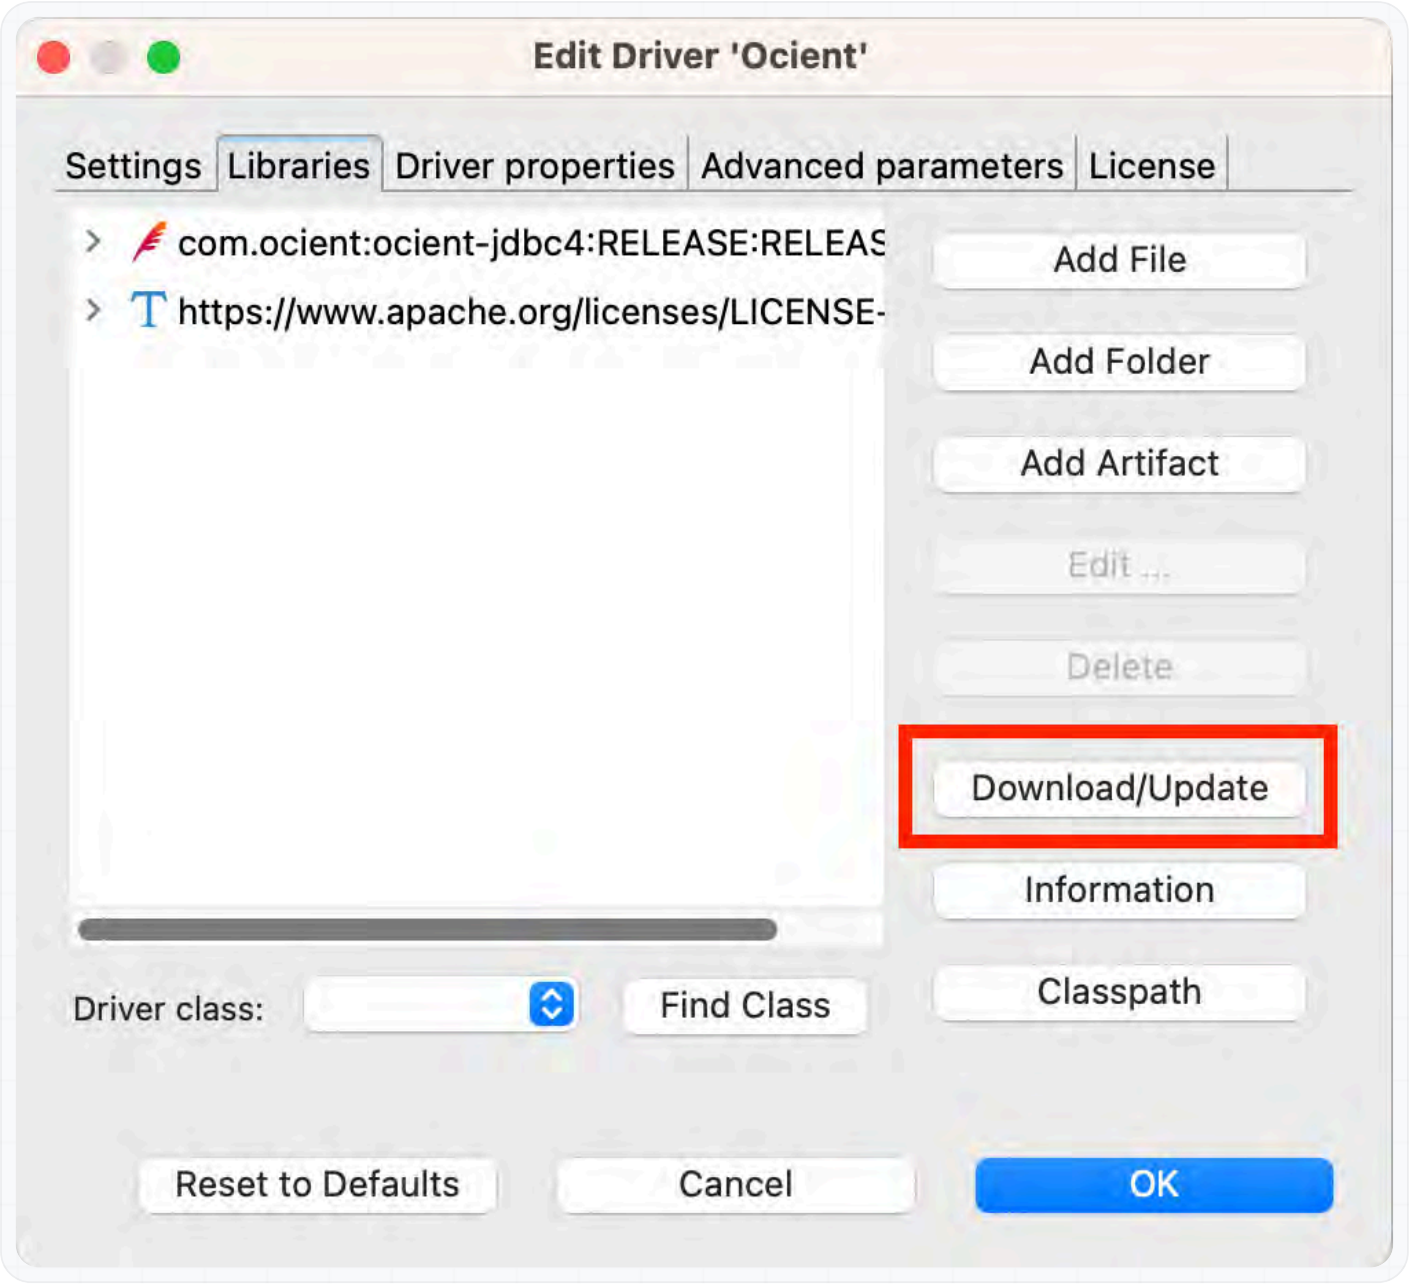
- Select **Finish**.



## Update Ocient JDBC

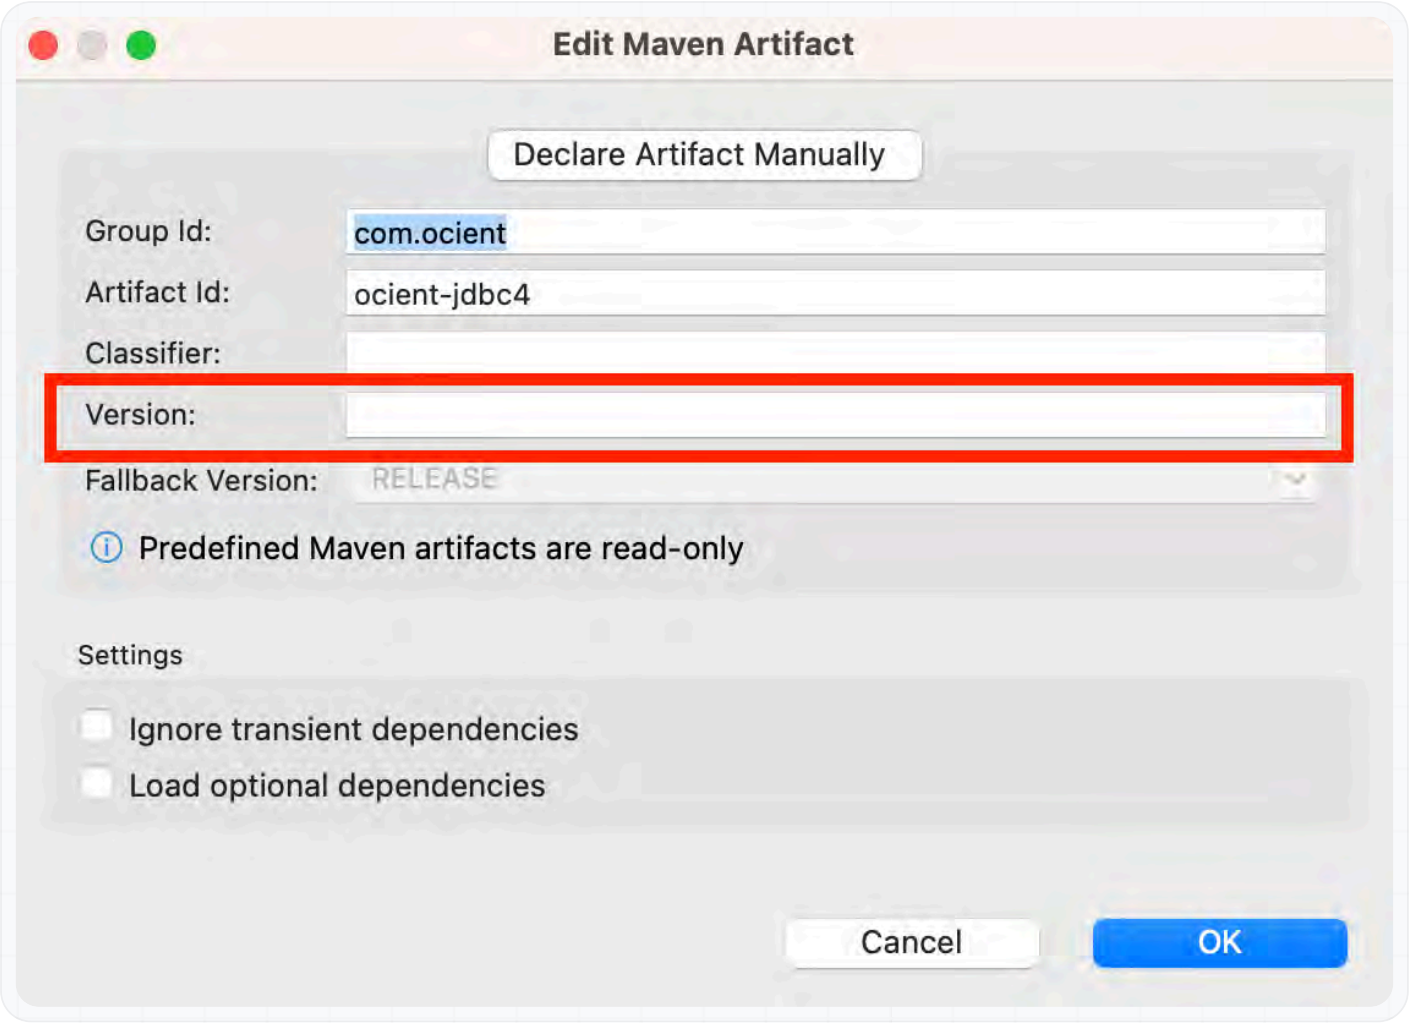
By default, DBeaver downloads the latest JDBC version available in the **Maven repository**. If you need to update the JDBC driver or load a specific version, follow these steps.

- In the DBeaver window, select **Database** > **Driver Manager**.



- Search among the list of driver options to find the Ocient driver, and select it.
- With the Ocient driver highlighted, select **Edit**.

- In the Edit window, select the **Libraries** tab.



### Update the Driver to the Latest Version

To update the driver to the latest version, select **Download/Update**.

### Load a Specific JDBC Driver Version

- Double-click the `com.ocient:ocient-jdbc4:RELEASE` entry in the Libraries window. The Edit Maven Artifact window opens.
- Enter the JDBC version in the **Version** field.

For accurate time values, you might need to configure the DBeaver time zone settings.

- For macOS® systems, configure this setting in **Settings** > **User Interface**.
- For Windows® systems, configure this setting in **Preferences** > **User Interface**.

# Metabase Integration

Integrate Ocient with Metabase to build dashboards and visualizations using JDBC, including driver setup, connection settings, and example queries.

Metabase℠ is an open-source business intelligence tool designed to create charts and dashboards from various data sources.

## Prerequisites

To use Metabase with your Ocient® System, you must have these software prerequisites:

- Ocient System — Use version 22.0 or later.
- JDBC driver — Use the latest version.

## Install Metabase

1. Go to the **Installing Metabase** and follow the directions for installation, including all prerequisites.
2. Download the latest **ocient-metabase-driver.jar** file and copy it to your Metabase plugins folder. This JAR file enables your Metabase installation to connect to Ocient.

## Connect to Ocient

To add a database connection, select the ⚙ icon at the top right of the Metabase homepage. Select **Admin settings > Databases > Add database** in the menu.

This connection page appears. The displayed connection fields change after you select **Ocient** as the database type.

Enter these fields in your connection settings.

| Field | Description |
|---|---|
| Database type | The type of database. Select **Ocient**. |
| Display name | The display name for your database in Metabase. |
| Host | The host name or IP address of the SQL Node of your database. For example: `databasehost-sql0` |
| Port | The port number for your connection. Unless you have to alter this, the default Ocient port is `4050`. |
| Database name | The name of the database for connection. For example: `my_db` |
| Schemas | The identifiers for any schemas you want to use or exclude. To use all available schemas, select `All`. |
| Authentication method | Choose between `Single Sign-On (Token)` for single sign-on (SSO) or `Password` for password authentication. |
| User | The username associated with your database. |
| Password | The password associated with your username. |
| Type of SSO token | Use `access_token`. |
| SSO token | Specify your SSO access token string. |

ⓘ To use SSO authentication, you must have SSO integration enabled for the specified database and group. For more information, see **ALTER DATABASE SET SSO INTEGRATION**.

When you successfully connect, you see your database added to Metabase. Your database appears as one of the active connections in Metabase.

Your database appears as one of the active connections in Metabase.

## Advanced Connection Options

You can add more connection settings as part of the JDBC connection string in Metabase. To add these, go to the **Add database** page and select **Show advanced options**.

You can specify options in the field **Additional JDBC connection string options**. In this image, the specified options include a maximum of 10,000,000 rows and a timeout of 0 milliseconds, using the `maxRows` and `timeoutMillis` parameters, respectively.

For a list of supported JDBC options, see the **JDBC Manual**.

# SQLAlchemy Integration

Connect Ocient with SQLAlchemy for efficient data querying and manipulation, enhancing SQL capabilities in your Ocient database environment.

**SQLAlchemy** is an open-source SQL toolkit and object-relational mapper for Python®.

## Prerequisites

To use SQLAlchemy, you must have these software packages:

- Ocient® System — Use the latest version.
- Python — Use version 3.5 or later.
- pyocient driver — Use the latest version. For details, see **pyocient Release Notes**.

## Installation

For information about installing SQLAlchemy, please see the **sqlalchemy-ocient** PyPI℠ page.

# Superset Integration

Integrate Ocient with Apache Superset for dynamic data visualizations and dashboards, empowering data-driven decision-making at scale.

Apache® Superset is an open-source business intelligence web application that can quickly generate visualizations, dashboard, and geospatial maps.

## Prerequisites

To use Superset with your Ocient® System, you must have these software prerequisites:

- Ocient System — Use the latest version.
- Python® — Use version 3.8 or later.
- SQLAlchemy — Install the latest version by using the **sqlalchemy-ocient** PyPI℠ page.
- pyocient driver — Use the latest version. For details, see **pyocient Release Notes**.

## Installation

To install, follow the **Installing Superset Locally Using Docker Compose** guide for your respective system.

## Connect to Ocient

For specific steps on connecting Superset to your Ocient System, see the **Ocient DB** page.

# Tableau Integration

Connect Ocient with Tableau to unlock advanced data visualization and reporting, driving actionable insights from massive data sets.

Tableau® is an interactive data visualization application designed to create charts and dashboards from various data sources.

## Prerequisites

To use Tableau with the Ocient® System, you must have these software prerequisites:

- Ocient System — Use the latest version.
- JDBC driver — Download the latest version with dependencies from the Apache® Maven™ **repository**. Select the **Versions** tab, choose your preferred version, and select the **Browse** link. Download the JAR file that is labeled with the pattern `ocient-jdbc4-<version number>-jar-with-dependencies.jar`.

## Installation

1. Download the latest version of Tableau Desktop for your respective operating system from the **Download Tableau Desktop** website.
2. Register and sign in to Tableau Desktop. Then, follow steps to complete the installation.

## Add Necessary Packages

To connect to Ocient, you must add these files to your Tableau installation:

- Ocient JDBC driver ( `.jar` ) — From the **Maven repository**, select the **Versions** tab, choose your preferred version, and select the **Browse** link. Download the JAR file that is labeled with the pattern `ocient-jdbc4-<version number>-jar-with-dependencies.jar`.
- Ocient Tableau connector file ( `.taco` ) — Download the latest version from **Tableau Exchange**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

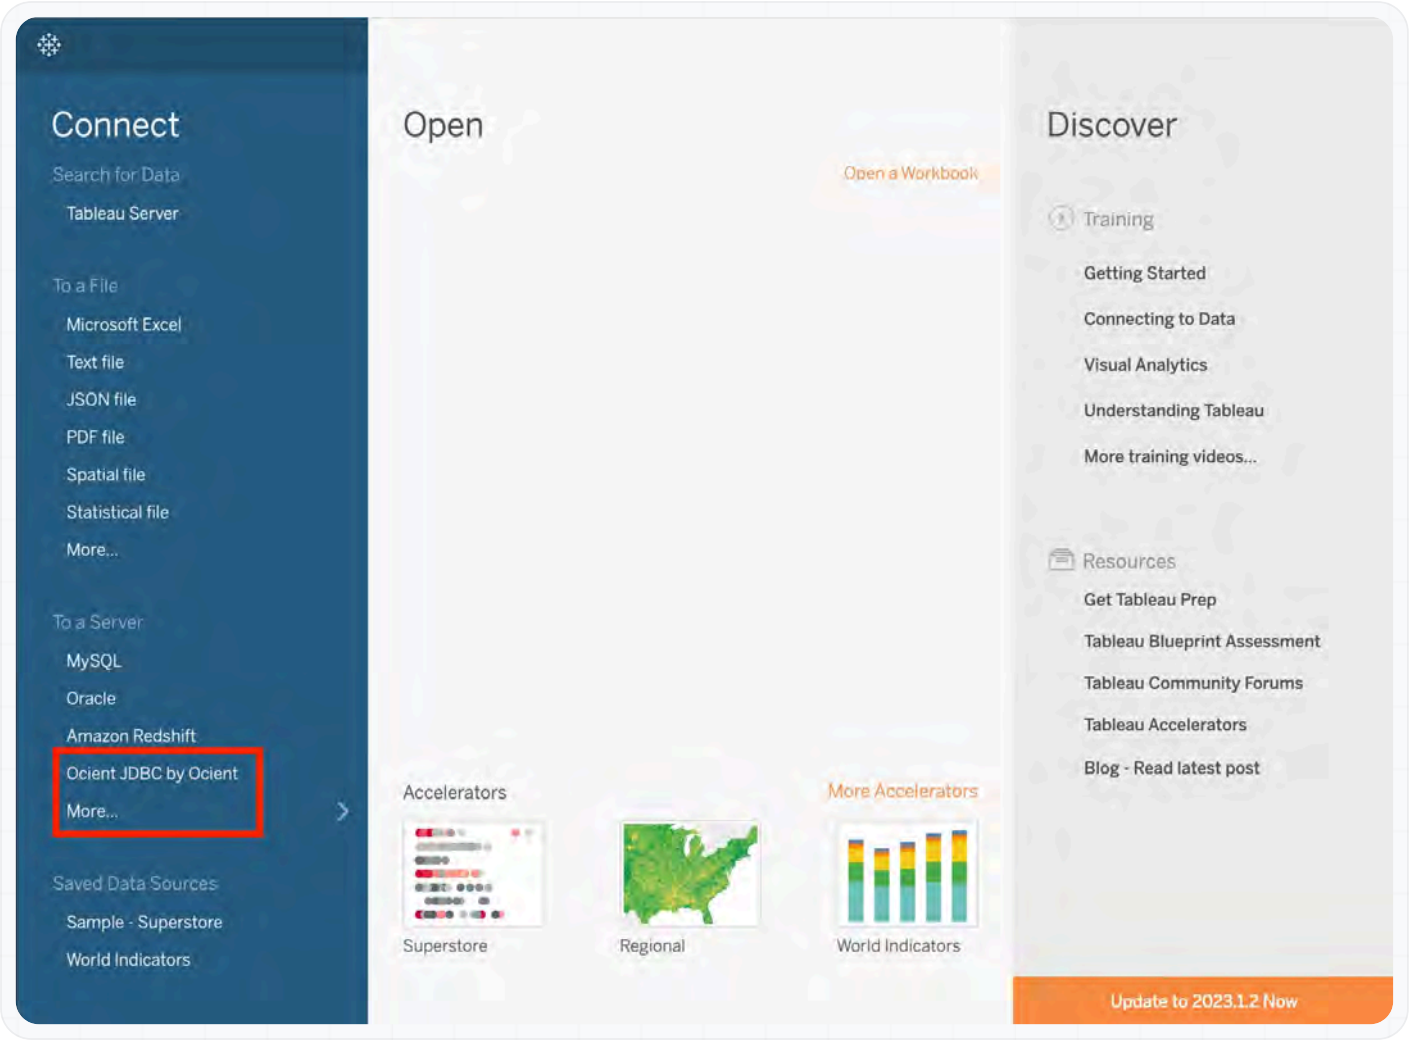
The `.taco` connector file supports Tableau Desktop and Tableau Server. Contact Tableau for support regarding Tableau Cloud.

### Add the Ocient JDBC Driver JAR File

Move the downloaded JDBC driver JAR file to the corresponding folder based on your operating system:

- Windows® — `C:\Program Files\Tableau\Drivers`
- macOS® — `/Users/[user]/Library/Tableau/Drivers`

### Add the Tableau Connector File ( `.taco` )



Move the downloaded `.taco` connector file to the corresponding folder based on your operating system:

- Windows — `C:\Users\[Windows User]\Documents\My Tableau Repository\Connectors`
- macOS — `/Users/[user]/Documents/My Tableau Repository/Connectors`

## Connect to Ocient

Connect to your database by following these steps:

- Open Tableau and find the **Connect to a Server** menu. Select **Ocient JDBC** from the list of installed connectors. If **Ocient JDBC** does not appear as an option in Tableau, ensure that the Ocient Tableau connector file ( `.taco` ) is located in the correct folder.

- In the connection window, enter your database parameters with this information.

| Field | Description |
|---|---|
| Host | The hostname or IP address of the SQL Node of your Ocient System. For example: `databasehost-sql0` |
| Port | The port number for your connection. The default Ocient port is `4050`. |
| Database | The name of the database for connection. For example: `my_db` |
| User | The username associated with your database. |
| Password | The password associated with your username. |

- Select **Sign In** after you enter all the information.

# Connect Using JDBC

Learn how to set up and configure a JDBC connection to Ocient, ensuring secure and efficient data access for large-scale analytics.

The JDBC driver can be executed in a command-line interface (CLI) mode or used directly in a program with standard JDBC methods. This example describes how to connect using the CLI mode. For details on using the JDBC driver in code, please see **Establishing a Connection**.

## Step 1: Download the JDBC Driver

First, confirm the recommended version of the JDBC driver for your version of Ocient® by finding it in **Version Compatibility**. Download the correct JDBC driver from the Apache® Maven™ **Central repository** by selecting the **Versions** tab, choosing your preferred version, and selecting the **Browse** link. Download the JAR file that is labeled with the pattern `ocient-jdbc4-<version number>-jar-with-dependencies.jar`.

Save this file to a convenient location on your client machine.

## Step 2: Run the JDBC CLI Program

To run the JDBC CLI Program, you must have Java® installed on your machine. For the version, see **Version Compatibility**. Next, run the following command to start the JDBC CLI Program. Assuming your JAR stored at `~/ocient-jdbc4-jar-with-dependencies.jar`.

Shell

```
java -classpath ~/ocient-jdbc4-jar-with-dependencies.jar com.ocient.cli.CLI
```

The system prompts you to enter the username and password.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

```shell
Username: test@system
Password: fakepassword
```

**Example Response:**

```shell
Ocient> _
```

The Ocient CLI prompt appears.

## Step 3: Connect

To connect, enter the connection string to your SQL Nodes. SQL Nodes install by default with a self-signed TLS certificate for encryption by default, and a custom certificate can be present. Depending on the TLS configuration, you can use `tls=unverified` (default) or `tls=on` for the required setting.

Assuming the standard port `4050`, a self-signed certificate, and the SQL Node IP Address of `10.10.1.1`, you can connect to the system database with the following connecting string:

```shell
Ocient> connect to jdbc:ocient://10.10.1.1:4050/system;
```

**Example Response:**

```shell
Connected to jdbc:ocient://10.10.1.1:4050/system
Ocient> _
```

© 2026 Ocient, Inc

You are now connected and can execute queries based on your user's permissions. Try running: `select * from sys.tables;` to see what tables are defined.

For more details on using the JDBC driver and the CLI program, see the **JDBC Manual**.

The system cancels any queries made with the JDBC driver if you perform any of these actions:

- Fetch the entire result set.
- Close the connection.
- Execute a new query on the same connection.

# Connect Using pyocient

Follow this guide to establish a Pyocient connection to the Ocient data warehouse, enabling Python-based data operations and analysis.

The Ocient® Python® module `pyocient` supports direct connections to Ocient Systems in a Command-Line Interface (CLI) as well as in Python programs that follow the Python Database API Specification 2.0.

After you install `pyocient`, you can establish Ocient connections to run queries and commands.

## Installation Tutorial

To install and run `pyocient`, follow these steps.

### 1 Install pyocient

Install `pyocient` using pip.

Shell

```
pip3 install pyocient
```

After running the pip install, `pyocient` is installed in the `bin` directory.

> Use `venv` to install `pyocient` using a virtual environment. For more information, see the Python **venv** documentation.

### 2 Start pyocient

`pyocient` is started from the command line with a connection string. It includes many options to configure the connection and client similar to the JDBC driver. Learn more about supported options in the **Ocient Python Module: pyocient**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

After installation, you can launch from a command line by typing the `pyocient` command.

Shell

```
pyocient ocient://example_user:example_password@10.10.1.1/system
```

To connect to the system database, replace the example username ( `example_user` ) and password ( `example_password` ) with your credentials, set your IP address,

The connection example assume a SQL Node exists at `10.10.1.1`. The example uses the default port `4050`, and is set up with default self-signed certificates for TLS.

**Example Response**

SQL

```
Ocient Database™
System Version: <Ocient System Version>, Client Version <pyocient Version>
> _
```

Use the command `quit;` to exit the `pyocient` CLI interface.

## 3 Run a Query

In the `pyocient` CLI, you can run any SQL query supported by your database. In this example, a query is selecting rows from the system tables:

SQL

```
SELECT * FROM sys.tables;
```

You can also run queries from the command line with the connection string:

Shell

```
pyocient ocient://example_user:example_password@10.10.1.1/system 'SELECT *
```

### Example Response

SQL

```
[
  {
        "id": "359e21b1-770a-4860-aec9-f158d307f725",
        "name": "data_type_coverage",
        "schema": "loading",
        "database_id": "f827ff7c-dd94-43bf-8386-93d048344a32",
        "storage_space_id": "2ad08e7c-15d1-4861-b38b-256c4df4a191",
        "maximum_segment_size_gib": 4,
        "description": null,
        "streamloader_property_string": null,
        "created_at": "2023-08-08T21:22:49.622213"
    }
]
```

The system cancels any queries made with the `pyocient` driver if you perform any of these actions:

- Fetch the entire result set.
- Close the connection.
- Execute a new query using the same connection.

For more information and API reference material for pyocient, see the **Ocient Python Module: pyocient** page.

# Load Data

Overview of Ocient data pipelines for SQL-based ETL: real-time transformations, deduplication, parallel processing, and support for S3, Kafka, and HDFS sources.

Loading data into the OcientAIQ™ Unified Data Platform using the data pipeline functionality is as simple as writing a SQL statement to query data from different supported sources. The loading operation provides real-time transformations and maximizes performance using all available processing resources.

With data pipelines, you manage data loading activities using Data Definition Language (DDL) statements similar to the ones used for managing database tables. You can access all information about pipelines by querying the system catalog tables. You can execute operations on pipelines with a command-line statement using standard interfaces like JDBC and ODBC.

> You can also create and manage data pipelines through the **Ocient Management UI**. The **Pipeline Builder** provides a guided workflow for creating pipelines without writing DDL, and the **Ingestion** page lets you monitor, start, and stop pipelines from a visual interface. The Pipeline Builder also saves an in-progress pipeline as a draft. While a draft exists, you cannot create, alter, or duplicate a pipeline until you resume or delete the draft.

## Data Pipelines Overview

A data pipeline is the primary way that the Ocient® System loads data. Each data pipeline is a database object that defines the end-to-end processing of data for the extraction, transformation, and load into Ocient tables. Data pipelines execute across your Ocient System to coordinate parallel loading tasks across many Loader Nodes and pipelines.

## The Pipeline Object

Creating a pipeline is complex as there are many options to consider. Use the `PREVIEW PIPELINE` SQL statement to preview the pipeline creation and load of data to ensure that the pipeline definition returns the results you expect. After you are satisfied with the results, you can execute the `CREATE PIPELINE` statement to create the pipeline at scale.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

For details, see the **CREATE PIPELINE** SQL statement. As an alternative to writing DDL, you can use the **Pipeline Builder** in the Management UI to create pipelines through a guided workflow.

When you create a pipeline, you assign it a name and the pipeline exists as an object in the Ocient System connected to this name. Then, you can control the object using your chosen name with SQL statements like `START PIPELINE`, `STOP PIPELINE`, `ALTER PIPELINE`, `CREATE OR REPLACE PIPELINE`, and `DROP PIPELINE`. You can also define your own function by using the `CREATE PIPELINE FUNCTION` SQL statement. Execute these statements using a SQL connection.

A pipeline maintains its own position during a load and enforces deduplication logic to ensure that the Ocient System only loads data once. The lifecycle of a pipeline defines both the deduplication logic and load position.

- Pipeline Events: During the life of a pipeline, you can start, stop, modify, and resume the pipeline without duplicating source data or losing the position in a load.
- Pipeline Updates: You can modify pipelines using the `ALTER PIPELINE` SQL statement to update the transforms in a pipeline, but maintain the current position in the load. For details, see **Update a Pipeline**.
- Load Position: If target tables are truncated or if a target table is dropped and then recreated, the pipeline maintains its own position in the load and continues from its last position.

Pipelines also gracefully handles many error cases and system failure modes. The pipeline stores any errors that occur in the system catalog in association with the pipeline.

For more details on Deduplication and Error Tolerance settings, see:

- **Deduplication in Data Pipelines**
- **Error Tolerance in Data Pipelines**
- **START PIPELINE Reference**

## Parts of a Pipeline

Pipelines can operate in either a `BATCH` or `CONTINUOUS` mode based on how you plan to load your data. Or, for transactional batch loads, you can use the `TRANSACTIONAL` mode

with the optional `START FOREGROUND` clause.

The DDL for Data Pipelines has three sections.

| Section | Syntax |
| --- | --- |
| Data Source | `SOURCE ...` |
| Data Format | `EXTRACT FORMAT ...` |
| Transformations | `INTO table SELECT ...` |

Thus, for example, the full SQL syntax has this format for the `orders_pipeline` data pipeline. This syntax has an S3 data source and loads data into the `orders` table in the `public` schema. The `SELECT` SQL statement in the `CREATE PIPELINE` statement selects the `id`, `user_id`, `product_id`, and other columns from a table.

SQL

```
CREATE PIPELINE orders_pipeline
SOURCE
  S3
    ENDPOINT '...'
    BUCKET '...'
    FILTER '...'
EXTRACT
  FORMAT delimited
  ...
INTO "public"."orders"
SELECT
  $1 as id,
  $2 as user_id,
  $3 as product_id,
  ...
```

## Data Source

The `SOURCE` part in a pipeline defines the source of the data to load. This DDL part identifies the type of the source (e.g., Amazon® Web Services℠ (AWS℠) S3, Apache® Kafka®) as well as the details for the data that is relevant to the source (e.g., S3 bucket and filters, Kafka topic and consumer configuration).

- **Kafka Source Options**
- **S3 Source Options**
- **File-based Source Options**
- **SOURCE Options Reference**

## Data Format

The `EXTRACT` part in a pipeline defines the format of the data that the Ocient System extracts from the data source. This part includes the data format (e.g., delimited, binary, JSON) and the details about the records (e.g., record delimiter, how to treat empty data). In addition, the Ocient System extracts metadata that you can load into tables.

- **Loading Delimited and CSV Data**
- **Loading JSON Data**
- **Load Parquet Data**
- **Loading Binary Data**
- **Loading Metadata Values**
- **EXTRACT Options Reference**

## Transformations

The `INTO table SELECT ...` SQL statement defines the target tables where the data loads and uses a `SELECT` SQL statement to extract fields from the source data (e.g., CSV field index `$5`, JSON selector `$order.user_name`) and map them to target columns (e.g., `... as my_column`).

The `SELECT` statement in a pipeline can utilize a subset of SQL functions to convert the extracted data into the required format during loading (e.g., `TO_TIMESTAMP($my_date, 'YYYY-MM-DD')`).

> The selectors you use to extract data from the source records can differ based on the data format (e.g., `JSON` or `DELIMITED`).

- **Supported Transformation Functions**
- **Use Source Field References**
- **Supported JSON Selectors**

For loading workflows, see these examples:

- **Data Pipeline Load of CSV Data from S3**
- **Data Pipeline Load of JSON Data from Kafka**
- **Data Pipeline Load of JSON Data from HDFS**
- **Data Pipeline Load of Parquet Data from S3**

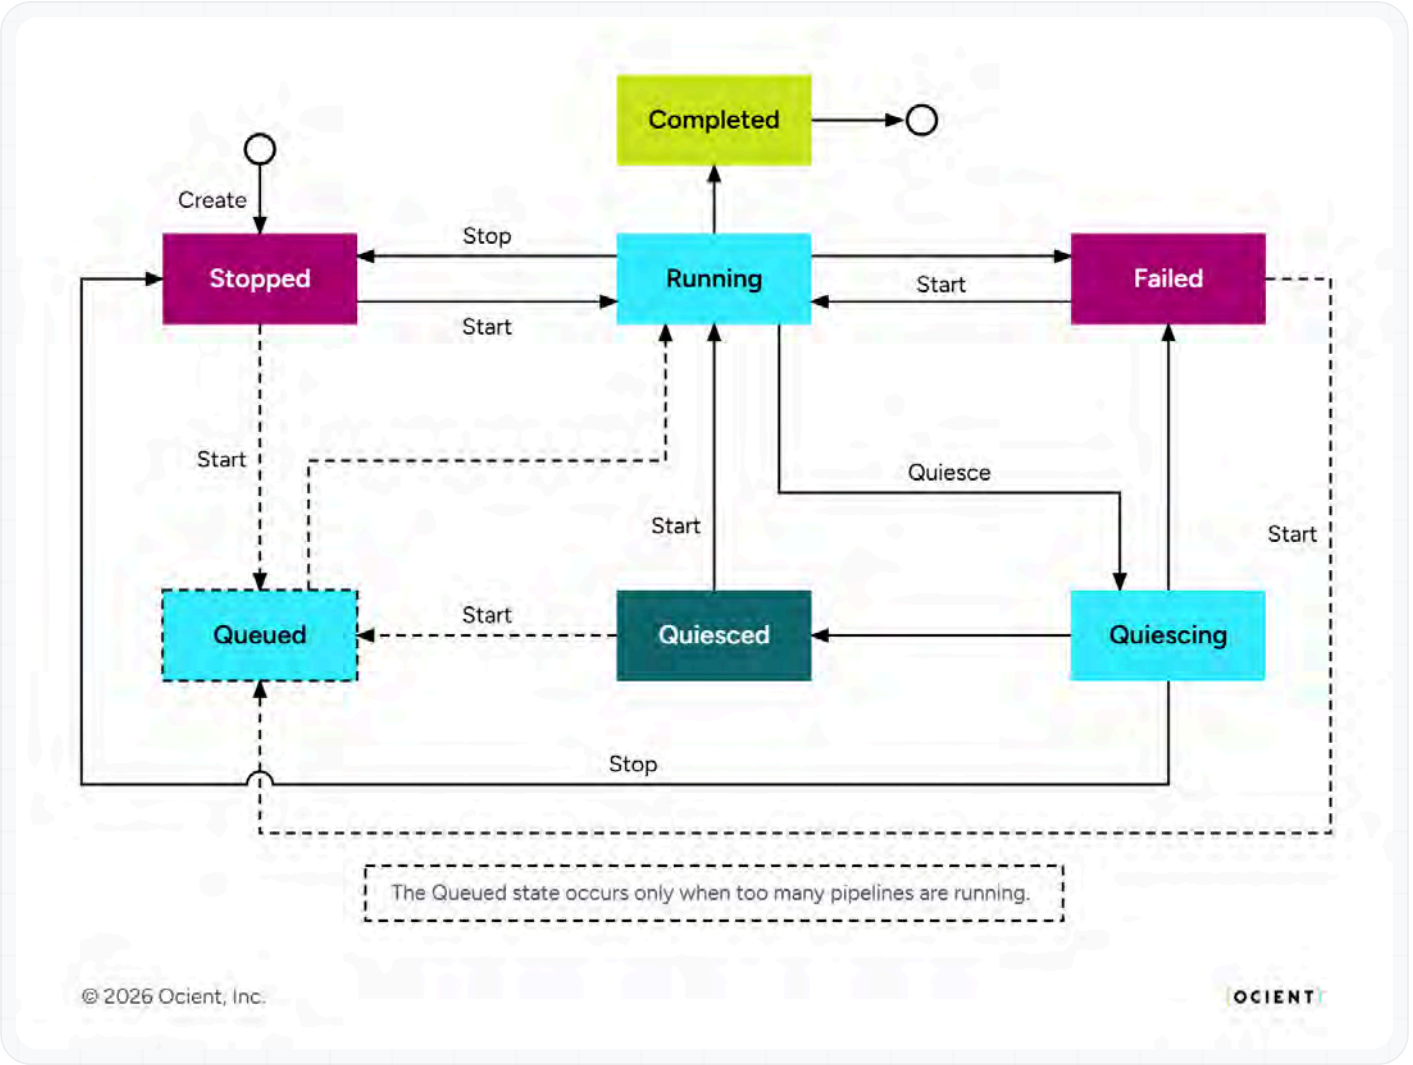
# Pipeline Lifecycle

This state machine shows the state transitions for a data pipeline. You can start and stop data pipelines using DDL statements. The status of the pipeline transitions automatically as the pipeline completes all assigned work or reaches a failed state.

While executing, the pipeline lists files or connects to streaming sources and creates tasks to execute work. These states reflect the overall progress of a pipeline and capture details of the underlying tasks that execute the work of the pipeline.

| State | Description |
|---|---|
| Stopped | The pipeline is not processing data. A newly created pipeline has the `STOPPED` status before a user starts it, and a running pipeline transitions to this status after a user stops it.<br>* All tasks are in the `QUEUED`, `COMPLETE`, `FAILED`, or `CANCELLED` states. |
| Queued | The pipeline is waiting to start. A user has issued `START PIPELINE`, but the Ocient System has not yet placed the pipeline into the `RUNNING` state (for example, because the pipeline is waiting for an available execution slot). The pipeline transitions automatically to `RUNNING` after the system schedules it. |
| Running | The pipeline is running after a user starts the pipeline.<br>* At least one task is in the `QUEUED`, `RUNNING`, or `CANCELLING` states.<br>* At least one file listed or Kafka Consumer group created. |
| Quiescing | The pipeline is stopping gracefully. A user executes the `QUIESCE PIPELINE` SQL statement, and the Ocient System is draining in-flight work before the pipeline becomes idle. The system creates no new work units. The pipeline transitions automatically to the `QUIESCED` status after the in-flight work finishes. |
| Quiesced | The pipeline has finished quiescing and is paused. No work is in flight, all loaded data is durable, and no partially loaded files remain. A user can resume the pipeline with the `START PIPELINE` SQL statement. |
| Completed | The pipeline finishes all assigned work according to the error limits defined for the pipeline.<br>* All tasks are in the `COMPLETE` state. |

| State | Description |
| --- | --- |
| Failed | The pipeline failed to complete and no longer runs due to error limits defined for the pipeline.<br>* At least one task is in the `FAILED` state.<br>* All tasks are in the `QUEUED`, `COMPLETE`, `FAILED`, or `CANCELLED` states. |



The actions that are available for a pipeline depend on its current status.

| Action | Allowed Statuses |
| --- | --- |
| `START PIPELINE` | `STOPPED`, `FAILED`, `QUIESCED` |
| `STOP PIPELINE` | `RUNNING`, `QUIESCING` |
| `QUIESCE PIPELINE` | `RUNNING` |
| `ALTER PIPELINE` | Any status except `RUNNING`, `QUEUED`, and `QUIESCING` |
| `DROP PIPELINE` | Any status except `RUNNING` and `QUIESCING` |

In this state diagram, the transition arrows display the user actions that can trigger a state change. State transitions without a label are system-initiated transitions.

When there are too many data pipelines in the system and you start a pipeline, the system moves pipelines to the `QUEUED` status.

Ocient Proprietary and Confidential

## Observe Pipelines

During pipeline operation, all of the information you need to observe progress, pipeline status, key events, success or failure, and errors is available in system catalog tables in the Ocient System. In addition, performance counters are available for many key loading metrics that you can add to observability systems.

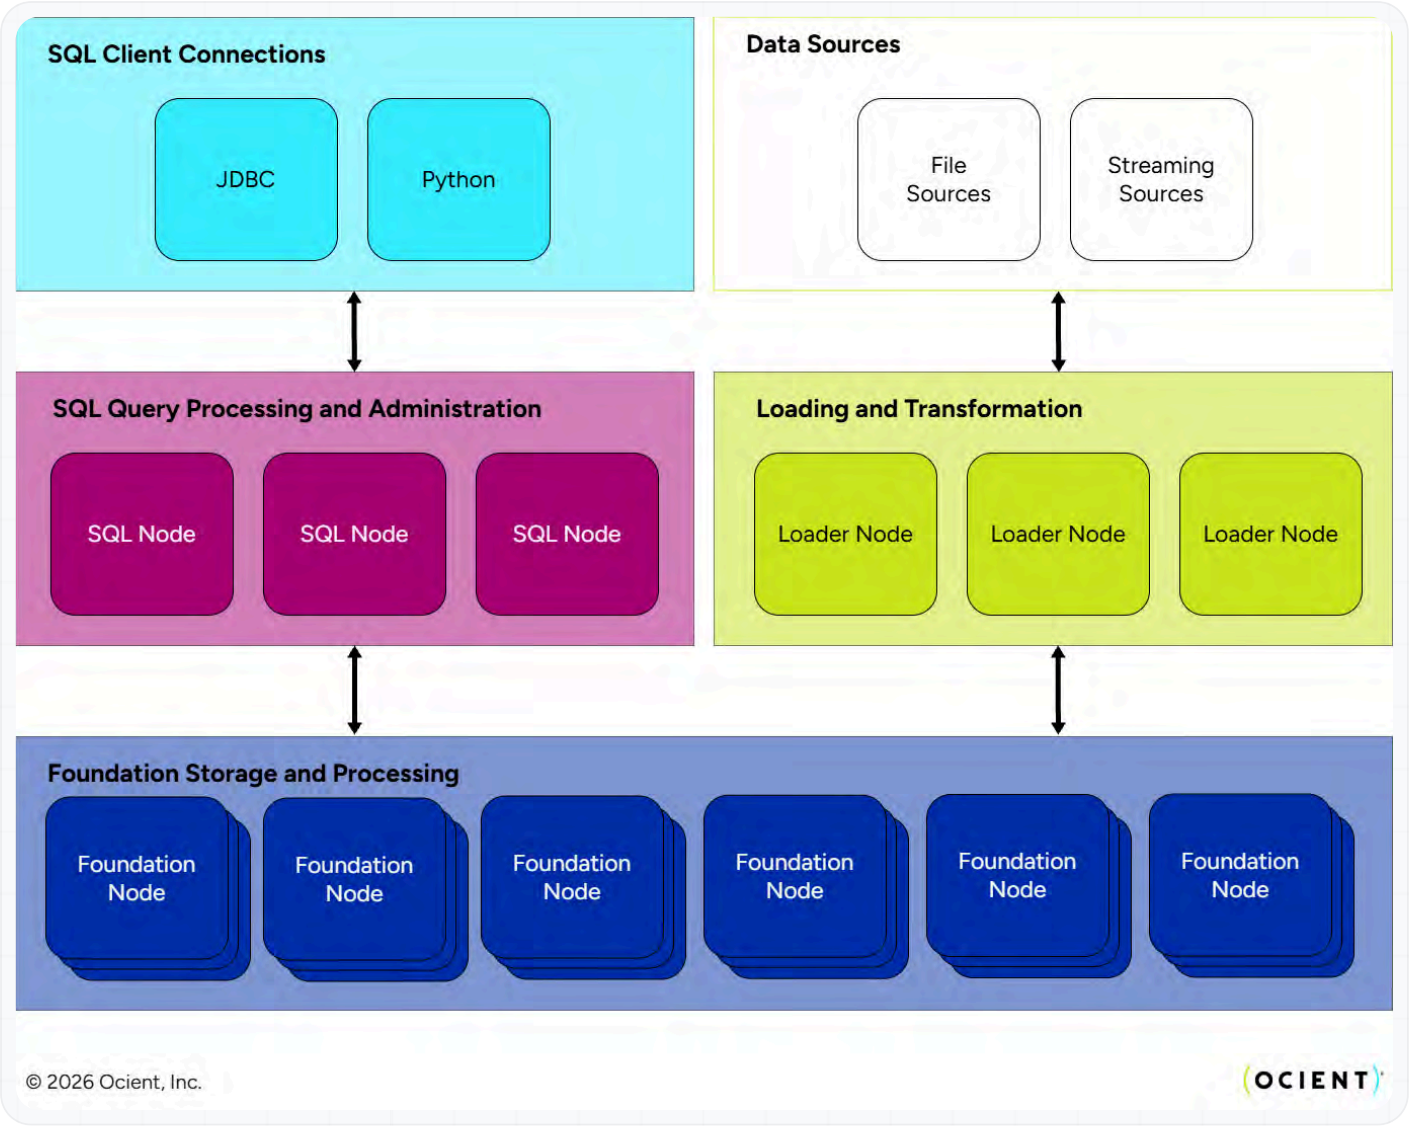
- **Monitor Data Pipelines**
- **System Catalog**

The Management UI **Ingestion** page provides a visual overview of all pipelines with their status, throughput, and error counts.

## Troubleshooting Pipelines

Data pipelines support robust error-handling capabilities crucial for developing new pipelines, identifying issues with ongoing operations, and correcting bad data. Pipelines can include a bad data target where the Ocient System saves bad data for troubleshooting. In addition, the system captures errors that you encounter during loading in system catalog tables such as `sys.pipeline_events` and `sys.pipeline_errors`. Exploring the data in these tables enables you to detect issues and identify the root cause of errors during loading.

- **Manage Errors in Data Pipelines**
- **Frequently Asked Questions for Data Pipelines**
- **Data Pipeline Loading Errors**
- **Bad Data Targets Reference**
- **Error Handling Options Reference**



## Loading Architecture

Pipelines require Loader Nodes to operate. Loader Nodes are Ocient Nodes that have the `streamloader` role assignment. The loading system can use all active nodes with this role to process pipelines.

When you execute a pipeline, Ocient spreads the work among the available Loader Nodes. The system executes these parallel processes as tasks on each of the Loader Nodes. Then, the system partitions the files or Kafka partitions to load across the tasks, and loading proceeds in parallel. When all tasks are completed, the pipeline is completed. Many pipelines can run in parallel on the Loader Nodes, and these Nodes share resources.

The scale-out architecture of the Ocient System allows you to add more Loader Nodes as needed to expand the volume and complexity of pipelines that you can operate at the throughput required by your application.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

# Internal Operations of a Pipeline

As pipelines process records from a data source, the Ocient System builds these rows into a column-oriented storage structure called a page. The system optimizes pages for rapid ingestion of data. The system stores pages on Foundation Nodes to ensure data integrity.

As pages accumulate, Loader Nodes convert pages into a columnar storage format named a Segment. Segments are highly compressed data structures that include data, indexes, and other statistical metadata to optimize query performance. After the Ocient System creates Segments, the system forms them into groups and transfers them to Foundation Nodes for storage.

You do not typically need to be concerned with or control these internal operations. However, it is important to understand that pipeline throughput can be affected by the parallel processing of many pipelines on shared resources, the number of indexes, and the type of compression used on your tables.

# Data Pipeline Load of CSV Data from S3

Load CSV data from AWS S3 into Ocient using a data pipeline. This tutorial covers database, table, and pipeline creation, execution, and monitoring.

A common setup for loading files in a batch into Ocient® is to load from a bucket on Amazon® Web Services℠ (AWS℠) S3 with time-partitioned data. Often, you must perform a batch load repeatedly to load new files.

Ocient uses data pipelines to transform each document into rows in one or more different tables. The loading and transformation capabilities use a simple SQL-like syntax for transforming data. This tutorial guides you through a simple example load using a small data set in CSV format. The data in this example comes from a test set for the Metabase℠ Business Intelligence tool.

## Prerequisites

This tutorial assumes that:

1. The Ocient System has network access to S3 from the Loader Nodes.
2. An Ocient System is installed and configured with an active Storage Cluster (See the **Ocient Application Configuration** guide).

## Step 1: Create a New Database

Connect to a SQL Node using the **Commands Supported by the Ocient JDBC CLI Program**. Then, execute the `CREATE DATABASE` SQL statement for a database named `metabase`.

SQL

```
CREATE DATABASE metabase;
```

## Step 2: Create Table

Create the `orders` table in the new database. First, connect to that database (e.g., `connect to jdbc:ocient://sql-node:4050/metabase`), and then execute this `CREATE TABLE` SQL statement that specifies to create a table with these columns and a clustering index based on the `user_id` and `product_id` columns:

- `created_at` as a TimeKey® timestamp that is not nullable.
- `id`, `user_id`, and `product_id` as integers that are not nullable.
- `subtotal`, `tax`, `total`, and `discount` as floating point numbers.
- `quantity` as an integer.

SQL

```
CREATE TABLE public.orders (
    created_at TIMESTAMP TIME KEY BUCKET(30, DAY) NOT NULL,
    id INT NOT NULL,
    user_id INT NOT NULL,
    product_id INT NOT NULL,
    subtotal DOUBLE,
    tax DOUBLE,
    total DOUBLE,
    discount DOUBLE,
    quantity INT,
    CLUSTERING INDEX idx01 (user_id, product_id)
);
```

The database creates the `orders` table, and you can begin loading data.

## Step 3: Create a Data Pipeline

Create data pipelines using the `CREATE PIPELINE` SQL statement. To load data, you first create a pipeline with the definition of the source, data format, and transformation rules using a SQL-like declarative syntax. Then, you execute the `START PIPELINE` SQL statement to start the load. You can observe progress and status using system tables and views.

Each Ocient pipeline defines a single data source and the target table or tables into which data loads. A data source includes the location of the source and filters on the

source to define the specific data set to load. This example loads data from a data source located in a directory within the S3 bucket.

First, inspect the data that you plan to load. Each document has a format similar to this example CSV file named `orders.csv`.

Text

```
id,user_id,product_id,subtotal,tax,total,discount,created_at,quantity
1,1,14,37.65,2.07,39.72,null,2019-02-11T21:40:27.892Z,2
2,1,123,110.93,6.1,117.03,null,2018-05-15T08:04:04.580Z,3
3,1,105,52.72,2.9,49.2,6.42,2019-12-06T22:22:48.544Z,2
...
```

In this case, Ocient automatically transforms the data to the target columns using some sensible conventions. In other cases, loads require some transformation. Most transformations are identical to functions that already exist in the SQL dialect of the Ocient System.

Create a pipeline named `orders_pipeline` for the orders data set from your database connection prompt. Use the S3 data source with endpoint `https://s3.us-east-1.amazonaws.com`, bucket `ocient-docs`, and filter `metabase_samples/csv/orders.csv`. Specify the CSV format with one header line. Load the data into the `public.orders` table. The `SELECT` part of the SQL statement maps the fields in the CSV file to the target columns in the created table.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE PIPELINE orders_pipeline
SOURCE
    S3
        ENDPOINT 'https://s3.us-east-1.amazonaws.com'
        BUCKET 'ocient-docs'
        FILTER 'metabase_samples/csv/orders.csv'
EXTRACT
    FORMAT csv
    NUM_HEADER_LINES 1
INTO public.orders
SELECT
    $1 as id,
    $2 as user_id,
    $3 as product_id,
    $4 as subtotal,
    $5 as tax,
    $6 as total,
    $7 as discount,
    $8 as created_at,
    $9 as quantity;
```

The pipeline has three main sections:

- `SOURCE` — In this case, load data from S3. Specify the endpoint and bucket. The `FILTER` parameter identifies the file or files to load. The load uses a single CSV file. Options exist to add wildcards or regular expressions to isolate different file sets.
- `EXTRACT` — Set the format to CSV files and note that there is one header line in the file. This specification skips that row when the Ocient System processes the file. Many other options exist for delimited data such as a record delimiter and field delimiter.
- `INTO ... SELECT` — Choose the target table `public.orders` and select the fields from the CSV file. The numeric index identifies each file field. Importantly, similar to other SQL syntax, the first field in the file is `$1`, not `$0`. Each field maps to a target column using the `as` syntax.

After you successfully create the `orders_pipeline` pipeline, execute the `START PIPELINE` SQL statement.

```sql
START PIPELINE orders_pipeline;
```

## Step 4: Observe the Load Progress

With your pipeline running, data immediately begins to load from the S3 files that you defined. If there are many files in each file group, the load process first sorts the files into batches, partitions them for parallel processing, and assigns them to Loader Nodes.

You can check the pipeline status and progress by querying `information_schema.pipeline_status` or by executing `SHOW PIPELINE_STATUS`

```sql
SHOW PIPELINE_STATUS;
```

*Output*

```sql
database_name         pipeline_name       table_names           status      status
-------------------------------------------------------------------------------------
metabase              orders_pipeline     ["public.orders"]     RUNNING     Starte
```

After the status of the pipeline changes to `COMPLETED`, all data is available in the target table.

After a few seconds, the data is available for query in the `public.orders` table.

```sql
SELECT COUNT(*) FROM public.orders;
```

*Output*

```
SQL
count(*)
--------------------
18760
```

You can drop the pipeline with the `DROP PIPELINE orders_pipeline;` SQL statement. Execution of this statement leaves the data in your target table, but removes metadata about the pipeline execution from the system.

# Data Pipeline Load of JSON Data from Kafka

Stream JSON data from Kafka topics into Ocient with data pipelines. Set up the database, table, pipeline, and SQL transformations for real-time analytics.

A common setup for streaming data into Ocient® is to load JSON data from an Apache® Kafka® topic.

Ocient uses data pipelines to transform each document into rows in one or more different tables. The loading and transformation capabilities use a simple SQL-like syntax for transforming data. This tutorial guides you through a simple example load using a small data set in JSON format. The data in this example comes from a test set for the Metabase℠ Business Intelligence tool.

## Prerequisites

This tutorial assumes that:

1. The Ocient System has network access to a Kafka broker from the SQL and Loader Nodes.
2. An Ocient System is installed and configured with an active Storage Cluster (see the **Ocient Application Configuration** guide).

## Step 1: Create a New Database

Connect to a SQL Node using the **Commands Supported by the Ocient JDBC CLI Program**. Then, execute the `CREATE DATABASE` SQL statement to create the `metabase` database.

SQL

```
CREATE DATABASE metabase;
```

## Step 2: Create Table

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Create the `orders` table in the new database. First, connect to that database (e.g., `connect to jdbc:ocient://sql-node:4050/metabase`), and then execute this `CREATE TABLE` SQL statement that specifies to create a table with these columns and a clustering index based on the `user_id` and `product_id` columns:

- `created_at` as a TimeKey® timestamp that is not nullable.
- `id`, `user_id`, and `product_id` as integers that are not nullable.
- `subtotal`, `tax`, `total`, and `discount` as floating point numbers.
- `quantity` as an integer.

SQL

```
CREATE TABLE public.orders (
    created_at TIMESTAMP TIME KEY BUCKET(30, DAY) NOT NULL,
    id INT NOT NULL,
    user_id INT NOT NULL,
    product_id INT NOT NULL,
    subtotal DOUBLE,
    tax DOUBLE,
    total DOUBLE,
    discount DOUBLE,
    quantity INT,
    CLUSTERING INDEX idx01 (user_id, product_id)
);
```

The database creates the `orders` table, and you can begin loading data.

## Step 3: Create a Data Pipeline

Create data pipelines using the `CREATE PIPELINE` SQL statement. To load data, you first create a pipeline with the definition of the source, data format, and transformation rules using a SQL-like declarative syntax. Then, you execute the `START PIPELINE` command to start the load. You can observe progress and status using system tables and views.

Each Ocient pipeline defines a single data source and the target table or tables into which data loads. A data source includes the location of the source and filters on the

source to define the specific data set to load. This example loads data from two data sources, where each source is located in a directory on the same S3 bucket.

First, inspect the data that you plan to load. Each document has a format similar to this example.

JSON

```
{"id": 1, "user_id": 1, "product_id": 14, "subtotal": 37.65, "tax": 2.07, "total"
{"id": 2, "user_id": 1, "product_id": 123, "subtotal": 110.93, "tax": 6.1, "tota
```

In this case, Ocient automatically transforms the data to the target columns using some sensible conventions. In other cases, loads require some transformation. Most transformations are identical to functions that already exist in the SQL dialect of the Ocient System.

Create a pipeline named `orders_pipeline` for the orders data set from your database connection prompt. Specify the Kafka source with broker address `192.168.0.1:9092` (replace this example Kafka broker address with your address) and topic `orders`. Load the data into the `public.orders` table. The `SELECT` part of the SQL statement maps the JSON fields to the target columns in the created table.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE PIPELINE orders_pipeline
SOURCE
    KAFKA
        BOOTSTRAP_SERVERS '192.168.0.1:9092'
        TOPIC 'orders'
EXTRACT
    FORMAT json
INTO public.orders
SELECT
    $id as id,
    $user_id as user_id,
    $product_id as product_id,
    $subtotal as subtotal,
    $tax as tax,
    $total as total,
    $discount as discount,
    $created_at as created_at,
    $quantity as quantity;
```

The pipeline has three main sections:

- `SOURCE` — Loads data from Kafka. Specify the address of the bootstrap servers and topic. Options exist to set Kafka consumer configurations.
- `EXTRACT` — Sets the format to JSON.
- `INTO ... SELECT` — Targets the `public.orders` table and selects the chosen fields from the JSON records. In this case, all data is available at the top level of the JSON records, so the example references the fields by the attribute name (e.g., `$id`, `$user_id`, etc.). For nested data, reference the nested fields using dot notation (e.g., `$order.user.first_name`). Each field maps to a target column using the `as` syntax.

After you successfully create this pipeline, execute the `START PIPELINE` SQL statement.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
START PIPELINE orders_pipeline;
```

## Step 4: Confirm that Loading is Operating Correctly

With the pipeline in place and running, data immediately begins loading off of the Kafka topics that are configured in the pipeline. If you do not have data in the Kafka topics yet, now is a good time to start producing data into the topics.

### Produce Test Data into Kafka

For test purposes, **kafkacat** is a helpful utility that makes it easy to produce records into a topic. For example, if you have a file of sample data `orders.jsonl` in a JSONL format (newline-delimited JSON records), you can run this command to send those records into your Kafka broker. Specify your broker IP address instead of `<broker_ip_address>` and your topic name `<topic_name>`.

Shell

```
kafkacat -b <broker_ip_address>:9092 -t <topic_name> -T -P -l orders.jsonl
```

Save an example document to your file system to use for this test. For this example, you can download an example file from **https://ocient-docs.s3.amazonaws.com/metabase_samples/jsonl/orders.jsonl** and save it to `~/orders.jsonl`.

Assuming the broker is running at the IP address `10.0.0.3`, send data into the `orders` topic defined in the pipeline definition by executing this command.

Shell

```
kafkacat -b 10.0.0.3:9092 -t orders -T -P -l orders.jsonl
```

This command pushes the entire JSONL file of messages into Kafka with one record per line. As these records are produced into Kafka, the running pipeline begins to load them into Ocient.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Step 5: Observe the Load Progress

With your pipeline running, data immediately begins to load from the Kafka topic. The pipeline creates parallel Kafka consumers for each partition. If there are more partitions than processing cores available, the pipeline automatically handles spreading consumers across available processing cores and Loader Nodes.

You can check the pipeline status and progress by querying `information_schema.pipeline_status` or executing the `SHOW PIPELINE_STATUS` SQL statement.

SQL

```
SHOW PIPELINE_STATUS;
```

*Output*

SQL

```
database_name          pipeline_name       table_names          status      status
-------------------------------------------------------------------------------------
metabase               orders_pipeline     ["public.orders"]    RUNNING     Starte
```

After a few seconds, the data is available for query in `public.orders`.

SQL

```
SELECT COUNT(*) FROM public.orders;
```

*Output*

SQL

```
count(*)
--------------------
18760
```

Unlike a batch file load, Kafka streaming pipelines run continuously, so they never change to a status of `COMPLETED`. To examine progress, you can use the information schema and system catalog tables. Key details are in `information_schema.pipelines`, `information_schema.pipeline_status`, and `sys.pipeline_partitions`.

For example, this statement shows the status and key metrics for duration, loaded records, and failed records.

SQL

```
SELECT
    pipeline_name,
    status,
    status_message,
    duration_seconds,
    records_loaded,
    records_failed
FROM
    information_schema.pipeline_status;
```

*Output*

SQL

```
pipeline_name    status    status_message                                    duration_s
-----------------------------------------------------------------------------------
orders_pipeline  RUNNING   Started processing pipeline orders_pipeline   10.089936
```

In this example, there are no errors. The `sys.pipeline_errors` system catalog table captures any errors that occur during the pipeline process.

You can drop the pipeline with the `DROP PIPELINE orders_pipeline;` SQL statement. Execution of this statement leaves the data in your target table, but removes metadata about the pipeline execution from the system.

# Data Pipeline Load of Parquet Data from S3

Load time-partitioned Parquet files from AWS S3 into Ocient tables with data pipelines and SQL transformations. Includes setup, execution, and monitoring.

A common setup for loading files in a batch into the Ocient® System is to load from a bucket on Amazon® Web Services℠ (AWS℠) S3 with time-partitioned data. Often, you must perform a batch load repeatedly to load new files.

The Ocient System uses data pipelines to transform each document into rows in one or more different tables. The loading and transformation capabilities use a simple SQL-like syntax for transforming data. This tutorial guides you through a simple example load using a small data set in Apache® Parquet™ format. The data in this example comes from a test set for the Metabase℠ Business Intelligence tool.

## Parquet Loading Recommendations

Follow this set of recommendations for an optimal loading experience of Parquet files.

### File Configuration

- Files should have row groups of less than 128 MB. Larger row groups can impact memory usage during loading, and row groups of 512 MB can cause loading failures on 1 TB or more data sets.
- Encoding fields in a Parquet file reduces the space of the file on disk but can impact memory usage during loading. Enable encoding on fields that you expect to have less than 256 unique values and for fields that contain short strings. You do not have to encode other fields.

### Multiple Files

- You can load row groups of multiple Parquet files in parallel. For large data sets, load the data set as multiple files.
- Loading files with differing schemas is not supported.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

# Prerequisites

This tutorial assumes that:

1. The Ocient System has network access to S3 from the Loader Nodes.
2. An Ocient System is installed and configured with an active Storage Cluster. For details, see **Ocient Application Configuration**.

# Parquet Loading Example

Follow these steps to load Parquet data into the Ocient System.

## Step 1: Create a New Database

Connect to a SQL Node using the **Commands Supported by the Ocient JDBC CLI Program**. Then, execute the `CREATE DATABASE` SQL statement to create the `metabase` database.

```sql
CREATE DATABASE metabase;
```

## Step 2: Create a New Table in the Database

Create the `orders` table in the new database. First, connect to that database (e.g., `connect to jdbc:ocient://sql-node:4050/metabase`), and then execute this `CREATE TABLE` SQL statement that specifies to create a table with these columns and a clustering index based on the `user_id` and `product_id` columns:

- `created_at` as a TimeKey® timestamp that is not nullable.
- `id`, `user_id`, and `product_id` as integers that are not nullable.
- `subtotal`, `tax`, `total`, and `discount` as floating point numbers.
- `quantity` as an integer.

SQL

```sql
CREATE TABLE public.orders (
    created_at TIMESTAMP TIME KEY BUCKET(30, DAY) NOT NULL,
    id INT NOT NULL,
    user_id INT NOT NULL,
    product_id INT NOT NULL,
    subtotal DOUBLE,
    tax DOUBLE,
    total DOUBLE,
    discount DOUBLE,
    quantity INT,
    CLUSTERING INDEX idx01 (user_id, product_id)
);
```

The database creates the `orders` table, and you can begin loading data.

## Step 3: Preview and Create a Data Pipeline

Create data pipelines using the `CREATE PIPELINE` SQL statement. To load data, you first create a pipeline with the definition of the source, data format, and transformation rules using a SQL-like declarative syntax. Then, you execute the `START PIPELINE` SQL statement to start the load. You can observe progress and status using system catalog tables and views.

Each Ocient pipeline defines a single data source and the target table or tables into which data loads. A data source includes the location of the source and filters on the source to define the specific data set to load. This tutorial loads data from two data sources, where each source is located in a directory on the same S3 bucket.

First, inspect the data that you plan to load. Each document has a JSON format similar to this example.

JSON

```json
{"id": 1, "user_id": 1, "product_id": 14, "subtotal": 37.65, "tax": 2.07, "total"
{"id": 2, "user_id": 1, "product_id": 123, "subtotal": 110.93, "tax": 6.1, "total
```

© 2026 Ocient, Inc

Inspecting the file with Pandas, you can see this schema with details.

Parquet Schema Description

```
 #   Column      Non-Null Count  Dtype
---  ------      --------------  -----
 0   id          18760 non-null  int64
 1   user_id     18760 non-null  int64
 2   product_id  18760 non-null  int64
 3   subtotal    18760 non-null  float64
 4   tax         18760 non-null  float64
 5   total       18760 non-null  float64
 6   discount    1915 non-null   float64
 7   created_at  18760 non-null  datetime64[ns, UTC]
 8   quantity    18760 non-null  int64
```

In this case, Ocient automatically transforms the data to the target columns using some sensible conventions. In other cases, loads require some transformation. Most transformations are identical to functions that already exist in the SQL syntax of the Ocient System.

Prior to creating a pipeline, you can use the `PREVIEW PIPELINE` SQL statement to create your pipeline iteratively. This statement returns a result set that shows the final values that would be loaded but does not load the data into the target table.

Preview the `orders_pipeline` pipeline for the `orders` data set from your database connection prompt. Use the S3 data source with endpoint `https://s3.us-east-1.amazonaws.com`, bucket `ocient-docs`, and filter `metabase_samples/parquet/orders.parquet`. Specify the `parquet` format. Load the data into the `public.orders` table. The `SELECT` part of the SQL statement maps the fields in the Parquet file to the target columns in the created table. In this example, limit the result set to the first five records in the data source.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
PREVIEW PIPELINE orders_pipeline
SOURCE
    S3
        ENDPOINT 'https://s3.us-east-1.amazonaws.com'
        BUCKET 'ocient-docs'
        FILTER 'metabase_samples/parquet/orders.parquet'
    LIMIT 5
EXTRACT
    FORMAT parquet
INTO public.orders
SELECT
    $id as id,
    $user_id as user_id,
    $product_id as product_id,
    $subtotal as subtotal,
    $tax as tax,
    $total as total,
    $discount as discount,
    $created_at as created_at,
    $quantity as quantity;
```

*Output*

SQL

```
id          user_id     product_id subtotal              tax                   tota
-------------------------------------------------------------------------------
1           1           14         37.65                 2.07                  39.7
8           1           123        110.93                6.1                   117.
8           1           105        52.72                 2.9                   49.2
8           1           94         109.22                6.01                  115.
8           1           132        127.88                7.03                  134.

Fetched 5 rows
```

With this preview, you can confirm that the results of the pipeline match your requirements. If there is an issue, you can update the statement and run the `PREVIEW PIPELINE` statement again until it meets your needs.

Next, create the pipeline named `orders_pipeline` for the `orders` data set from your database connection prompt. The pipeline has three main sections:

- `SOURCE` — Loads data from S3. Set the S3 endpoint, bucket name, and filter for the Parquet files.
- `EXTRACT` — Sets the format to Parquet.
- `INTO ... SELECT` — Targets the `public.orders` table and selects the chosen fields from the Parquet records. In this case, all data is available at the top level of the Parquet records, so the example references the fields by the attribute name (e.g., `$id`, `$user_id`, etc.). For nested data, reference the nested fields using dot notation (e.g., `$order.user.first_name`). Each field maps to a target column using the `as` syntax.

SQL

```
CREATE PIPELINE orders_pipeline
SOURCE
    S3
        ENDPOINT 'https://s3.us-east-1.amazonaws.com'
        BUCKET 'ocient-docs'
        FILTER 'metabase_samples/parquet/orders.parquet'
EXTRACT
    FORMAT parquet
INTO public.orders
SELECT
    $id as id,
    $user_id as user_id,
    $product_id as product_id,
    $subtotal as subtotal,
    $tax as tax,
    $total as total,
    $discount as discount,
    $created_at as created_at,
    $quantity as quantity;
```

After you successfully create this pipeline, execute the `START PIPELINE` SQL statement to start the load.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

```sql
START PIPELINE orders_pipeline;
```

## Step 4: Observe the Load Progress

With your pipeline running, data begins to load immediately from the S3 files that you defined. If there are many files in each file group, the load process first sorts the files into batches, partitions them for parallel processing, and assigns them to Loader Nodes.

You can check the pipeline status and progress by querying the `information_schema.pipeline_status` system catalog table or executing the `SHOW PIPELINE_STATUS` SQL statement.

```sql
SHOW PIPELINE_STATUS;
```

*Output*

```sql
database_name         pipeline_name       table_names          status      status
-------------------------------------------------------------------------------
metabase              orders_pipeline     ["public.orders"]    RUNNING     Starte
```

After the status of the pipeline changes to `COMPLETED`, all data is available in the target table.

After a few seconds, the data is available for query in the `public.orders` table.

```sql
SELECT COUNT(*) FROM public.orders;
```

*Output*

SQL

```
count(*)
--------------------
18760
```

You can drop the pipeline with the `DROP PIPELINE orders_pipeline;` SQL statement. Execution of this statement leaves the data in your target table, but removes metadata about the pipeline execution from the system.

# Data Pipeline Load of JSON Data from HDFS

Load JSON data from HDFS into the Ocient System using a data pipeline. Preview the data load, execute the pipeline, and monitor its progress.

The data pipeline functionality enables the loading of data from Apache® Hadoop® Distributed File System (HDFS). You can load various file types stored in HDFS into the Ocient® System.

The Ocient System uses data pipelines to transform each document into rows in one or more different tables. The loading and transformation capabilities use a simple SQL-like syntax for transforming data. This tutorial guides you through a simple example of loading data in the JSON format.

## HDFS Advanced Source Options

Besides the specified options in the **HDFS Source Options** section, you can also specify these options that are available for file system sources:

- COMPRESSION_METHOD
- START_FILENAME
- END_FILENAME
- START_CREATED_TIMESTAMP
- END_CREATED_TIMESTAMP
- START_MODIFIED_TIMESTAMP
- END_MODIFIED_TIMESTAMP
- SORT_BY
- SORT_DIRECTION
- SORT_REWRITE

For Kerberos authentication, you can also specify these options that are available only for HDFS sources:

- PRINCIPAL

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- KEYTAB_FILE
- TOKEN
- TOKEN_FILE
- RENEW_INTERVAL

For details, see **Kerberos Authentication for HDFS Sources**.

For the `CONFIG` source option, the most useful properties are the ones with the `dfs.client` prefix. For the full property reference, see **HDFS Default** and **Core Default**. Only properties that affect client connections and read operations apply to data pipeline loading. This table describes some common properties.

| Property Name | Property Description |
|---|---|
| `dfs.client.use.datanode.hostname` | Set this property to `true` when you have datanodes and namenodes in the HDFS cluster configured to connect to each other using local IP addresses, but loading occurs externally and requires externally valid hostnames instead. The default value is `false`. |
| `dfs.client.retry.max.attempts` | Configure to change the number of times the loading process retries network requests to namenodes before throwing an error. You can increase this value when network connections are unstable. The default value is 10. |
| `dfs.client.socket-timeout` | Configure to change the timeout (in milliseconds) for all sockets used internally in HDFS loading. You can increase this value when network connections are unstable. The default value is 60000 (60 seconds). |

# Kerberos Authentication for HDFS Sources

HDFS sources support Kerberos authentication with these two methods:

- Keytab file — Specify the `PRINCIPAL` and `KEYTAB_FILE` options.
- Delegation token — Specify the `TOKEN` or `TOKEN_FILE` option and, optionally, the `RENEW_INTERVAL` option.

You can specify only one authentication method for each data pipeline. When you create a data pipeline that specifies Kerberos authentication, the Ocient System authenticates to the HDFS cluster during pipeline compilation. If authentication fails, the `CREATE PIPELINE` SQL statement fails.

In most cases, you must also specify the `dfs.namenode.kerberos.principal` and `dfs.data.transfer.protection` configuration properties in the `CONFIG` option so that the loading process can identify the Kerberos principal of the namenode server.

HDFS only supports one Key Distribution Center (KDC) path for each JVM®. Therefore, the KDC path affects all HDFS pipelines within the same system instance. If multiple HDFS pipelines are running, they must share the `krb5.conf` file by listing the principals and realms in it, or you must run them sequentially.

A valid Kerberos configuration file ( `krb5.conf` ) must exist on all Loader Nodes regardless of the authentication method. For help locating the file, see **Locating the krb5.conf Configuration File**. If you do not configure the file location, the system searches the default operating system locations, such as the `/etc/krb5.conf` file on Linux®. To specify a different file location, or to refresh the file after you update its contents, set the `streamloader.extractorEngineParameters.configurationOption.kerberosConfig` configuration setting. This setting affects all data pipelines that run on the Loader Node. For details, see **Configuration Settings for Data Pipelines**.

This example sets the Kerberos configuration file location to the `/etc/krb5.conf` file.

SQL

```
ALTER SYSTEM ALTER CONFIG SET
'streamloader.extractorEngineParameters.configurationOption.kerberosConfig'
'/etc/krb5.conf';
```

All HDFS data pipelines that run concurrently on the same Loader Node share the same Kerberos configuration file. Include the principals and realms for all data pipelines in that file.

Keytab file authentication is the most reliable method. The loading process requests new credentials from the key distribution center (KDC) and automatically logs in again as needed during the load.

With delegation token authentication, the loading process renews the token at the frequency that the `RENEW_INTERVAL` option specifies. The KDC cannot renew a token after the token reaches the renewal lifetime ( `renew_lifetime` ) that you configure in the Kerberos configuration. If the credentials expire before the load finishes, such as during a long-running or continuous data pipeline, the pipeline fails, and the load cannot progress

with the expired credentials. For these cases, use keytab file authentication instead. To resume a failed load with a new delegation token, update the token using the **ALTER PIPELINE** SQL statement and restart the pipeline.

For examples, see “Load Data from HDFS with Kerberos Keytab Authentication” and “Load Data from HDFS with Kerberos Delegation Token Authentication” on the **Data Pipelines** reference page.

## HDFS Loading Example

Follow these steps to load JSON data from an HDFS source into the Ocient System.

### Step 1: Create a New Database

Connect to a SQL Node using the **Commands Supported by the Ocient JDBC CLI Program**. Then, execute the `CREATE DATABASE` SQL statement to create the `geo` database.

SQL

```sql
CREATE DATABASE geo;
```

### Step 2: Create a New Table in the Database

Create the `locations` table in the `public` schema to store location data with a name, zip code, and a point with latitude and longitude:

- `name` — Location name as a not nullable string
- `zipcode` — Zip code as an integer
- `location` — Location latitude and longitude as a point

SQL

```sql
CREATE TABLE public.locations (
    name VARCHAR(255) NOT NULL,
    zipcode INT NOT NULL,
    location POINT
);
```

## Step 3: Preview and Create a Data Pipeline

Preview the `locations` data pipeline to load JSON data from HDFS. This data pipeline uses the HDFS endpoint `hdfs-namenode:9000`, which consists of the namenode and port number, and the `/locations/2026/**/*.json` filter to load data from JSON files. The pipeline selects the name, zip code, and point data. For the point data construction, see **ST_POINT**.

SQL

```
PREVIEW PIPELINE locations
  SOURCE hdfs
    ENDPOINT 'hdfs-namenode:9000'
    FILTER '/locations/2026/**/*.json'
  EXTRACT
    FORMAT json
  INTO locations
  SELECT
    $name AS name,
    $zipcode AS zipcode,
    ST_POINT($longitude, $latitude) AS location;
```

Create the `locations` data pipeline to load JSON data from HDFS.

SQL

```
CREATE PIPELINE locations
  SOURCE hdfs
    ENDPOINT 'hdfs-namenode:9000'
    FILTER '/locations/2026/**/*.json'
  EXTRACT
    FORMAT json
  INTO locations
  SELECT
    $name AS name,
    $zipcode AS zipcode,
    ST_POINT($longitude, $latitude) AS location;
```

After you successfully create the `locations` pipeline, execute the `START PIPELINE` SQL statement to start the data pipeline.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

```SQL
START PIPELINE orders_pipeline;
```

## Step 4: Observe the Load Progress

With your pipeline running, data begins to load immediately from the JSON files. If there are many files in each file group, the load process first sorts the files into batches, partitions them for parallel processing, and assigns them to Loader Nodes.

You can check the pipeline status and progress by querying the `information_schema.pipeline_status` system catalog table or executing the `SHOW PIPELINE_STATUS` SQL statement.

```SQL
SHOW PIPELINE_STATUS;
```

Output

```SQL
database_name         pipeline_name       table_names              status      statu
-------------------------------------------------------------------------------------
geo                   locations           ["public.locations"]     RUNNING     Start
```

After the status of the pipeline changes to `COMPLETED`, all data is available in the target table.

After a few seconds, the data is available for query in the `public.locations` table.

```SQL
SELECT COUNT(*) FROM public.locations;
```

*Output*

SQL

```
count(*)
--------------------
25605
```

You can drop the pipeline with the `DROP PIPELINE locations;` SQL statement. Execution of this statement leaves the data in your target table, but removes metadata about the pipeline execution from the system.

# Data Types for Data Pipelines

Reference for how Ocient data types map to source data formats during data pipeline loads, including conversions, NULL handling, and supported coercions.

## Source Fields

When you load data using a data pipeline, you reference extracted data using a special syntax named a source field reference. These source field references can behave differently depending on the data format. It is important to understand how to reference source field data and also how Ocient® assigns the type of data you reference.

### Source Field References

You reference source fields in a pipeline using a named reference such as `$my_field` or a numeric field reference such as `$1`. For some data formats like JSON and Apache® Parquet™, Ocient supports nested data access such as `$my_field.sub_field`.

Learn more about what source field references are supported for each data format in **Data Formats for Data Pipelines**.

### Source Field Data Types

The Ocient System treats references to source fields (e.g., `$my_field`) differently depending on the data format `FORMAT` specified in the data pipeline.

#### Text-Based Data Formats

For text-based formats such as `DELIMITED` and `JSON`, the Ocient System treats source fields as `VARCHAR`. For `JSON` data, the system treats source fields strictly as `VARCHAR` data even if the field value is represented logically in JSON as Boolean, integer, NULL, or double. Learn more about text-based formats in **Load JSON Data** and **Load Delimited and CSV Data**.

#### Binary-Based Data Format

For the binary-based format `BINARY`, Ocient treats source fields as the `BINARY` data type. Learn more about binary formats in **Load Binary Data**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### Parquet-Based Data Format

For the Parquet-based format `PARQUET`, Ocient encodes information about the data type of the fields during the load.

## Supported Data Types

The data pipeline functionality supports all column data types.

> `ST_POINT` is not supported in a three-coordinate format.

When you load data into a column type, in many cases, Ocient automatically casts the source data to the target column. However, in some cases, you might need to cast data to the target column type explicitly. Learn more about supported casting functions in **Scalar Transformation Functions and Casting**.

## Automatic Conversion and Casting

Loading pipelines apply automatic casting to the final values of your transformations and source fields where the data type does not match the target column type. The casting function that the Ocient System applies varies based on the SQL type of the data that results from your transformation and the SQL type of the target column.

The system applies casting automatically in cases to resolve conflicts between data types:

- Promotion of a type to expand to a wider data type (e.g., `SMALLINT` to `BIGINT`)
- Implicit casting from one family of data type to another (e.g., `VARCHAR` to `TIMESTAMP`)
    - Ocient supports implicit casting of all simple data types to `VARCHAR`.

> Auto-casting in Parquet does not support the automatic conversion to `VARCHAR` columns. You must explicitly cast data to the `CHAR` data type when you convert Parquet data that is not string data to a `VARCHAR` column or `VARCHAR` function argument.

Automatic casting does not apply in some situations where data loss might occur:

- Implicit downcasting to a narrower data type (e.g., `BIGINT` to `SMALLINT`)

Where automatic casting is not supported, you can explicitly cast data or use built-in transformation functions according to your requirements. See **Transform Data in Data Pipelines** for more details.

## Implicit Casting Support List

### VARCHAR Source Data

The Ocient System treats the source field reference from `JSON` and `DELIMITED` formatted data as `VARCHAR` regardless of the logical type in the source.

Ocient supports the implicit casting of `VARCHAR` to all data types.

### BINARY Source Data

The system treats the source field reference from `BINARY`-formatted data as raw bytes with automatic casting functions tailored to the `BINARY` data type.

Ocient supports implicit casting of `BINARY` to:

- `TINYINT`, `SMALLINT`, `INT`, `BIGINT`
- `FLOAT`, `DOUBLE`
- `TIMESTAMP`, `DATE`, `TIME` (as `VARCHAR` data)

> For `BINARY` or `VARCHAR` to `BOOL`:
>
> - You can represent `true` as: `'t', 'true', 'yes', '1', 'y', 'on'`
> - You can represent `false` as: `'f', 'false', 'no', '0', 'n', 'off'`
>
> The system matches these values regardless of case. Any other value causes the record to fail with a transformation error.

> For `BINARY` or `VARCHAR` to `TIMESTAMP`, `DATE`, and `TIME`, the automatic casting assumes that the character data has the format:
>
> - `TIMESTAMP` — `YYYY-MM-DD HH:mm:ss[.SSSSSSSSS]`
> - `DATE` — `YYYY-MM-DD`
> - `TIME` — `HH:mm:ss`

### Other Implicit Casts or Downcasts

The system also supports some other implicit casts that are not type promotions:

- `TIMESTAMP` data implicitly downcasts to `DATE` and `TIME` columns, truncating the unused portion.
  - ℹ️This option is available in version 25 or later.
- The system implicitly casts all simple types to `VARCHAR` columns except:
  - `HASH` or `BINARY`
  - `DECIMAL`
  - `IP` or `IPV4`

For geospatial data types, see **Load Geospatial Data in Data Pipelines**.

## Data Type Promotion List

The data type promotion list describes how the Ocient System can automatically promote the specified type to a target column type. The system achieves the promotion using standard casting functions (e.g., `BIGINT(SMALLINT)`). See **Implicit Casting Support List** for implicit casting, for example casting to `VARCHAR`.

| Source Data Type | Automatic Casting Precedence for Target Column Type |
|---|---|
| `BYTE` or `TINYINT` | `BYTE` `TINYINT` `SMALLINT` `INT` `BIGINT` `FLOAT` `DOUBLE` |
| `SMALLINT` | `SMALLINT` `INT` `BIGINT` `FLOAT` `DOUBLE` |
| `INT` | `INT` `BIGINT` `FLOAT` `DOUBLE` |
| `BIGINT` | `BIGINT` `DOUBLE` `TIMESTAMP` `TIME` |
| `FLOAT` | `FLOAT` `DOUBLE` |
| `DOUBLE` | `DOUBLE` |
| `DECIMAL` | `DECIMAL` |
| `BOOL` | `BOOLEAN` |
| `UUID` | `UUID` |

| Source Data Type | Automatic Casting Precedence for Target Column Type |
|---|---|
| `DATE` | `DATE` `TIMESTAMP` |
| `TIME` | `TIME` |
| `TIMESTAMP` | `TIMESTAMP`<br>See **Implicit Casting Support List** for supported downcasting. |
| `IPV4` | `IPV4` |
| `IP` | `IP` |
| `BINARY` | `BINARY`<br>See **Implicit Casting Support List** for supported cross-casting. |
| `ARRAY` | `ARRAY` |
| `TUPLE` | `TUPLE` |
| `VARCHAR` | `VARCHAR`<br>See **Implicit Casting Support List** for supported cross-casting. |
| `ST_POINT` | `ST_POINT` , `ST_LINESTRING` , `ST_POLYGON` |
| `ST_LINESTRING` | `ST_LINESTRING` , `ST_POLYGON` |
| `ST_POLYGON` | `ST_POLYGON` |

- `BIGINT` to `TIME` automatic casting assumes a time value in milliseconds.
- `BIGINT` to `TIMESTAMP` automatic casting assumes milliseconds after the epoch. (January 1, 1970 at midnight UTC)
- For complex types, the system applies the type precedence for automatic casting to the elements in the type.
- Automatic casting of integral types to DOUBLE and FLOAT are potentially lossy due to limits in precision of floating point representations.
  - ℹThis option is available in version 25 or later.

The system treats `BYTE` and `TINYINT` aliases identically.

# Data Formats for Data Pipelines

Load JSON, DELIMITED, Avro, Parquet, and other formats into Ocient with data pipelines, including field selectors, type interpretation, and NULL handling.

Loading in Ocient® differs in subtle ways that depend on the data format of the source. Loading runs with a strict interpretation of streaming source with Apache® Kafka® or source data to allow pipelines to achieve maximum performance. For text-based formats like `JSON` and `DELIMITED`, the Ocient System performs no preemptive casting on the data when using a source field selector. For the Kafka streaming source, use the Confluent® Schema Registry with subjects that contain a group of schema versions, which capture the schema changes over time.

For example, with the JSON string `{ "my_field": 1234 }`, the selector `$my_field` returns the string `"1234"` not the integer `1234`.

When you use transformation functions, keep in mind that the Ocient System treats all data in the `JSON` and `DELIMITED` formats as text data.

While the Ocient System sends data you select to a final target column, the system automatically casts the data in the final step to ensure that the data is compatible with the target column type. See **Data Types for Data Pipelines** for supported automatic conversion rules.

Format-specific differences also appear in the pipelines.

## Load ASN.1 Data

You can load data in ASN.1 (Abstract Syntax Notation One) format from binary-encoded ASN.1 files using DER-encoded or BER-encoded files. ASN.1 provides a flexible, schema-driven format commonly used in telecommunications, security, and standardized protocols. This format allows you to extract structured records and map them to relational tables using SQL.

The Ocient System requires `.ber` and `.der` files to contain one or more concatenated DER-encoded or BER-encoded values with the specified record type. The system decodes each record independently and maps it into a record.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## ASN.1 Type Mapping

The system automatically converts all decoded ASN.1 fields to their JSON-equivalent representations.

> The ASN.1 schema must consistently use implicit or explicit tagging. You must specify clear tagging so the system can resolve field names during extraction.

| ASN.1 Type | JSON Mapping | Description |
|---|---|---|
| `INTEGER` | Number | The number, specified as an integer.<br><br>Example: `5` |
| `BOOLEAN` | Boolean | The logical value, specified as a Boolean.<br><br>Example: `true` |
| `VisibleString` | String | The ASN.1 type assumes UTF-8 encoding.<br><br>Example: `"Data Analyst"` |
| `IA5String` | String | The International Alphabet number 5 (IA5) includes most of the ASCII alphabet but can contain other characters.<br><br>Example: `"ABCD"` |
| `UTF8String` | String | The ASN.1 type assumes UTF-8 encoding.<br><br>Example: `"abcd"` |
| `OCTET STRING` | Hexadecimal string | The hexadecimal string has the prefix `0x`.<br><br>Example: `"0x4fa2"` |
| `BIT STRING` | Hexadecimal string | The hexadecimal string with preserved bit alignment has the prefix `0x`.<br><br>Example: `"011110"` |
| `OBJECT IDENTIFIER` | String | The unique identifier for an object using dotted representation.<br><br>Example: `"1.2.840.113549"` |
| `ENUMERATED` | Number or symbolic string | The enumerated string, if the data resolves into a list of named items.<br><br>Example: `"red"` |

© 2026 Ocient, Inc

| ASN.1 Type | JSON Mapping | Description |
| --- | --- | --- |
| `ANY` | Hexadecimal string | The hexadecimal string with raw encoded bytes of the embedded value.<br><br>Example: `"0x616263"` |
| `SEQUENCE`, `SET` | JSON object | Object with fields that are accessible by their component names.<br><br>Example: `WeatherRecord ::= SEQUENCE { temperature INTEGER, humidity INTEGER, cloudy BOOLEAN }` |
| `SEQUENCE OF`, `SET OF` | JSON array | Array of objects where the elements are fully decoded.<br><br>Example: `WeatherEvents ::= SEQUENCE OF WeatherRecord` |
| `CHOICE` | JSON object | An object with fields of any type. Identify the active alternative by the key.<br><br>Example: `WeatherReport ::= CHOICE { sunny SEQUENCE { uv\_index INTEGER }, rainy SEQUENCE { precipitation INTEGER } }` |
| `DATE` | String | Date in the format `"yyyyMMdd"`. You must explicitly declare the date, or the system must infer it using tagging.<br><br>Example: `"20240518"` |
| `TIME` | String | Time in the format `"HHmmss"`.<br><br>Example: `"113056"` |
| `DATE-TIME` | String | Date and time in the format `"yyMMddHHmmss'Z'"`. This format supports only UTC. You must include `'Z'` as a literal.<br><br>Example: `"250920101508'Z'"` |

To access fields, use dot notation for access: `$sequence.fieldName`. For arrays (such as `SEQUENCE OF`), use bracket notation: `$sequenceOf[].fieldElement`.

Default values and optional fields follow standard ASN.1 rules. If you omit a field, the system evaluates it as `NULL`.

## ASN.1 Loading Example

Assume you have the `personnel_records.asn` file in the ASN.1 data format. The file contains the definition of a personnel record `Example.PersonnelRecord`. The ASN.1 file contains data for the personnel record, child, personnel name, employee number of the personnel, and the date.

Text

```
Example DEFINITIONS IMPLICIT TAGS ::=
BEGIN
    PersonnelRecord ::= [APPLICATION 0] SET {
        name         [0] Name,
        title        [1] VisibleString,
        number       [2] EmployeeNumber,
        dateOfHire   [3] Date,
        nameOfSpouse [4] Name,
        children     [5] SEQUENCE OF ChildInformation DEFAULT {}
    }
    ChildInformation ::= SET {
        name        [0] Name,
        dateOfBirth [1] Date
    }
    Name ::= [APPLICATION 1] SEQUENCE {
        givenName  [0] VisibleString,
        initial    [1] VisibleString,
        familyName [2] VisibleString
    }
    EmployeeNumber ::= [APPLICATION 2] INTEGER
    Date ::= [APPLICATION 3] VisibleString
END
```

Create a table to contain the personnel record. The table contains a subset of the data:

- `first_name` — First name
- `initial` — Initial of the middle name
- `family_name` — Last name
- `title` — Job title
- `number` — Employee number
- `date_of_hire` — Hire date

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```sql
CREATE TABLE personnel_records(
    first_name VARCHAR NOT NULL,
    initial VARCHAR NOT NULL,
    family_name VARCHAR NOT NULL,
    title VARCHAR NOT NULL,
    number BIGINT NOT NULL,
    date_of_hire DATE NOT NULL
);
```

Create the data pipeline `personnel_pipeline` to load the personnel record into the `personnel_records` table using an Amazon® Web Services™ (AWS™) S3 bucket. Specify the bucket, endpoint, access key identifier, secret access key, and filter options to find the ASN.1 DER-encoded file `personnel_records.der` in the specified file path. Use the URL file path `http://cos/filepath/asn1/personnel_records.asn` and record type `Example.PersonnelRecord`. Access the `name` sequence using dot notation for the first name, middle initial, and last name fields. The pipeline definition transforms the hire date to the `'yyyyMMdd'` format.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE PIPELINE personnel_pipeline
    SOURCE S3
        BUCKET 'misc'
        ENDPOINT 'http://cos'
        ACCESS_KEY_ID ''
        SECRET_ACCESS_KEY ''
        FILTER_GLOB 'user/asn1/personnel_records.der'
    EXTRACT
        FORMAT 'asn.1'
        SCHEMA {
            URL 'http://cos/filepath/asn1/personnel_records.asn'
            RECORD_TYPE 'Example.PersonnelRecord'
        }
INTO personnel_records
SELECT
    $name.givenName AS first_name,
    $name.initial as initial,
    $name.familyName as family_name,
    $title as title,
    $number as number,
    TO_DATE($dateOfHire, 'yyyyMMdd') as date_of_hire;
```

# Load Avro Data

The Ocient System enables you to load data in the Apache® Avro™ format. You can use a streaming source with a file-based source only. Load an inline schema definition or use a schema configuration. Use a schema inference from files with embedded schemas.

Field selectors in Avro follow the same format as selectors in JSON and Apache® Parquet™ formats.

ⓘ The Ocient System treats Avro selectors as lowercase. To use case-sensitive selectors, you must enclose the selector in double quotation marks. For example, `$"testSelector"`.

## Inline Schema

Specify a JSON string in the Avro schema format in the `INLINE` option of the schema definition of the `CREATE PIPELINE` SQL statement.

Inline schemas assume that all records follow the defined schema exactly. These schemas do not support schema evolution.

For Kafka messages, use the `SCHEMA_REGISTRY_ID_LOCATION` option to denote whether there is an embedded schema identifier. For inline schemas, the `'none'` value indicates that no embedded schema identifier is present.

## Schema Inference from a File

The system can infer the schema from a file that has embedded schemas. The file is a named object container file. Use the `INFER_FROM` option in the `CREATE PIPELINE` SQL statement to specify sampling one file.

## Schema Registry

For loading from a Kafka streaming source, use the schema configuration with the `SUBJECT` option in the `CREATE PIPELINE` SQL statement to specify the name of the subject for the data pipeline. The default value is `<topic name>-value`, where `<topic name>` is the name of the Kafka topic. The Ocient System follows the schema registry configuration from the Confluent platform.

## Schema Evolution

When you create a data pipeline, the pipeline has a fixed target schema (specified by the `SELECT` clause). Individual files might have different schemas. The target schema must be backward-transitive compatible with the other schemas. Individual files or Kafka messages might have different schemas.

If the other schemas change, the system automatically attempts to fit data into the target schema. In this case, the other schemas must be forward compatible with the target schema. The system ignores changes to any unused fields from the target schema.

To manually change the schema, you must first stop the execution of the data pipeline by using the `STOP PIPELINE` SQL statement. Then, use the `ALTER PIPELINE` SQL statement to modify the schema. You can add a field, remove a field, or change the precision of a data type. For details, see the **ALTER PIPELINE** SQL statement.

> Multiple schemas impact the performance of the data pipeline execution. For best performance, use a single schema for all data.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Avro Type Mapping

The Ocient System converts these Avro data types to Ocient SQL types. This table shows the respective conversions.

| Avro Type | Ocient SQL Type |
|---|---|
| `null` | `NULL` |
| `boolean` | `BOOLEAN` |
| `int` | `INT` |
| `long` | `BIGINT` |
| `float` | `FLOAT` |
| `double` | `DOUBLE` |
| `bytes` | `VARBINARY` |
| `string` | `VARCHAR` |
| `record` | Select subfields of the record using the standard pipeline selector syntax, e.g., `$myrecord.subfield`. |
| `enum` | `VARCHAR` |
| `array` | `ARRAY` |
| `map` | Select entries of the map using the key with the standard pipeline selector syntax, e.g., `$mymap.key`. |
| `fixed` | `HASH` |
| `decimal` | `DECIMAL` |
| `big-decimal` | `DECIMAL` |
| `uuid` | `UUID` |
| `date` | `DATE` |
| `time-*` | `TIME` |
| `timestamp-*` | `TIMESTAMP` |
| `local-timestamp-*` | `TIMESTAMP` |
| `duration` | The system converts duration to a record with integer subfields for `months`, `days`, and `milliseconds`. |
| `union` | The system converts a union between `NULL` and another type to a nullable version of that type. In contrast, the system converts a union containing |

| Avro Type | Ocient SQL Type |
| --- | --- |
| | multiple non-`NULL` types to a string. |

## Avro Loading Examples

Create the `users` table with these columns:

- `id` — Universally Unique IDentifier (UUID) of the user
- `firstname` — First name of the user
- `lastname` — Last name of the user
- `birthyear` — Year of birth
- `groups` — List of groups where the user belongs

SQL

```
CREATE TABLE users(
    id          UUID NOT NULL,
    firstname   VARCHAR(255) NOT NULL,
    lastname    VARCHAR(255) NOT NULL,
    birthyear   INT,
    groups      VARCHAR(255)[] NOT NULL DEFAULT 'char[]'
);
```

These examples use this table as the target table for the load.

### Load Avro Data from Files

Assume you have user data in Avro format in multiple files in the `/data/users` directory. Create the `users_pipeline` data pipeline for the Avro files `*.avro` containing user data. The schema configuration instructs the system to infer from one file using the `INFER_FROM` option. Access the array of strings for the `groups` column.

SQL

```
CREATE PIPELINE users_pipeline
SOURCE filesystem
    FILTER '/data/users/*.avro'
EXTRACT
    FORMAT avro
    SCHEMA {
        INFER_FROM 'sample_file'
    }
INTO users
SELECT
    $id         AS id,
    $firstname  AS firstname,
    $lastname   AS lastname,
    $birthyear  AS birthyear,
    $groups[]   AS groups;
```

### Load Avro Data from an Inline Schema Definition

Assume you have user data in Avro format in multiple files in the `/data/users` directory. Create the `users_pipeline` data pipeline for the Avro files `*.avro` containing user data. The schema configuration instructs the system to use an inline schema definition with the `INLINE` option. Access the array of strings for the `groups` column.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE PIPELINE users_pipeline
SOURCE filesystem
    FILTER '/data/users/*.avro'
EXTRACT
    FORMAT avro
    SCHEMA {
        INLINE '{
            "type": "record",
            "name": "User",
            "namespace": "test.users",
            "fields": [
                { "name": "id",        "type": { "type": "string", "logicalType": "
                { "name": "firstname", "type": "string" },
                { "name": "lastname",  "type": "string" },
                { "name": "birthyear", "type": ["null","int"], "default": null },
                { "name": "groups",    "type": { "type": "array", "items": "string"
            ]
        }'
    }
INTO users
SELECT
    $id         AS id,
    $firstname  AS firstname,
    $lastname   AS lastname,
    $birthyear  AS birthyear,
    $groups[]   AS groups;
```

### Load Avro Data Using a Kafka Schema Registry Configuration

Assume you have user data in Avro format in a Kafka topic. Create the `users_pipeline` data pipeline for the user data. The schema registry configuration instructs the system to access the subject `'users-value'` at the registry location `'value'` using the registry URL `'https://schema-registry.company.com'`. The configuration specifies the access credentials using the `CONFIG` option:

- Credentials source
- User authentication that includes the username and password
- Location of the truststore

- Password for the truststore

Access the array of strings for the `groups` column.

SQL

```
CREATE PIPELINE users_pipeline
SOURCE
    KAFKA
        BOOTSTRAP_SERVERS '192.168.0.1:9092'
        TOPIC 'users'
EXTRACT
    FORMAT avro
    SCHEMA {
        SUBJECT 'users-value'
        SCHEMA_REGISTRY_ID_LOCATION 'value'
        URL 'https://schema-registry.company.com'
        CONFIG '{
            "basic.auth.credentials.source": "USER_INFO",
            "basic.auth.user.info": "sr_user:sr_password",
            "ssl.truststore.location": "/etc/ssl/truststore.jks",
            "ssl.truststore.password": "testpassword"
        }'
    }
INTO users
SELECT
    $id         AS id,
    $firstname  AS firstname,
    $lastname   AS lastname,
    $birthyear  AS birthyear,
    $groups[]   AS groups;
```

For details about the schema registry configuration, see the **Confluent Documentation**.

## Load Binary Data

The Ocient System loads the binary data format using a fixed record length to split a binary stream into chunks that represent records. Each record is available in the `SELECT` portion of a pipeline definition using a special binary extract syntax `$"[5,8]"`. This operates similarly to a substring function, beginning at byte `5` and taking `8` bytes from that location. The starting index is a 1-based offset, consistent with other SQL arrays and

offsets. You can use this syntax to select specific bytes within a record to parse together as a unit.

## Binary Selector

| Selector | Description | Examples |
|---|---|---|
| `$"[<start_index>, <length_in_bytes>]"` | **Extract Bytes** — Extracts the bytes beginning at the `<start_index>` and returning `<length_in_bytes>` total bytes to extract from the start index. `<start_index>` is 1-based. | `abc123.45xyz` `$"[4,6]" -> "123.45"` This example illustrates the operation using ascii characters, but the Binary Selector returns BINARY data, byte arrays, that may be used in special ways by fixed width processing functions described in **Binary Data Transformations**. |

### Example

The Binary Selector takes eight bytes starting at offset 11 on the fixed-width binary record. Consistent with SQL functions in the Ocient System, the first argument value `11` is the 1-based offset into the byte array.

SQL

```
$"[11, 8]"
```

The Binary Selector returns `BINARY` data, not `VARCHAR`.

Special `BINARY` transformation functions can operate on this `BINARY` data. However, if you cast data to the `VARCHAR` type by using `CHAR()`, then functions like `INT` operate on this data as `VARCHAR` data, not binary data.

When you load binary data into `VARCHAR` columns, the Ocient System automatically converts from binary to character data using the configured `CHARSET_NAME` before final loading.

The Ocient System supports special transformation functions that operate uniquely on binary data. With these functions, you can convert binary representations from mainframe systems such as packed decimals, zoned decimals, big and little endian integers (signed and unsigned), and floating point values. For more details, see **Binary Data Transformation Functions**.

© 2026 Ocient, Inc Ocient Proprietary and Confidential

For a complete list of supported options for `DELIMITED` and `CSV` data formats, see **Binary Extract Options**.

## Binary Loading Example

If each record in your fixed-width binary schema includes these fields, you can use the `SUBSTRING` function and the transforms shown in this example.

| Column | Start Index | Record Length | Source Data Type | Ocient Target Data Type |
|---|---|---|---|---|
| first_name | 1 | 20 | Character | VARCHAR |
| last_name | 21 | 20 | Character | VARCHAR |
| age | 41 | 4 | Big Endian signed 4-byte integer | INT |
| total_spent | 45 | 10 | Packed Decimal | DECIMAL(10,2) |
| user_id | 55 | 8 | Little Endian unsigned 8-byte long | BIGINT |

Each record includes 62 bytes, so the record length `RECORD_LENGTH` is 62. The encoding of this file is CP500 instead of the default IBM1047 code page. The `CREATE PIPELINE` SQL statement specifies this encoding.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE PIPELINE binary_users_pipeline
SOURCE
    S3 ...
FORMAT
    BINARY
    RECORD_LENGTH 62
    CHARSET_NAME 'cp500'
INTO public.users
SELECT
    $"[1, 20]" as first_name,
    $"[21, 20]" as last_name,
    INT($"[41, 4]") as age,
    DECIMAL($"[45, 10]", 'packed', 2) as total_spent,
    BIGINT($"[55, 8]", 'unsigned', 'little') as user_id;
```

This SQL statement:

- Uses the `BINARY SELECTOR` to extract names and load them into the respective columns. The Ocient System automatically decodes the values using `cp500` and loads them into a `VARCHAR` column. An explicit cast such as `CHAR($"[1, 20]") as first_name` works equivalently.
- Indicates the extraction of four bytes that represent age from bytes 41-44. The statement instructs the casting of these bytes as an integer `INT`. This function uses the default endianness (big) and treats the bytes as signed. Unsigned values can overflow target columns because integral types are all signed.
- Extracts the 10 bytes for `total_spent` using the `BINARY SELECTOR`, and converts the values using the `packed` decimal option for the `DECIMAL` cast. The casting requires specifying the number of decimal points in the source data. In this case, there are two decimal points, which match the number in the target column.
- Extracts the eight bytes that represent `user_id` using the `BINARY SELECTOR` and casts these bytes to a `BIGINT` while interpreting the bytes as unsigned with the little endian representation.

## Load Delimited and CSV Data

When you load data from delimited or CSV files, the Ocient System tokenizes the data during loading. The system detects records and fields in the input data during pipeline execution. You can reference fields and use them in combination with transformation functions before the system stores values in the column of a target table.

Files must be located in these allowed directories:

- `/tmp` directory
- The temporary directory you configure using the `streamloader.extractorEngineParameters.tempDir` configuration option (default path is `/var/opt/ocient/tmp`).
- The directory list specified by the `streamloader.extractorEngineParameters.configurationOption.filesystem.access.directories` configuration option (default is an empty list).

Files cannot be located in these blocked directories:

- `/etc`
- `/bin`
- `/sbin`
- `/lib`
- `/lib64`
- `/usr`
- `/boot`
- `/proc`
- `/sys`
- `/run`
- `/root`
- `/var/lib`
- `/var/log`
- `/var/run`
- `/var/cache`

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Referencing fields of the source data for the formats happens by using a field index. The index is a number that follows the dollar sign `$`. To maintain consistency with SQL array semantics, the field indexes start at 1.

Reference the first field of tokenized source records for the `DELIMITED` and `CSV` formats as `$1`.

> ⚠ For the `BINARY` format, `$0` represents the entire record. In this case, you must specify `$0` in combination with the `SUBSTRING` function to extract specific bytes from the source data.

For a complete list of supported options for `DELIMITED` and `CSV` data formats, see **Delimited and CSV Extract Options**.

## Delimited Loading Example

Use this example delimited data.

Text

```
iphone|60607|viewed|502|293.99|[shopping,news]
```

For this example row, this table shows the field references for each value in the row.

| Field Reference | Value |
|---|---|
| $1 | iphone |
| $2 | 60607 |
| $3 | viewed |
| $4 | 502 |
| $5 | 293.99 |
| $6\[] | \[‘shopping’,‘news’] |

To load this data in a pipeline with the `DELIMITED` data format, this `CREATE PIPELINE` statement specifies the `|` character for the field delimiter. This statement loads data into AWS S3. The `SELECT` statement uses fields 1, 2, 3, 5, and 6 of the source data. The statement specifies that the system should not load field 4 to the target table. Field 6 is

an array of data matching the default array settings for delimited data. You can indicate this with the array brackets like `$6[]` to load into a `CHAR[]` typed column.

The outer casting functions in this example are optional and shown for completeness. If they are omitted, the pipeline automatically casts the source fields to the target column type.

SQL

```
CREATE PIPELINE delimited_pipeline
SOURCE s3
    ...
FORMAT delimited
    FIELD_DELIMITERS ['|']
    ...
SELECT
    CHAR($1) as device_model,
    INT($2) as zip,
    INT($3) as amount,
    DOUBLE($5) as price,
    CHAR[]($6[]) as categories;
```

## Load JSON Data

The data pipeline syntax enables the load of JSON data, including nested scalars, arrays, and points `ST_POINT`.

**Strict Loading and Transformations**

When you use transformation functions, remember that the Ocient System treats all data in `JSON` and `DELIMITED` format as text data, not the `logical` data type.

For example, if you specify the JSON string `{ "my_timestamp": 1709208000000 }`, the selector `$my_timestamp` returns the string `"1709208000000"` and not the integer `1709208000000`.

As a result, if you cast this data into a timestamp column, such as `TIMESTAMP($my_timestamp) as created_at`, the Ocient System returns an error. The conversion fails because the cast function assumes you are specifying `TIMESTAMP(VARCHAR)`, which assumes a format like `YYYY-MM-DD HH??ss[.SSSSSSSSS]`.

To correct this issue, cast the value explicitly to make use of the `TIMESTAMP(BIGINT)` function that treats the argument as milliseconds after the epoch as in `TIMESTAMP(BIGINT($my_timestamp)) as created_at`.

© 2026 Ocient, Inc

## Supported JSON Selectors

JSON selectors consist of `$` followed by a dot-separated list of JSON keys. If a key refers to an array, it is followed by a set of brackets `[]` to correspond to its dimensionality. If the square brackets contain an index, like `[1]`, then the selector refers to an array element.

> The Ocient System treats JSON selectors as lowercase. To use case-sensitive selectors, you must enclose the selector in double quotation marks. For example, `$"testSelector"`. With case-sensitive selectors having multiple JSON keys, each key needs double quotation marks. For example, `$"testData"."Responses"."SuccessResponse"`.

For special characters (any identifier that starts with any character other than a letter or contains any character that is not a letter, number, or an underscore) or reserved SQL keywords (such as `SELECT`), you must enclose such selectors in double quotation marks. For example, if you have a JSON document `{ "test-field": 123 }`, then the selector for the query should be `$"test-field"`.

The Ocient System does not support identifiers with a backslash as the last character in the key name.

This table shows the selector and provides its description. The cells in the last column of the table show an example for each selector. First, the cell shows example data in JSON format. Then, the cell shows the use of the selector and its output after the arrow.

| Selector | Description | Examples |
|---|---|---|
| `$a` | **Scalar** — Refers to key `a` at the top of a JSON document, where the value of `a` is a scalar. | `{ "first_name": "Chris" }`<br>`$first_name -> "Chris"` |
| `$a[]` | **Array** — Refers to key `a` at the top of a JSON document, where the value of `a` is a one-dimensional array. | `{ "names": ["Chris", "Joe"] }`<br>`$names[] -> ["Chris","Joe"]` |
| `$a[1]` | **Array Element Selection** — Selects a single element from the array `a` at the top of a JSON document, where the value of `a` is a one-dimensional array. Also works on multi-dimensional arrays. Indexes start at 1. | `{ "names": ["Chris", "Joe"] }`<br>`$names[2] -> "Joe"` |
| `$a[][]` | **Multi-dimensional Array** — Refers to key `a` at the top of a JSON document, where the value of `a` is a two-dimensional array. | `{ "coordinates": [ [87.31, 18.25],[65.22, 19.41]] }`<br>`$coordinates[][] -> [[87.31,18.25],[65.22,19.41]]` |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Selector | Description | Examples |
| --- | --- | --- |
| `$a.b.c` | **Nested Selector** — Drills into the value at key `a`, then value at key `b`, and refers to the value at key `c`, where none of the values are arrays. | `{ "user": { "name": "Chris" } }`<br>`$user.name -> "Chris"` |
| `$a[].b` | **Array Projection** — A projection applies a JSON selector on all elements in an array, returning an array.<br>Array brackets in the notation indicate which items are the arrays.<br>The `a[]` is an array. The `b` selector is applied to each element in the array `a`. | `{`<br>`"users": [`<br>`{`<br>`"name": "Chris",`<br>`"orders": [`<br>`{ "order_id": 1,`<br>`"subtotal": 19.29 },`<br>`{ "order_id": 2,`<br>`"subtotal": 16.71 }`<br>`]`<br>`},`<br>`{`<br>`"name": "Joe",`<br>`"orders": [`<br>`{ "order_id": 3,`<br>`"subtotal": 17.29 },`<br>`{ "order_id": 4,`<br>`"subtotal": 22.49 }`<br>`]`<br>`}`<br>`]`<br>`}`<br>`$users[].name -> ["Chris",`<br>`"Joe"]` |
| `$a.b[].c.d[]` | **Multi-level Array Projection** — Applies selectors to each element in the specified arrays and allows multiple levels of objects and arrays for the selection of an N-dimensional array of values.<br>The values of `b` and `d` are arrays, resulting in two-dimensional arrays. The selector `c.d[]` is projected into the elements in the array `b`. | `{`<br>`"users": [`<br>`{`<br>`"name": "Chris",`<br>`"orders": [`<br>`{ "order_id": 1,`<br>`"subtotal": 19.29 },`<br>`{ "order_id": 2,`<br>`"subtotal": 16.71 }`<br>`]`<br>`},`<br>`{`<br>`"name": "Joe",`<br>`"orders": [`<br>`{ "order_id": 3,`<br>`"subtotal": 17.29 },`<br>`{ "order_id": 4,`<br>`"subtotal": 22.49 }`<br>`]`<br>`}`<br>`]` |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Selector | Description | Examples |
| --- | --- | --- |
| | | `}`<br>`$users[].orders[].order_id ->`<br>`[[1,2],[3,4]]` |
| `$a.b[1].c.d[]` | **Array Slice** — Selects the first element from the array `b` and drills into `c` and then the array `d`. JSON array selectors have an index that starts at 0. | `{`<br>`"users": [`<br>`{`<br>`"name": "Chris",`<br>`"orders": [`<br>`{ "order_id": 1,`<br>`"subtotal": 19.29 },`<br>`{ "order_id": 2,`<br>`"subtotal": 16.71 }`<br>`]`<br>`},`<br>`{`<br>`"name": "Joe",`<br>`"orders": [`<br>`{ "order_id": 3,`<br>`"subtotal": 17.29 },`<br>`{ "order_id": 4,`<br>`"subtotal": 22.49 }`<br>`]`<br>`}`<br>`]`<br>`}`<br>`$users[1].orders[].subtotal ->`<br>`[17.29,22.49]` |
| `$a.{b,c}` | **Tuple Selector** — Selects the values from an object as a tuple. You must cast the values to an appropriate `TUPLE` data type. | `{ "user": { "first_name":`<br>`"John", "last_name": "Doe" }}`<br>`$user.{first_name,last_name} -`<br>`> <<"John","Doe">>` |
| `$a[].{b,c}` | **Array of Tuples Selector** — Selects the values from an array of objects as an array of tuples. You must cast the values to an appropriate `TUPLE[]` data type. | `{ "users": [ { "first_name":`<br>`"John", "last_name": "Doe" },`<br>`{ "first_name": "Steve",`<br>`"last_name": "Smith" } ]}`<br>`$users[].`<br>`{first_name,last_name} ->`<br>`[<<"John","Doe">>,`<br>`<<"Steve","Smith">>]` |

| Selector | Description | Examples |
| --- | --- | --- |
| `$a[_]` | **Flatten Array Selector** — Selects the values of an array and flattens the dimension indicated by the underscore by one level. | `{`<br>`a: {`<br>`b: [`<br>`{c: [1,2,3] },`<br>`{c: [4,5,6] }`<br>`]`<br>`}`<br>`}`<br>`$a.b[_].c -> [1,2,3,4,5,6]` |
| `$a[!]` | **Compact Array Selector** — Selects the values of an array and removes any NULL values from the array at this level in the array. | `{`<br>`a: {`<br>`b: {`<br>`c: [1,null,2,null,3]`<br>`}`<br>`}`<br>`}`<br>`$a.b.c[!] -> [1,2,3]` |

For more examples of using JSON selectors in data pipelines, see **JSON Selectors Examples in Data Pipelines**.

## NULL and Empty Handling for JSON Scalars

The Ocient System handles all JSON NULL, empty, and missing values in the same way. The system loads these values as `NULL`. These values fail to load into non-nullable columns.

Provide an explicit default in the pipeline using `IF_NULL` or `COALESCE` or use the `COLUMN_DEFAULT_IF_NULL` option to accept the configured column default instead of attempting to load `NULL` values.

## NULL and Empty Handling for JSON Arrays

The Ocient System handles NULL, empty, and missing values the same way for arrays as for scalars. The system converts a value that is NULL, empty, or missing to NULL and loads it as `NULL`.

Provide an explicit default in the pipeline or use the `COLUMN_DEFAULT_IF_NULL` option to accept the configured column default instead of attempting to load `NULL`.

## NULL and Empty Handling for JSON Tuples

All the rules for handling NULL, empty, and missing elements that apply to scalars and arrays also apply to tuples. If any part of the selector is NULL, empty, or missing, data pipeline loading converts that value to `NULL`.

Additionally, because you can apply functions to tuple elements (and not array elements), you can use the `NULL_IF` function to convert a tuple element to `NULL`. For example, `tuple<<char,varchar>>($a.name, NULL_IF($a.hometown, 'N/A') )` indicates to the pipeline that the string `'N/A'` signifies `NULL` for the `hometown` element but not for the `name` element.

# Load Parquet Data

The data pipeline functionality enables loading Parquet files with this configuration.

### File Configuration

- Files should have row groups of less than 128 MB. Larger row groups can impact memory usage during loading, and row groups of 512 MB can cause loading failures on 1 TB or more data sets.
- Encoding fields in a Parquet file reduces the space of the file on disk but can impact memory usage during loading. Enable encoding on fields that you expect to have less than 256 unique values and for fields that contain short strings. You do not have to encode other fields.

### Multiple Files

- You can load row groups of multiple Parquet files in parallel. For large data sets, load the data set as multiple files.
- Loading files with differing schemas is not supported.

You can load Parquet files from these data pipeline source types:

- `S3` — AWS S3 or any S3-compatible object store.
- `FILESYSTEM` — A local or shared file system reachable from each Loader Node.
- `HDFS` — An Apache® Hadoop® Distributed File System (HDFS) cluster reachable from each Loader Node.

Use selectors as you do when loading JSON data to specify data to load.

© 2026 Ocient, Inc

You must select a leaf element, an array, or a tuple with your selector. This is stricter than using JSON selectors, which can directly select array fields and JSON object fields.

Example: `{"a": [1,2,3], "b": {"c": 1}}`

You can extract with any of the selectors in JSON: `$a, $a[], $b, $b.c`

However, Parquet only allows for the selectors: `$a[], $b.c`

This example assumes this schema:

```
// List<String> (list non-null, elements nullable)
required group my_list (LIST) {
  repeated group list {
    optional binary element (UTF8);
  }
}
```

The selector must be `$my_list[]`, which includes the array syntax.

For details, see **Parquet Selectors Examples in Data Pipelines**.

When you use the `FORMAT PARQUET` option with an AWS S3 source, the `ENDPOINT` option is required in the `CREATE PIPELINE` SQL statement.

Parquet is not supported for Kafka sources because Parquet is columnar, whereas Kafka is row-based. If you specify the `FORMAT PARQUET` option with a Kafka source, the `CREATE PIPELINE` SQL statement returns an error.

Auto-casting in Parquet does not support the automatic conversion to `VARCHAR` columns. You must explicitly cast data to the `CHAR` data type when you convert Parquet data that is not string data to a `VARCHAR` column or `VARCHAR` function argument.

The Ocient System treats Parquet selectors as lowercase. To use case-sensitive selectors, you must enclose the selector in double quotation marks. For example, `$"testSelector"`.

## Schema Evolution

The Ocient System supports schema evolution when you load a set of Parquet files. Specifically, if the pipeline selects a set of Parquet files where an individual file might

have more or fewer columns than another, the system attempts to merge those schemas together to support loading without requiring you to create the pipeline again.

For example, the `test_table` table has three columns.

SQL

```
CREATE TABLE test_table (
  col_a INT NULL,
  col_b VARCHAR NULL,
  col_c VARCHAR NULL
);
```

You have two Parquet files with these schemas:

Text

```
message file1_schema {
  OPTIONAL INT32 col_a;
  OPTIONAL BYTE_ARRAY col_b (UTF8);
}

message file2_schema {
  OPTIONAL BYTE_ARRAY col_b (UTF8);
  OPTIONAL BYTE_ARRAY col_c (UTF8);
}
```

However, you must specify how to handle the schema evolution within the `EXTRACT` SQL statement. You can choose to sample the first file only for its schema or sample the entire data set to merge the schemas together. This DDL statement samples on one file.

SQL

```
EXTRACT
  FORMAT parquet
  SCHEMA (INFER_FROM sample_file)
```

The disadvantage is that sampling multiple files can potentially take a long time (scaling with the number of files in the data set) when you execute the `CREATE PIPELINE` and

`START PIPELINE` SQL statements. If you know that all of the Parquet files have the same schema, use this syntax.

The Ocient System does not support the case where a column within the schema changes type. For example, if `col_a` is an `INT` type in one file and a `VARCHAR` type in another.

The default behavior of schema evolution infers the schema from one file. Use this syntax to infer from one file.

```
SQL

EXTRACT
  FORMAT parquet
  SCHEMA (INFER_FROM sample_file)
```

## Parquet Type Mapping

Parquet data types are separated into primitive and logical types. The Ocient System converts these types to Ocient SQL types. See these tables for the respective conversions.

| Parquet Primitive Type | Ocient SQL Type |
|---|---|
| `BOOLEAN` | `BOOLEAN` |
| `INT32` | `INT` |
| `INT64` | `BIGINT` |
| `INT96` | `TIMESTAMP` |
| `FLOAT` | `FLOAT` |
| `DOUBLE` | `DOUBLE` |
| `BYTE_ARRAY` | `VARCHAR` |
| `FIXED_LEN_BYTE_ARRAY` | `VARCHAR` |

| Parquet Logical Types | Ocient SQL Type |
|---|---|
| `STRING` | `VARCHAR` |
| `UTF8` | `VARCHAR` |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Parquet Logical Types | Ocient SQL Type |
|---|---|
| `ENUM` | `VARCHAR` |
| `UUID` | `UUID` |
| `INT8` | `TINYINT` |
| `INT16` | `SMALLINT` |
| `INT32` | `INT` |
| `INT64` | `BIGINT` |
| `UINT8` | `SMALLINT` |
| `UINT16` | `INT` |
| `UINT32` | `BIGINT` |
| `UINT64` | `BIGINT` |
| `DECIMAL` | `DECIMAL` |
| `DATE` | `DATE` |
| `TIME` | `TIME` |
| `TIME_MILLIS` | `TIME` |
| `TIME_MICROS` | `TIME` |
| `TIMESTAMP` | `TIMESTAMP` |
| `TIMESTAMP_MILLIS` | `TIMESTAMP` |
| `TIMESTAMP_MICROS` | `TIMESTAMP` |
| `DURATION` | `BIGINT` |
| `JSON` | `VARCHAR` |
| `BSON` | `VARCHAR` |

- The `INTERVAL` data type is not supported.
- The `UINT64` data type can overflow the `BIGINT` conversion.
- The `DURATION` data type conversion to `BIGINT` preserves the underlying units. For example, the number of microseconds stays as microseconds in the `BIGINT` data type.

Further, Parquet contains nested types that the Ocient System also converts to SQL types, as shown in this table.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Parquet Nested Types | Ocient SQL Type |
| --- | --- |
| `LIST` | `TYPE[]` |
| `TUPLE` | `TUPLE` |

## Parquet Loading Examples

### Load Parquet Files from AWS S3

Create a data pipeline that loads Parquet files using an AWS S3 bucket. Specify the bucket, endpoint, access key identifier, secret access key, and filter options to find all Parquet files in the specified file path. Use the `parquet_base_table` table to store the loaded data. Retrieve the integer, text, floating point, double, integer, JSON, and BSON fields.

SQL

```
CREATE PIPELINE testpipeline
    SOURCE S3
        BUCKET 'testbucket'
        ENDPOINT 'https://endpoint'
        ACCESS_KEY_ID ''
        SECRET_ACCESS_KEY ''
        FILTER_GLOB '/data/*/2024/*/*.parquet'
        PREFIX '/data/orders/2024/11/'
    EXTRACT
        FORMAT PARQUET
INTO parquet_base_table
SELECT $int32_field AS int32_field,
    $utf8_field as utf8_field,
    $float_field as float_field,
    $double_field as double_field,
    $int64_field as int64_field,
    $json_field as json_field,
    $bson_field as bson_field;
```

### Load Parquet Files from HDFS

This example loads Parquet files directly from HDFS. The pipeline reads files from the `hdfs-namenode:9000` endpoint that match the `/orders/*.parquet` filter, extracts them as

Parquet files, and inserts them into the `orders` table.

SQL

```
CREATE PIPELINE orders_pipeline
  SOURCE HDFS
    ENDPOINT 'hdfs-namenode:9000'
    FILTER '/orders/*.parquet'
  EXTRACT
    FORMAT parquet
    SCHEMA {INFER_FROM sample_file}
  INTO orders
  SELECT
    $id AS id,
    $user_id AS user_id,
    $product_id AS product_id,
    $subtotal AS subtotal,
    $created_at AS created_at;
```

## Parquet File-Partitioned Data

With Parquet, you can load file-partitioned data from Parquet files using the file path structure. Use the filter set in the file path using the Apache® Hive™ naming standards.

Assume files with these file paths.

Shell

```
s3://data/orders/2024/11/dt=2024-11-24/file.parquet
.../dt=2024-11-25/file.parquet
.../dt=2024-11-26/file.parquet
...
```

Load the data values in the Parquet file partitions using the `METADATA` function with the Hive partition syntax and the specified partition key `dt` from the file paths.

© 2026 Ocient, Inc

SQL

```
SELECT int32_field,
    utf8_field,
    float_field,
    double_field,
    int64_field,
    json_field,
    bson_field,
    METADATA('hive_partition','dt') AS file_date;
```

For details about this syntax, see **Load Metadata and File-Based Partitioned Data in Data Pipelines**.

# Load XML Data

You can load data in XML format into the Ocient System. The system supports XML tags, basic elements, nested elements, and CDATA, but it does not support XML arrays and attributes.

## Supported XML Selectors

Like JSON selectors, you can select XML data using the `$` symbol followed by a list of dot-separated JSON keys.

> The system treats XML selectors as lowercase. To use case-sensitive selectors, you must enclose the selector in double quotation marks, such as `$"testSelector"`. With case-sensitive selectors having multiple keys, each key needs double quotation marks, such as `$"testData"."Responses"."SuccessResponse"`.

The system does not support XML array and tuple selectors.

## XML Loading Example

Assume an XML file with this data.

XML

```xml
<root>
  <person>
    <name>Barbara Smith</name>
    <address>
      <city>New York</city>
      <zip>12345</zip>
    </address>
    <note><![CDATA[Personal IP <b>127.0.0.1</b>]]></note>
  </person>
</root>
```

Create a table to contain the IP address record:

- `name` — Name
- `city` — Name of the city
- `zip` — Zip code
- `personal_ip` — IP address

SQL

```sql
CREATE TABLE example_xml(
    name VARCHAR NOT NULL,
    city VARCHAR NOT NULL,
    zip VARCHAR NOT NULL,
    personal_ip IPV4 NOT NULL
);
```

Create a data pipeline `xml_pipeline` that loads the XML file `test.xml` using an AWS S3 bucket. Specify the bucket, endpoint, access key identifier, secret access key, and filter options to find the XML file in the specified path. Use the `example_xml` table to store the loaded data. Use JSON selectors to parse the file and data in each XML tag.

The system parses the `CDATA` section in the `note` tag as the literal string `Personal IP <b>127.0.0.1</b>`. Use the `SUBSTRING` function to extract the IP address and then transform it into an IPV4 type with the `IPV4` function. For details, see the **SUBSTRING** and **IPV4** functions.

SQL

```sql
CREATE PIPELINE xml_pipeline
    SOURCE S3
        BUCKET 'testbucket'
        ENDPOINT 'https://endpoint'
        ACCESS_KEY_ID ''
        SECRET_ACCESS_KEY ''
        FILTER_GLOB '/data/text.xml'
    EXTRACT
        FORMAT XML
INTO example_xml
SELECT
    $"root"."person"."name" as name,
    $"root"."address"."city" as city,
    $"root"."address"."zip" as zip,
    IPV4(SUBSTRING($"root"."person"."note", 16, 9)) as personal_ip;
```

# JSON Selectors Examples in Data Pipelines

Examples for selecting scalar values, arrays, nested fields, and NULL values from JSON records in Ocient data pipelines using field-selector expressions.

The data pipeline functionality enables you to load data in the structured JSON data format. Use these examples to see how you can access the structure in different ways. For an overview of loading JSON data, see:

- **Loading JSON Data**
- **Data Pipeline Load of JSON Data from Kafka**

## Scalar Extraction from JSON

These examples load a scalar into the `VARCHAR` column named `customer_name`. Use the `CREATE TABLE` SQL statement to create the table with this column.

SQL

```sql
CREATE TABLE my_schema.my_table (customer_name VARCHAR NOT NULL);
```

For a JSON file with the value at the top level, the selector can refer to the key directly.

Load a file with this data.

JSON

```json
{"name": "John"}
```

Use the selector `$name`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $name AS customer_name;
```

For a JSON file that has a nested value, you need a complex selector.

JSON

```
{"a": {"b": {"name": "John"}}}
```

In this case, the same `CREATE PIPELINE` statement for this file has `$a.b.name` instead of `$name`.

SQL

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $a.b.name AS customer_name;
```

## NULL and Empty Handling for JSON Scalars

The Ocient® System handles all JSON NULL, empty, and missing values in the same way. The system loads these values as `NULL`. These values fail to load into non-nullable columns. Provide an explicit default in the pipeline or use the `COLUMN_DEFAULT_IF_NULL` option to accept the configured column default instead of attempting to load `NULL` values.

The JSON data contains this information.

JSON

```
{"a": {"b": {"name": "John"}}}
{"blah": {}}
```

In this case, the output table has two rows because there are two records in the JSON source file.

SQL

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $a.b.name AS customer_name;
```

Output

SQL

```
Ocient> select * from my_schema.my_table;
name
--------------------------------------------
John
NULL
Fetched 2 rows
```

When you load all these JSON files with the same pipeline definition, the Ocient System creates a table with the same two rows.

The middle value is empty.

JSON

```
{"a": {"b": {"name": "John"}}}
{"a": {"b": {}}}
```

The middle value is NULL.

JSON

```
{"a": {"b": {"name": "John"}}}
{"a": {"b": null}
```

The leaf value is NULL.

JSON

```
{"a": {"b": {"name": "John"}}}
{"a": {"b": {"name": null}}}
```

## Array Extraction from JSON

Supported array extraction scenarios are:

- One-dimensional arrays.
- Multi-dimensional arrays.
- Array projection is the nested application of JSON selectors over the elements of arrays for both one-dimensional and multidimensional arrays.
- Arbitrary nesting of arrays within JSON objects, including splitting array dimensions across the JSON path.
- Loading individual array elements, which can also be arrays.
- Transforming array elements using the **TRANSFORM** function.

## One-Dimensional Arrays

The next few examples load the same data into the `my_table` table both directly and using array projection.

SQL

```
CREATE TABLE my_schema.my_table (customer_names VARCHAR[] NOT NULL);
```

Load data directly from a JSON array of strings. The JSON data contains this information.

JSON

```
{
  "a": {
    "b": {
      "names": ["John", "Bob", "Rajiv"]
    }
  }
}
```

SQL

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $a.b.names[] AS customer_names;
```

Output

SQL

```
Ocient> select * from my_schema.my_table;
customer_names
------------------------------------------------------------------------------
[John, Bob, Rajiv]
Fetched 1 row
```

## Array Projection

Array projection is the application of the specified selector over all elements in an array, similar to a for loop.

Load data using array projection into the same table using this JSON data.

JSON

```
{ "a": [ {"name": "John", "hometown": "Chicago"},
         {"name": "Bob", "hometown": "Cucamonga"},
         {"name": "Rajiv", "hometown": "Glendale Heights"} ] }
```

SQL

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $a[].name AS customer_names;
```

Output

SQL

```
Ocient> select * from my_schema.my_table;
customer_names
--------------
[John, Bob, Rajiv]
Fetched 1 row
```

The output of both loading operations is the same.

Repeat this example with data in an array that contains nested objects. The JSON file contains this information.

JSON

```
{ "a": [ {"b": {"name": "John", "hometown": "Chicago"}},
         {"b": {"name": "Bob", "hometown": "Cucamonga"}},
         {"b": {"name": "Rajiv", "hometown": "Glendale Heights"}} ] }
```

SQL

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $a[].b.name AS customer_names;
```

Output

SQL

```
Ocient> select * from my_schema.my_table;
customer_names
------------------------------------------------------------------------------
[John, Bob, Rajiv]
Fetched 1 row
```

The output is still the same.

## Multi-Dimensional Arrays

Multi-dimensional arrays work similarly to one-dimensional arrays.

These examples load the same data into the `my_table` table both directly, and then using array projection.

SQL

```
CREATE TABLE my_schema.my_table (customer_names VARCHAR[][][] NOT NULL);
```

Load data directly from a JSON array of strings. The JSON file contains this information.

JSON

```
{ "a": {
    "b": {
      "names": [
        [["John", "Bob", "Rajiv"], ["Anna", "Hanna", "Vanna", "Rosanna"]],
        [["Masha", "Natasha", "Sasha"], ["Chad", "Thad", "Brad"]]]    }
} }
```

SQL

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $a.b.names[][][] AS customer_names;
```

Load data using array projection. The JSON file contains this information.

JSON

```
{
    "a": [
        [
            [
                {"b": {"name": "John", "hometown": "Chicago"}},
                {"b": {"name": "Bob", "hometown": "Cucamonga"}},
                {"b": {"name": "Rajiv", "hometown": "Glendale Heights"}},
            ],
            [
                {"b": {"name": "Anna", "hometown": "Chicago"}},
                {"b": {"name": "Hanna", "hometown": "Cucamonga"}},
                {"b": {"name": "Vanna", "hometown": "Glendale Heights"}},
                {"b": {"name": "Rosanna", "hometown": "Mahwah"}},
            ],
        ],
        [
            [
                {"b": {"name": "Masha", "hometown": "Boston"}},
                {"b": {"name": "Natasha", "hometown": "Cambridge"}},
                {"b": {"name": "Sasha", "hometown": "Summerville"}},
            ],
            [
                {"b": {"name": "Chad", "hometown": "Champaign"}},
                {"b": {"name": "Thad", "hometown": "Urbana"}},
                {"b": {"name": "Brad", "hometown": "Mahomet"}},
            ],
        ],
    ]
}
```

`$a[][][].b.name` accesses each object, such as `{"b": {"name": "John", "hometown": "Chicago"}}`, and uses `b.name` to apply this nested attribute selector on all of the elements in the inner arrays.

© 2026 Ocient, Inc

SQL

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $a[][][].b.name AS customer_names;
```

Output

SQL

```
Ocient> select * from my_schema.my_table;
customer_names
--------------------------------------------------------------------------------
[[[John, Bob, Rajiv], [Anna, Hanna, Vanna, Rosanna]], [[Masha, Natasha, Sasha],
[Chad, Thad, Brad]]]
Fetched 1 row
```

The output of both loading operations is the same.

## Multi-Dimensional Arrays With Dimensions Split Across the JSON Path

To load a two-dimensional array, for example, use a one-dimensional array that contains JSON objects, each of which contains another one-dimensional array. Load the relevant parts of this JSON object into a two-dimensional array.

In this example, the column has `VARCHAR[][]` type and the `SELECT` expression is `$x.a[].b.c[].name`. The loaded data is a two-dimensional array of names.

The JSON file contains this information.

JSON

```
{
    "x": {
        "a": [
            {
                "b": {
                    "c": [
                        {"name": "John", "hometown": "Chicago"},
                        {"name": "Bob", "hometown": "Cucamonga"},
                        {"name": "Rajiv", "hometown": "Glendale Heights"},
                    ]
                }
            },
            {
                "b": {
                    "c": [
                        {"name": "Anna", "hometown": "Chicago"},
                        {"name": "Hanna", "hometown": "Cucamonga"},
                        {"name": "Vanna", "hometown": "Glendale Heights"},
                        {"name": "Rosanna", "hometown": "Mahwah"},
                    ]
                }
            },
        ]
    }
}
```

SQL

```
CREATE TABLE my_schema.my_table (customer_names VARCHAR[][]);
```

s

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $x.a[].b.c[].name AS customer_names;
```

Output

SQL

```
Ocient> select * from my_schema.my_table;
customer_names
--------------------------------------------------------------------------------
[[John, Bob, Rajiv], [Anna, Hanna, Vanna, Rosanna]]
Fetched 1 row
```

The output is a two-dimensional array of names.

## Extract Data from Individual Array Elements

Extract data from an element of a JSON array. That element can also be an array.

In this example, extract the first element of `a`, which is an array. JSON array indexes start at 1 so that all array indexing in Pipelines are consistent with the SQL standard.

The JSON file contains this information.

JSON

```
{
    "a": [
        {"b": [{"name": "John", "hometown": "Chicago"}]},
        {
            "b": [
                {"name": "Bob", "hometown": "Cucamonga"},
                {"name": "Rajiv", "hometown": "Glendale Heights"},
            ]
        },
        {"b": [{"name": "Rajiv", "hometown": "Glendale Heights"}]},
    ]
}
```

SQL

```
CREATE TABLE my_schema.my_table (customer_names VARCHAR[]);
```

SQL

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $a[2].b[].name AS customer_names;
```

## Output

SQL

```
Ocient> select * from my_table.my_schema;
customer_names
--------------------------------------------------------------------------------
[Bob, Rajiv]
Fetched 1 row
```

## NULL and Empty Handling for JSON Arrays

The Ocient System handles NULL, empty, and missing values the same way for arrays as for scalars. The system converts a value that is NULL, empty, or missing to NULL and loads it as `NULL`.

Provide an explicit default in the pipeline or use the `COLUMN_DEFAULT_IF_NULL` option to accept the configured column default instead of attempting to load `NULL`.

## Tuples of Scalars

Data pipeline loading supports tuples of scalars in the JSON source. The recommended way of specifying tuples is to use an individual JSON selector for each tuple element, such as `$a.b` or `$a.c`.

You can apply functions to tuple elements.

## Tuple Construction

This example loads two strings into a simple tuple.

JSON

```
{"users_hometowns": {"a": {"name": "Bob", "hometown": "Cucamonga"}}}
```

SQL

```
CREATE TABLE my_schema.my_table (users_hometowns TUPLE<<VARCHAR,VARCHAR>>);
```

SQL

```
CREATE PIPELINE my_pipeline
...
SELECT
    tuple<<char,char>>($users_hometowns.a.name, $users_hometowns.a.hometown)
    AS users_hometowns;
```

© 2026 Ocient, Inc

Output

```sql
Ocient> select * from my_schema.my_table;
users_hometowns
-------------------------------------------------------------------------------
<<Bob, Cucamonga>>
Fetched 1 row
```

## Advanced Tuple Construction

Use these examples to explore how to construct more complex tuples with nested objects and arrays.

### Select Fields from a Nested Object into a Tuple

When the target fields are nested inside a named object, prefix the braces with the path to that object.

Selector:

```
$a.{b, c}
```

Transform equivalent:

```
tuple($a.b, $a.c)
```

This data pipeline constructs a `TUPLE<<VARCHAR, INT>>` from fields `b` and `c` inside object `a`.

SQL

```
PREVIEW PIPELINE test_pl
    SOURCE INLINE '{"a": {"b": "two", "c": 2}}'
    EXTRACT FORMAT JSON
    INTO test.tgt_tbl
    SELECT $a.{b, c} AS tgt_col4;
```

Output

Text

```
tgt_col4
--------------------------------------------------------------------------------
("two", 2)
```

### Select an Array of Tuples from an Array of Objects

Appending `[]` to the parent path maps the tuple selector over every element in the array, producing an array of tuples.

Selector:

Text

```
$a[].{b, c}
```

Transform equivalent:

Text

```
zip_with($a[].b, $a[].c, tuple)
```

This data pipeline produces a `TUPLE<<INT, VARCHAR>>[]` from an array of objects, each containing fields `b` and `c`.

SQL

```
PREVIEW PIPELINE test_pl
    SOURCE INLINE '{"a": [{"b": 1, "c": "John"},
        {"b": 2, "c": "Bob"},
        {"b": 3, "c": "Rajiv"}]}'
    EXTRACT FORMAT JSON
    INTO test.tgt_tbl
    SELECT $a[].{b, c} AS tgt_col5;
```

Output

Text

```
tgt_col5
--------------------------------------------------------------------------------
[(1, "John"),(2, "Bob"),(3, "Rajiv")]
```

### Select a Tuple Containing an Array Element

Individual fields inside braces can have their own brackets `[]` to indicate that the field is an array. This selector produces a tuple with one element, an array, and the other a scalar.

Selector:

Text

```
$a.{b[], c}
```

Transform equivalent:

Text

```
tuple($a.b[], $a.c)
```

This data pipeline constructs a `TUPLE<<VARCHAR[], INT>>` where the first element is an array of strings and the second element is an integer.

SQL

```
PREVIEW PIPELINE test_pl
    SOURCE INLINE '{"a": {"b": ["John", "Bob", "Rajiv"], "c": 3}}'
    EXTRACT FORMAT JSON
    INTO test.tgt_tbl
    SELECT $a.{b[], c} AS tgt_col6;
```

Output

Text

```
tgt_col6
--------------------------------------------------------------------------------
([John,Bob,Rajiv], 3)
```

### Select an Array of Tuples with an Array Element

Combining brackets `[]` on the parent path with `[]` on a child field produces an array of tuples where each tuple contains an array element and a scalar element.

Selector:

Text

```
$a[].{b[], c}
```

Transform equivalent:

Text

```
zip_with($a[].b[], $a[].c, tuple)
```

This data pipeline produces a `TUPLE<<VARCHAR[], INT>>[]` from an array of objects that each contain a nested array.

SQL

```
PREVIEW PIPELINE test_pl
    SOURCE INLINE '{"a": [{"b": ["John", "Bob", "Rajiv"], "c": 4},
        {"b": ["Rajiv", "Bob", "John"], "c": 5}]}'
    EXTRACT FORMAT JSON
    INTO test.tgt_tbl
    SELECT $a[].{b[], c} AS tgt_col7;
```

Output

Text

```
tgt_col7
--------------------------------------------------------------------------------
[([John,Bob,Rajiv], 4),([Rajiv,Bob,John], 5)]
```

### Select a Tuple with Nested Tuple Elements

Nesting tuple selectors produces tuples where the elements are also tuples.

Selector:

Text

```
$.{a.{b, c}, d.{e, f}}
```

Transform equivalent:

Text

```
tuple(tuple($a.b, $a.c), tuple($d.e, $d.f))
```

This data pipeline constructs a `TUPLE<<TUPLE<<VARCHAR, INT>>, TUPLE<<INT, VARCHAR>>>>` from two nested objects.

SQL

```
PREVIEW PIPELINE test_pl
    SOURCE INLINE '{"a": {"b": "John", "c": 6},
        "d": {"f": "Bob", "e": 7}}'
    EXTRACT FORMAT JSON
    INTO test.tgt_tbl
    SELECT $.{a.{b, c}, d.{e, f}} AS tgt_col8;
```

Output

Text

```
tgt_col8
--------------------------------------------------------------------------------
(("John", 6), ("Bob", 7))
```

### Select an Array of Tuples with a Nested Tuple Element

A dot-brace group preceded by `.` (with no field name) creates an inline tuple element within an outer tuple. When you combine such an element with brackets `[]` on the parent path, this selector produces an array of tuples where one element is a tuple.

Selector:

Text

```
$a[].{b, .{c[1], c[2], c[3]}}
```

Transform equivalent:

Text

```
zip_with($a[].b, zip_with($a[].c[1], $a[].c[2], $a[].c[3], tuple), tuple)
```

This data pipeline produces a `TUPLE<<INT, TUPLE<<VARCHAR, VARCHAR, VARCHAR>>>>[]` by selecting a scalar field and an inline tuple of indexed array elements.

SQL

```
PREVIEW PIPELINE test_pl
    SOURCE INLINE '{"a": [{"c": ["John", "Bob", "Rajiv"], "b": 4},
        {"c": ["Rajiv", "Bob", "John"], "b": 5}]}'
    EXTRACT FORMAT JSON
    INTO test.tgt_tbl
    SELECT $a[].{b, .{c[1], c[2], c[3]}} AS tgt_col10;
```

Output

Text

```
tgt_col10
--------------------------------------------------------------------------------
[(4, ("John", "Bob", "Rajiv")),(5, ("Rajiv", "Bob", "John"))]
```

## Applying Functions (Transformations) To Tuple Elements

In this example, load a tuple where elements have different types, `VARCHAR` and `TIMESTAMP`, and where the second element has to be converted from a JSON string into an Ocient timestamp. The JSON file contains this information.

JSON

```
{"event_timestamp": {"event": "my_event", "timestamp": "1980-02-03 15:16:17.12345
```

SQL

```
CREATE TABLE my_schema.my_table (event_timestamp TUPLE<<VARCHAR,TIMESTAMP>> NOT N
```

```sql
CREATE PIPELINE my_pipeline
...
SELECT
    tuple<<char,timestamp>>($event_timestamp.event,
    TO_TIMESTAMP(char($event_timestamp.timestamp), 'yyyy-MM-dd HH:mm:ss.SSSSSS'))
    AS event_timestamp;
```

Output

```sql
Ocient> select * from  my_schema.my_table;
event_timestamp
--------------------------------------------------------------------------------
<<my_event, 1980-02-03 15:16:17.123450000>>
Fetched 1 row
```

The output table has one row of tuples.

## NULL and Empty Handling for JSON Tuples

All the rules for handling NULL, empty, and missing elements that apply to scalars and arrays also apply to tuples. If any part of the selector is NULL, empty, or missing, data pipeline loading converts that value to `NULL`.

Additionally, because you can apply functions to tuple and array elements, you can use the `NULL_IF` function to convert a tuple element to `NULL`. For example, `tuple<<char,varchar>>( $a.name, NULL_IF($a.hometown, 'N/A') )` indicates to the pipeline that the string `'N/A'` signifies `NULL` for the `hometown` element but not for the `name` element.

## Special Characters in JSON Keys

This example shows loading data where the JSON key names contain a special character.

Create a table for the load using the `customer_name` column.

SQL

```
CREATE TABLE my_schema.my_table (customer_name VARCHAR NOT NULL);
```

Load a file with this data. The JSON key name contains the `-` special character.

JSON

```
{"first-name": "John"}
```

Use double quotes for the selector `$first-name` in the `CREATE PIPELINE` SQL statement.

SQL

```
CREATE PIPELINE my_pipeline
    SOURCE filesystem
        FILTER 'data.json'
    EXTRACT
        FORMAT json
    INTO my_schema.my_table
    SELECT
        $"first-name" AS customer_name;
```

# Array Extraction Operations

Other operations exist in the source field selector syntax to flatten or compact arrays while extracting the data.

## Flatten Arrays

Flattening means that the extracted array should not increase the rank, and instead, sub-arrays should be concatenated. To flatten an array, use the underscore character in the array selector (e.g., `$data.array[_]`).

### Example

This JSON data contains a nested array with two sub-arrays having data `[1,2,3]` and `[4,5,6]`.

JSON

```
{
  a: {
    b: [
      {c: [1,2,3] },
      {c: [4,5,6] }
    ]
  }
}
```

Flatten the nested array.

SQL

```
a.b[_].c[]
```

Output: `[1,2,3,4,5,6]`

This selected array has rank 1, and not 2. Contrast this with the non-flattened selector `a.b[].c[]`, which would have the output `[[1,2,3],[4,5,6]]`.

You can also flatten arrays with the `FLATTEN` function. For details, see **Array Data Transformation Functions**. The functionality of the operator and function is equivalent.

## Compact Arrays

Compaction eliminates NULL values from the output data. The exact bit pattern of NULL in the source data is source-type dependent. For JSON, `null` is a literal keyword that is unambiguous. For CSV or other less-defined types, the configuration determines which exact bits equate to NULL. To compact an array, use the exclamation mark character in the array selector(e.g., `$data.array[!]`).

### Example

This JSON data contains a nested array with four NULL values.

JSON

```
{
  a: {
    b: {
      c: [ 1,null,2,null,3,null,null]
    }
  }
}
```

Compact the nested array.

SQL

```
a.b.c[!]
```

Output: `[1,2,3]`

You can also compact arrays with the `ARRAY_COMPACT` function. For details, see **Array Data Transformation Functions**. The functionality of the operator and function is equivalent.

# Parquet Selectors Examples in Data Pipelines

Examples for selecting columns from Parquet files in Ocient data pipelines using the Parquet schema, with SQL-style field references and links to references.

The data pipeline functionality enables you to load data in the Apache® Parquet™ data format. Use these examples to see how you can access the structure in different ways. For an overview of loading Parquet data, see **Data Pipeline Load of Parquet Data from S3**.

## Work with Parquet Selectors

The SELECT statement for a Parquet file uses the same syntax as the existing JSON selectors. This selection applies to lists, structures, and maps.

The Ocient® System retrieves its list of requested columns from the `SELECT` SQL statement. The columns correspond to the field names of the schema for the Parquet files for the load. The load retrieves required columns from the Parquet source files and leaves the other columns alone.

This example snippet shows a list of `["id", "name", "array[]", "a[].project", "my_map.key_name"]` as the fields to select from the data. The statement only retrieves the columns for `["id", "name", "array", "a", "my_map"]` in the row groups.

SQL

```
SELECT
    $id                     as id,
    $name                   as name,
    $array[]                as array,
    $a[].project            as projection,
    $my_map.key_name        as key_col
...
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

You must select a leaf element, an array, or a tuple with your selector. This is stricter than using JSON selectors, which can directly select array fields and JSON object fields.

Example: `{"a": [1,2,3], "b": {"c": 1}}`

You can extract with any of the selectors in JSON: `$a, $a[], $b, $b.c`

However, Parquet only allows for the selectors: `$a[], $b.c`

This example assumes this schema:

```
// List<String> (list non-null, elements nullable)
required group my_list (LIST) {
  repeated group list {
    optional binary element (UTF8);
  }
}
```

The selector must be `$my_list[]`, which includes the array syntax.

# Work with Complex Parquet Selectors

These examples show how to load a Parquet list and convert it to an array and how to load a map and convert it to a tuple.

## Load List as an Array Example

Create the `tips` table to store the tip inquiries a city receives. The columns are:

- `id` — Identifier as an integer
- `categories` — Categories as a list of strings
- `mayor` — Mayor as a string
- `mentions` — Mentions as a list of strings
- `service_name` — Service name as a non-nullable string
- `tags` — Tags as a list of strings
- `url` — URL as a string
- `username` — Username as a string

- `text` — Text description as a non-nullable string
- `venue_name` — Venue name as a non-nullable string

SQL

```
CREATE TABLE tips(
    id INT NOT NULL,
    categories VARCHAR(255)[],
    mayor VARCHAR(255),
    mentions VARCHAR(255)[],
    service_name VARCHAR(255) NOT NULL,
    tags VARCHAR(255)[],
    url VARCHAR(255),
    username VARCHAR(255),
    text VARCHAR(255) NOT NULL,
    venue_name VARCHAR(255) NOT NULL);
```

Create the `tips_pipeline` data pipeline for loading the tip data. Specify the Amazon® Web Services℠ (AWS℠) S3 source with bucket `ocient-docs`, object key `metabase_samples/parquet/tips.parquet`, and endpoint `https://s3.us-east-1.amazonaws.com`. The source format is Parquet.

© 2026 Ocient, Inc

SQL

```
CREATE PIPELINE tips_pipeline
    SOURCE S3
        BUCKET 'ocient-docs'
        OBJECT_KEY 'metabase_samples/parquet/tips.parquet'
        ENDPOINT 'https://s3.us-east-1.amazonaws.com'
    EXTRACT
        FORMAT parquet
INTO tips
SELECT
    $id AS id,
    $source.categories[] AS categories,
    $source.mayor AS mayor,
    $source.mentions[] AS mentions,
    $source."service" AS service_name,
    $source.tags[] AS tags,
    $source.url AS url,
    $source.username AS username,
    $text AS text,
    $venue.name AS venue_name;
```

Start the data pipeline. The data pipeline loads the `categories`, `mentions`, and `tags` columns as arrays.

SQL

```
START PIPELINE tips_pipeline;
```

## Load Map as a Tuple Example

This example uses the file `/tmp/to-load/locations.parquet` that contains a `MAP<STRING, DOUBLE>` field named `coordinates`. Each value of the map field contains `x` and `y` entries for the coordinates.

Create the `locations` table to store the map values. The `cartesian_coords` column is a tuple with two elements for the `x` and `y` coordinates.

SQL

```
CREATE TABLE locations(
    cartesian_coords TUPLE<<DOUBLE, DOUBLE>> NOT NULL);
```

Create the `locations_pipeline` data pipeline for loading the maps data. Specify the filter for the Parquet file `/tmp/to-load/locations.parquet`. The source format is Parquet. Select the `x` and `y` coordinates from the map.

SQL

```
CREATE PIPELINE locations_pipeline
    SOURCE filesystem
        FILTER '/tmp/to-load/locations.parquet'
    EXTRACT
        FORMAT parquet
INTO locations
SELECT
    TUPLE($coordinates.x, $coordinates.y) AS cartesian_coords;
```

Start the data pipeline. The data pipeline loads the `cartesian_coords` column as a tuple.

SQL

```
START PIPELINE locations_pipeline;
```

# Data Pipeline Behavior Considerations

Understand how Ocient data pipelines handle file resumption, Kafka offsets, exactly-once semantics, deduplication, and database and table dependencies.

Data pipelines enable you to load data from your chosen source into the OcientAIQ™ Unified Data Platform. For details about the syntax, see **Data Pipelines**. When you use data pipelines to load data, consider how to resume a pipeline with file loading, restart the pipeline with Apache® Kafka® loading, and review pipeline dependencies.

## Resume a Pipeline with File Loading

In many cases, a file-based pipeline stops executing before completion. You cannot resume a pipeline in a `COMPLETED` status.

To resume a pipeline, use the `START PIPELINE` SQL statement. Before you resume a pipeline, the status of the pipeline must be `FAILED`, `STOPPED`, or `QUIESCED`. A pipeline in the `QUIESCED` status resumes from a clean breakpoint with no missing or duplicate data. For details, see **QUIESCE PIPELINE**. When a pipeline resumes, individual files remain in their most recent status as defined in the `sys.pipeline_files` system catalog table. For `BATCH` pipelines, the Ocient® System does not add new files to the eligible file list when the pipeline resumes.

> ⚠ If you modify the contents of files during the loading process, the Ocient System might experience issues with deduplication that cause duplicated rows or missing data. Avoid modifying files after you start a pipeline for the first time.
>
> Creating new files on your data source does not impact deduplication logic.

The `START` operation groups files using their `extractor_task_id` and `stream_source_id` identifiers. The `stream_source_id` uniquely identifies partitions (i.e., an ordered list of files), and `extractor_task_id` identifies the batch that loads a group of partitions.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

When there are too many existing pipelines in the system, when you start a pipeline, the pipeline has the `QUEUED` status.

## File Statuses

The Ocient System considers files with the statuses `LOADED`, `LOADED_WITH_ERRORS`, or `SKIPPED` to be in the terminal status, whereas other file statuses are still in process. Special cases include:

- Completed Batches — If all the files in a particular batch have terminal status, then the pipeline does not attempt to reload the batch. These files have been completely processed, so the Ocient System ignores modifications to these files.
- In-Process Batches — If at least one file in a particular batch does not have terminal status, then the pipeline reloads the entire batch. The pipeline reprocesses the in-process batches and relies on row deduplication to prevent duplication of rows in the target tables.
  - Modifications to files in an in-process batch can be, but are not guaranteed, to be picked up by a restart.
  - Modifications to any files in this batch with the `LOADED`, `LOADED_WITH_ERRORS`, or `SKIPPED` statuses might cause issues with deduplication, leading to duplicate or missed data.
- Pending Files — The Ocient System does not assign all `PENDING` files to a partition. The pipeline attempts to load these files after reloading any in-progress batches.

## Load Duplicate Data from Files

Sometimes you might want to load the same data multiple times. If you want to load a second copy of the source data, you can either:

- Drop and recreate the pipeline to reset the `sys.pipeline_files` system catalog table.
- Create a second pipeline with a new name and the same configuration.

> When you truncate the target tables and restart the pipeline, the Ocient System does not reload the data.

## Restart with Kafka Loading

Ocient relies on the offset management and consumer group behavior in Kafka to deliver exactly-once loading semantics and to control the Ocient pipeline behavior.

### Kafka Offsets and Consumer Group Identifiers

If you set the `WRITE_OFFSETS` option to `true` (default value is `true`), the Kafka consumers commit offsets back to Kafka after data is considered durable in the database. The Kafka Broker stores these offsets as the last committed offset for the group identifier `group.id`.

For each pipeline, the group identifier defaults to `<systemId>__<databaseName>__<pipelineName>`, where the `<systemId>` is the identifier of your system, `<database-name>` is the name of your database, and `<pipeline-name>` is the name of the data pipeline. In most use cases, you should not manually change the `group.id` field for a pipeline.

Any Kafka streaming pipeline that has the same `group.id` starts consuming from its last committed offset, or if you do not set the value, the pipeline uses the Kafka `auto.offset.reset` policy to determine where to start. For details, see **Kafka offset management**.

> If you want to start loading from the beginning of a topic, configure an unused `group.id` field (or use a `group.id` field that did not commit any of its offsets back) and ensure the `auto.offset.reset` Kafka configuration is appropriately set in the `CONFIG` option.

### Kafka Streaming Pipeline Deduplication

The committed offset of a Kafka partition lags slightly behind the rows that have been loaded into Ocient. These lags do not cause an issue with data duplication. If you stop a pipeline before it can commit its most recent durable offset to Kafka, restarting the same pipeline starts loading from the last committed offset. However, the database deduplicates records sent twice for the same pipeline.

Ocient deduplicates Kafka data for the specified combination of pipeline identifier, Kafka topic, and the Kafka partition number.

© 2026 Ocient, Inc

While the consumer group offsets manage where the pipeline resumes loading, the Ocient System enforces the exactly-once loading of a Kafka partition only if you stop or restart a pipeline with the same pipeline identifier.

> ⚠ If you drop a pipeline and create a new one with the same name, the Ocient System creates a new pipeline identifier. The new pipeline does not deduplicate data against data that the original pipeline loaded. The `CREATE OR REPLACE PIPELINE` SQL statement also creates a new pipeline identifier and has the same effect on deduplication. To update a pipeline and preserve deduplication, use the `ALTER PIPELINE` SQL statement, which modifies the pipeline in place and retains its identifier. For details, see **Update a Pipeline**.

> ⚠ Do not run multiple pipelines concurrently with the same consumer group identifier. This action leads to unpredictable data duplication. If you want to increase the number of consumers that read from a Kafka topic, increase the value of the `CORES` parameter.

### Load Duplicate Data on Kafka

Sometimes you might want to load the same data multiple times. If you want to load a second copy of the source data from Kafka, you can either:

- Drop the pipeline, recreate it with the same name, and reset the consumer group offsets manually.
- Create a new pipeline with a different name and load from the beginning of the topic.

## Pipeline Database Dependency

Each pipeline belongs to a database. You cannot drop a database that has a running pipeline. To drop a database, ensure that all pipelines in the database are in a non-running status.

## Pipeline Table Dependency

Each pipeline has a target table. You cannot drop a table that has a running pipeline. To drop a table, ensure that all pipelines that are loading data into the table are in a non-running status.

# Transform Data in Data Pipelines

Transform data during loading in Ocient data pipelines using source field references and SQL transformation functions to clean and prepare records.

Data pipeline functionality supports data transformation during loading to efficiently convert and clean source data for your chosen table schema. You can use two broad classes of data transformation: source field references or SQL transformation functions.

## Source Field References

When you load data using a data pipeline, you reference extracted data using a special syntax named a source field reference. These expressions are either a named reference such as `$my_field` or a numeric field reference such as `$1`.

In structured data formats like JSON, more complex source field references allow you to transform the structured data into the required form. For example, you can extract an array of values from an array of nested objects with an expression such as `$data.items[].price`.

To learn more about transforming data with source field references, see:

- **Supported JSON Selectors**
- **Understand Source Fields and Data Formats**

## Supported Transformation Functions in Data Pipelines

Data pipeline loading supports numerous SQL functions for use in transforming data during loading. You can use these transformation functions in the `INTO ... SELECT` portion of a pipeline. Transformation functions generally match the syntax and behavior of the function you use when you query in Ocient®. The behavior might differ from querying behavior in two ways:

- Some additional functions exist that provide behavior that does not exist in queries.
- Some existing functions have extended behavior during loading that provides important capabilities that are not in queries.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

The types of transformation functions supported in loading include:

- Scalar data conversion and casting of data types
- Special loading transformation functions
- Date and time transformations
- Character data transformations
- Binary data transformations
- Array data transformations
- Logical operations transformations
- Network type functions
- Other data transformations
- Custom user-defined **Pipeline Functions** using Apache® Groovy™

## Scalar Transformation Functions and Casting

Scalar transformation functions include constructors, scalar data conversions, and data-casting functions.

| Name | Description | Supported Input Type | Return Type | Example SI Expression |
|---|---|---|---|---|
| `T[]\(X)` | Casts a string representation of an array of values or the result of a JSON array extraction expression to the corresponding array with data type `T` where `T` is a SQL data type. Multi-dimensional arrays are supported. To indicate an N-dimensional array cast, use N sets of square brackets in the casting function. All transformation functions can only apply to an array as a whole. To apply functions on an | CHAR | ARRAY[] | CSV: `DECIMAL(8,4` `($21) as` `decimal_2d_` `ol` JSON: `CHAR[]\` `($a.b.names` `names` `DECIMAL(8,2` `($a[].b.c[]` `) as prices` `CHAR[][][]\` `($names[][]` `names` |

| Name | Description | Supported Input Type | Return Type | Example SI Expression |
|---|---|---|---|---|
| | element-wise basis, see `TRANSFORM` in **Special Data Pipeline Transformation Functions**. | | | |
| `BIGINT(X)` | Converts the specified type to a 64-bit signed integer. | BIGINT<br>CHAR | BIGINT | CSV:<br>`BIGINT($22)`<br>`int64_col`<br>JSON:<br>`BIGINT($a.b`<br>`int64_col` |
| `BINARY(X)` | Translates a string representation of bytes and converts them to real bytes. The string representation expects hexadecimal representations that convert to the matching bytes with this function. Hexadecimal data is not case-sensitive. Example source data: `a891`, `F1D890` | CHAR | BINARY or VARBINARY | CSV:<br>`BINARY($30)`<br>`varbinary_c`<br>JSON:<br>`BINARY($a.b`<br>`varbinary_c` |
| `BOOLEAN(X)` | Handles textual representation of Booleans and converts them to its Boolean equivalent. You can represent `true` as any of these values: `"t", "true", "yes", "1", "y", "on"` `false` representation as any of these values: `"f", "false", "no", "0", "n", "off"` | CHAR | BOOL | CSV:<br>`BOOLEAN($23`<br>`bool_col`<br>JSON:<br>`BOOLEAN($a.`<br>`bool_col` |
| `BYTE(X)` | Supports characters and number or byte array representations. Interprets character data as the ASCII numeric representation of a byte. | CHAR | BYTE | CSV:<br>`BYTE($24) a`<br>`byte_col`<br>JSON:<br>`BYTE($a.b.c`<br>`byte_col` |

| Name | Description | Supported Input Type | Return Type | Example SI Expression |
| --- | --- | --- | --- | --- |
| | If you specify a byte array, the Ocient System uses the first element of the array. When the system converts text data to a byte, the function throws an error if the value is `> 127` or `< -128`.<br>Example:<br>`'101'` -> `101`<br>`'-23'` -> `-23` | | | |
| `CHAR(X)` | Converts the specified input type to its string representation. | CHAR<br>BINARY<br>FLOAT<br>DOUBLE<br>INT<br>BYTE<br>SMALLINT<br>DATE<br>BOOLEAN<br>UUID<br>ARRAY | CHAR or VARCHAR | CSV:<br>`CHAR($25) a`<br>`varchar_col`<br>`CHAR($26) a`<br>`char_col`<br>JSON:<br>`CHAR($a.b.c`<br>`varchar_col`<br>`CHAR($a.b.c`<br>`char_col`<br>`CHAR($array`<br>`]) as char_` |
| `DECIMAL(X,P,S)` | `X` is input data to convert to a decimal. `P` is the precision of the decimal (number of significant digits) and `S` is the scale (number of digits after the decimal point).<br>You can omit `P` and `S` or only `S`. In that case, the Ocient System defaults `P` to 31 and `S` to 16.<br>Example: | CHAR | DECIMAL | CSV:<br>`DECIMAL($27`<br>`as decimal_`<br>JSON:<br>`DECIMAL($a.`<br>`4) as decim` |

| Name | Description | Supported Input Type | Return Type | Example SI Expression |
|---|---|---|---|---|
| | `DECIMAL(30.0,4,2) -> 30.00` | | | |
| `DOUBLE(X)` | Converts the specified type to its double representation. | BINARY<br><br>CHAR | DOUBLE | CSV: `DOUBLE($28) double_col` JSON: `DOUBLE($a.b double_col` |
| `FLOAT(X)` | Converts the specified type to its float representation. | BINARY<br><br>CHAR | FLOAT | CSV: `FLOAT($29) float_col` JSON: `FLOAT($a.b. float_col` |
| `HASH(X,N)` | Translates a string representation of bytes and converts them to bytes. The string representation expects hexadecimal representations that convert to the matching bytes with this function. Hexadecimal data is not case-sensitive. `X` is the source data, such as: `a891` , `F1D890` `N` is the fixed number of bytes in the binary array. | CHAR | HASH | CSV: `HASH($23, 9 fixed_hash_ col` JSON: `HASH($a.b.c fixed_hash_ col` |
| `INT(X)` | Converts the specified type to a 32-bit signed integer. | DECIMAL<br>CHAR<br>SMALLINT | INT | CSV: `INT($31) as int32_col` JSON: `INT($a.b.c) int32_col` |
| `IP(X)` | Converts the specified string to an IPv6 address equivalent. `X` is the source data, such as: `2001:0db8:1234:5678:abcd:ef01:2345:6789` | CHAR | IP | CSV: `IP($32) as` JSON: `IP($a.b.c) ip_col` |

| Name | Description | Supported Input Type | Return Type | Example SI Expression |
|---|---|---|---|---|
| | `2001:db8:0:0:0:0:0:2` `192.0.2.1` | | | |
| `IPV4(X)` | Converts the specified string to an IPv4 address equivalent. `X` is the source data, such as: `192.0.2.1` | CHAR | IPV4 | CSV: `IPV4($32) a` `ipv4_col` JSON: `IPV4($a.b.c` `ipv4_col` |
| `SMALLINT(X)` | Converts the specified value to its 16-bit signed integer representation. | DECIMAL<br>CHAR<br>BYTE | SMALLINT | CSV: `SMALLINT($3` `int16_col` JSON: `SMALLINT($a` `as int16_co` |
| `ST_POINT(Long, Lat)` | Accepts a longitude and latitude coordinate for a geospatial point. Arguments must be of type `double` or string values that can convert to `double`. For WKT representation, see **ST_POINTFROMTEXT**. | Both DOUBLE<br><br>Both CHAR | `ST_POINT` | CSV: `ST_POINT($1` `as st_point` JSON: `ST_POINT($a` `$d.e.f) as` `st_point_co` |
| `ST_POINTFROMTEXT(X)` | Accepts the WKT text representation for `ST_POINT` with `X` and `Y` coordinates only. Example WKT representation: `'POINT(-40.5318` `11.8532)'` | CHAR | `ST_POINT` | `st_pointfro` `1)` `st_pointfro` `a.b.c)` |
| `TINYINT(X)` | Converts the specified value to an 8-bit signed integer. | CHAR | TINYINT | CSV: `TINYINT($34` `int8_col` JSON: `TINYINT($a.` `int8_col` |
| `TUPLE <<T,[T]*>> (X,[Y]*)` | Creates a tuple from the specified types. TUPLE supports arrays of tuples, but does not support tuples within tuples. | CHAR | TUPLE of type | CSV: `TUPLE<<INT,` `(7,2),TIMES` `NARY(7)>>($` `int_decimal` `amp_binary_` |

| Name | Description | Supported Input Type | Return Type | Example SI Expression |
|---|---|---|---|---|
| | The arguments to the TUPLE casting function can be either a single source value or must match the number of types defined in the TUPLE. If you specify a single value, the Ocient System infers individual elements of the tuple using the TUPLE format `(value1,value2,value3)`. Example source data: `(123,12.75)` is valid text data for a `TUPLE<<INT,DECIMAL(7,2)>>`. | | | `ol TUPLE<<INT, (7,2),TIMES NARY(7)>> ($4,$8,$1) int_decimal amp_binary_ ol_multi_ir` JSON: `TUPLE<<INT, (7,2),TIMES NARY(7)>>($ $c)) as int_decimal amp_binary_ ol` |
| `UUID(X)` | Creates a unique identifier from the specified value. Example source data: `'237e9877-e79b-12d4-a765-321741963000'` | CHAR | UUID | CSV: `UUID($34) a uuid_col` JSON: `UUID($a.b.c uuid_col` |

## Special Data Pipeline Transformation Functions

Special data pipeline transformation functions include functions that only exist in loading, such as the `METADATA` function to load special data during pipeline execution.

> `ARRAY_TRANSFORM`, `ARRAY_TRANSFORM_WITH_ORD`, and `ZIP_WITH_ORD` also transform arrays using a lambda function or reference function, but they are standard SQL functions rather than data pipeline transformation functions. For details, see **ARRAY_TRANSFORM**, **ARRAY_TRANSFORM_WITH_ORD**, and **ZIP_WITH_ORD** in **Array Functions and Operators**.

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| `EXPLODE_OUTER(array)` | Expands the contents of the specified one-dimensional array. | ARRAY | Elements of the array in their own row. | `EXPLODE_OUTER($ ta.response.res ses[].own") AS own` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| | By default, the array can contain a maximum of 8,191 elements. For supported options, see **Special Data Pipeline Transformation Functions**. | | | |
| `FILTER(T[], (T) -> Boolean)` | Filters elements in an array based on the logic in a lambda expression. The first argument is an expression that evaluates to an array that contains the elements to filter. The second argument is a lambda expression (or reference function) that returns `true` if an element should be retained.<br>The second argument must be of the form `(x T) -> BOOL`. This returns a boolean value for a specified element `x`. The type `T` of the element `x` is specified in the lambda function.<br>Elements in the first argument array are included in the resulting array when the lambda function returns `true` and excluded otherwise.<br>For supported | ARRAY<br><br>Lambda Function `(x T) -> BOOL` or Reference Function | The elements of the array that matched the filter criteria function. | `FILTER($data.na , (name CHAR) - length(name) >` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| | options and examples, see **Special Data Pipeline Transformation Functions**. | | | |
| `LOOKUP(lookup_source_name, value, join_column_name, return_column_name)` | Look up and load data in an external data source. For details, see **Load Data from External Sources in Data Pipelines**. | Varies based on the `value` argument. | Varies based on the returned data in the `return_column_name` argument. | `LOOKUP('sqlite_ , $2, 'firstnam 'id')` |
| `METADATA(key)` | Extracts the metadata value for the specified key from available metadata for the pipeline.<br>For supported key values, see **Load Metadata and File-Based Partitioned Data in Data Pipelines**. | CHAR | Varies based on the metadata key. | `METADATA('filen ') → '/path/to/file/ ers_1830374.jso` |
| `PARSE_DELIMITED_ARRAY(text, rank, array_element_delimiter, bracket_spec)` | Converts a string of text data representing an array into a `CHAR[]`.<br>For example, with data in the form `[1;2;3]`, executing `PARSE_DELIMITED_ARRAY('[1;2;3]', 1, ';', '[]')` returns a `CHAR[]` with the value `['1','2','3']`. | `text` is CHAR data that represents the text to convert to an array.<br><br>`rank` is an optional argument that represents the numeric rank of the output array. The default value is 1. You can only specify rank as a literal value because you cannot retrieve it dynamically from a source field selector.<br>`array_element_del` | CHAR[] | `PARSE_DELIMITED RAY($text_array PARSE_DELIMITED RAY($text_array 1, ';', '[]') PARSE_DELIMITED RAY($two_dim_te array, 2, ',', '[]')` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| | | `imiter` is an optional argument that contains the control character for delimiting array elements. For example, `','` indicates that a comma separates each element in the `text` character data. The default value definition comes from the `ARRAY_ELEMENT_DEL IMITER` value of the data pipeline.<br><br>`bracket_spec` is an optional argument that is the pair of control characters for the open and close array brackets. For example, `'[]'` indicates that each rank of the array is enclosed in square brackets. The default definition comes from the `OPEN_ARRAY` and `CLOSE_ARRAY` characters of the data pipeline. Valid options are: `''`, `'[]'`, `'{}'`, `'()'`, and `'<>'`. | | |
| `TRANSFORM(T[], (T) -> U)` | Transforms an array based on the logic in a lambda expression. The first argument is an expression that evaluates to an | ARRAY<br><br>Lambda Function `(x) -> U` or Reference Function | Elements of the array transformed to the return value and type of the anonymous function. | `TRANSFORM($data mes[], (el CHAR > LOWER(el)) as lower_case_name ray`<br>`TRANSFORM($data mes[], LOWER) a` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
| --- | --- | --- | --- | --- |
| | array that contains the elements to transform. The second argument is a lambda expression (or reference function) that defines how to transform each element.<br>`TRANSFORM` returns an array of elements of the same length as the array argument of the type returned by the lambda function.<br>The second argument must be of the form `(x T) -> U`. This returns a value of type `U` for a specified element `x`. The type `T` of the element `x` is specified in the lambda function.<br>The second argument can also be a reference function for a single argument function.<br>For supported options and examples, see **Special Data Pipeline Transformation Functions**. | | | `lower_case_name ray` |
| `WIDTH_BUCKET(X,min ,max,N)` | Creates `N` equal-width buckets in the range `[min,max)` as a histogram. If `X` is less than `min`, | `X` is the value for bucket determination.<br><br>`min` is the minimum value for | Integer | `WIDTH_BUCKET('$ 1, 5, 2) AS output` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
| --- | --- | --- | --- | --- |
| | then the function returns 0. If `X` is greater than or equal to the value of `max`, the function returns `N+1` buckets. If `X` is less than the value of `max` and greater than or equal to the value of `min`, the function returns the number of the bucket corresponding to where the input value belongs in the histogram. The values are inclusive on the lower bound and exclusive on the upper bound, so all buckets are the same width. Requesting 100 buckets retrieves 102 possible buckets, bucket 0 through 101, where 0 captures all values below the minimum and 101 captures all values at the maximum and beyond. | the histogram.<br><br>`max` is the maximum value for the histogram.<br><br>`N` is the number of buckets in the histogram. | | |
| `ZIP_WITH(array1, ..., array2, func)` | Merges two or more input arrays, element-wise, into a single array using the trailing combining function. If one array is shorter than the others, the system appends `NULL` | ARRAY<br><br>ARRAY<br><br>Lambda Function `(x T, y U) -> V` or Reference Function | An array of length `max(length(array1), length(array2))` containing elements of type `V` as returned by the lambda function. | `ZIP_WITH($line_ms[].product_na $line_items[].s (name CHAR, sku CHAR) -> concat(name, '[ sku, ']'))` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
| --- | --- | --- | --- | --- |
| | values at the end to match the length of the longest array before applying. Returns an `array` with elements that result from applying the function `func` to each pair of elements from `array1` and `array2`. If the arrays are not the same length, the system pads the shorter array with `NULL` values. `func` must be of the form `(x T, y U) -> V`, where `x` is the element from `array1` and `y` is the element from `array2`. Types `T` and `U` are specified in the lambda function.<br>For supported options and examples, see **Special Data Pipeline Transformation Functions**. | | | |

## Date and Time Transformation Functions

Date and time transformation functions provide utilities to parse, convert, or transform `DATE`, `TIME`, and `TIMESTAMP` values in pipelines.

| Name | Description | Supported Input Type | Return Type | Example SEI Expression |
| --- | --- | --- | --- | --- |
| `DATE(X)` | If the input type is a `CHAR`, the `DATE` function parses the string into a `DATE` type according to the format `YYYY[-/]MM[-/]DD...`. The format is in this order:<br>4-digit year<br>dash or backlash<br>2-digit month<br>a dash or backslash<br>2-digit day<br>any number of trailing characters<br><br>If the input type is a `TIMESTAMP`, the function parses the date portion of the timestamp (in UTC) into a `DATE` type. | CHAR<br>TIMESTAMP | DATE | CSV:<br>`DATE($24) as date_col`<br>`DATE(TIMESTA)) as date_c`<br>JSON:<br>`DATE($a.b.c) date_col`<br>`DATE(TIMESTAb.c)) as dat` |
| `TO_DATE(X,F,FT)` | Converts the specified value to a DATE.<br>`X` — The value to convert.<br>`F` — (optional) The format string for the interpretation of the textual representation of `X`.<br>`FT` — (optional) The format type. There are two format types: `ocient` and `java`. If you use the `ocient` type, the function uses the Ocient-based formatting function to parse the date. For details, see **TO_DATE**. If you use the `java` type, the function uses the `DateTimeFormatter` | CHAR | DATE | `to_date($3, 'YYYY/MM/DD'`<br>`to_date($a.b 'DD.MM.YYYY'` |

| Name | Description | Supported Input Type | Return Type | Example SEI Expression |
| --- | --- | --- | --- | --- |
| | in Java® to parse the timestamp. For details, see **DateTimeFormatter (Java Platform SE 8 )**.<br><br>The default is the `ocient` format type with format string `YYYY-MM-DD`. If you specify the `java` format type, you must specify a valid `DateTimeFormatter` format string, as there is no default. | | | |
| `INT_TO_DATE(arg)` | Creates a `DATE` type from an `INT` type representing the number of days after the Unix® epoch (January 1, 1970). | INT | DATE | `INT_TO_DATE( col_date_1` |
| `TIME(X)` | If the input type is a `CHAR`, the `TIME` function parses the string into a `TIME` according to the format `HH:MI[:SS[.NS]]`. The format is a 2-digit hour between 00 and 23, a colon, a 2-digit minute, an optional colon and 2-digit second, and an optional period and 1-9 digits for fractional seconds. The value can end optionally in `Z` to denote UTC (Zulu). The value can also end optionally in `±TZH[:TZM]` to denote the timezone offset. This format is a plus or minus sign, a 2-digit hour, and an | CHAR<br>BIGINT<br>TIMESTAMP | TIME | CSV: `TIME($34) as time_col` `TIME(BIGINT( as time_col` JSON: `TIME($a.b.c) time_col` `TIME(BIGINT( ) as time_co` |

| Name | Description | Supported Input Type | Return Type | Example SEI Expression |
| --- | --- | --- | --- | --- |
| | function uses the Ocient-based formatting function to parse the timestamp. For details, see **TO_TIMESTAMP**. If you use the `java` type, the function uses the `DateTimeFormatter` in Java to parse the timestamp. For details, see **DateTimeFormatter (Java Platform SE 8 )**.<br><br>The default is the `ocient` format type with format string `YYYY-MM-DD HH:MI:SS` . If you specify the `java` format type, you must specify a valid `DateTimeFormatter` format string, as there is no default. | | | |
| `SECONDS_TO_TIMESTAMP(X)` | Converts the specified value to a TIMESTAMP.<br>This function creates a TIMESTAMP from a BIGINT that represents the number of nanoseconds after the Unix epoch (January 1, 1970). | BIGINT | TIMESTAMP | CSV: `SECONDS_TO_TIMESTAMP($35) as timestamp_co`<br>JSON: `SECONDS_TO_TIMESTAMP($a.b.c) a timestamp_co NANOS_TO_TIM (bigint(1651 123456789)) 2022-05-04T16:29:48` |
| `MILLIS_TO_TIMESTAMP(X)` | Converts the specified value to a TIMESTAMP.<br>This function creates a TIMESTAMP from a BIGINT that represents the | BIGINT | TIMESTAMP | `MILLIS_TO_TIMESTAMP($35) as timestamp_co` |

| Name | Description | Supported Input Type | Return Type | Example SEI Expression |
|---|---|---|---|---|
| | number of milliseconds after the Unix epoch (January 1, 1970).<br>Alias for `TIMESTAMP(X)` where `X` is the `BIGINT` type. | | | |
| `MICROS_TO_TIMESTAMP(X)` | Converts the specified value to a TIMESTAMP.<br>This function creates a TIMESTAMP from a BIGINT that represents the number of microseconds after the Unix epoch (January 1, 1970). | BIGINT | TIMESTAMP | `MICROS_TO_TIP($35) as timestamp_co` |
| `NANOS_TO_TIMESTAMP(X)` | Converts the specified value to a TIMESTAMP.<br>This function creates a TIMESTAMP from a BIGINT that represents the number of nanoseconds after the Unix epoch (January 1, 1970). | BIGINT | TIMESTAMP | CSV: `NANOS_TO_TIM($35) as timestamp_co`<br>JSON: `NANOS_TO_TIM($a.b.c) as timestamp_co`<br>`NANOS_TO_TIM(bigint(1651123456789))`<br>`2022-05-04T16:29:48.789` |
| `NOW()` | Returns the current TIMESTAMP. | | TIMESTAMP | `now() as col_load_timp` |

For the TO_TIMESTAMP function, the Ocient formatter currently does not support variable-length sections of timestamps (i.e., the data might have a different number of fractions of seconds across records).

For example, assume this source data.

```
2024-01-01 12:00:00.123456
```

```
2024-01-01 12:00:00.1234
```

Then, you must specify the `format_type` as `java` and enter the `DateTimeFormatter` format string to parse the timestamps.

## Character Data Transformation Functions

Character data transformation functions operate on `VARCHAR` data to transform a string of data.

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| `CONCAT(arg1, arg2[, ...])` | Returns a string that is the result of concatenating the arguments provided. Accepts two or more arguments to concatenate. If one of the arguments to `CONCAT` is `NULL`, then `CONCAT` returns `NULL`. ℹ `CONCAT` does not support `HASH` or `BINARY` arguments in loading. | `arg1` : CHAR `arg2` : CHAR `arg3` ... `argN` (optional) CHAR | CHAR | `CONCAT($1, $2)` `CONCAT(TRIM($fi _name), '_', TRIM($last_name` |
| `SUBSTRING(X, P, L)` | Extract a substring from `X` beginning at the position offset `P` with a length `L`. `X` is the source data in CHAR or BINARY data type. `P` is the numeric | `X` : CHAR or BINARY `P` : INT `L` : INT | Return type matches the type of `X` : * CHAR * BINARY | `substring($orde ostcode, 1, 5)` `col_postcode` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
| --- | --- | --- | --- | --- |
| | byte position in the record that starts at index 1, which indicates the position to begin reading. `L` is the length of data to return starting from position `P`. For `VARCHAR` data, by default, the Ocient System treats each byte in a source field reference (e.g., `$your_field`) as an ASCII-encoded character, not multi-byte character data. To handle multi-byte character data such as UTF-8 in a source field, you must cast `X` as `CHAR($your_field)` or use another function that returns `CHAR` data. `P` and `L` represent the character offset and the number of characters to retrieve from the source data. | | | |
| `TRIM(arg1[, arg2])` `BTRIM(arg1[, arg2])` | Trims the leading and trailing space characters (or optionally, characters specified in the `arg2` argument) from the `arg1` argument. | `arg1`: CHAR `arg2` ( optional) must be a CHAR of length 1. | CHAR | `TRIM('__testTri nction__', '_')` `'testTrimFuncti '` `BTRIM(' testBtrimFuncti ') ->` `'testBtrimFunct '` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| `REPLACE(arg1, arg2, arg3)` | The `arg1` argument is the input string for the replace operation. The `arg2` argument is the pattern to replace or the target string. The `arg3` argument is the pattern for the replacement or the replacement string. This function replaces occurrences of `arg2` in `arg1` with `arg3` . | `arg1` : CHAR `arg2` : CHAR `arg3` : CHAR | CHAR | `REPLACE('testRe ceFunctionXYZ', 'X', 'Z') -> 'testReplaceFun onZYZ'` |
| `LENGTH(arg1)` `CHAR_LENGTH(arg1)` `CHARACTER_LENGTH(a rg1)` | These functions perform the same operation of returning the character length of the input string. `arg1` is the input string. ⚠ When you use these functions with the `SUBSTRING` , `RIGHT` , or `LEFT` function, you might experience unintended results for multi-byte characters, such as Arabic in UTF-8 if you do not cast the field reference to `CHAR` . | CHAR | INT | `LENGTH('hello world') -> 11` |
| `UPPER(arg1)` `UCASE(arg1)` | Converts the characters in the input string to all uppercase characters. | CHAR | CHAR | `UPPER('Hello there') -> 'HEL THERE'` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| `LOWER(arg1)` `LCASE(arg1)` | Converts the characters in the input string to all lowercase characters | CHAR | CHAR | `LOWER('Obi Wan Kenobi') -> 'ob wan kenobi'` |
| `LOCATE(arg1, arg2[, arg3])` `POSITION(arg1, arg2[, arg3])` | Returns the index position of the first occurrence of the character value `arg1` in character value `arg2`. Optionally, you can also include `arg3` to offset the search by the specified number of spaces. | `arg1` : CHAR `arg2` : CHAR `arg3` : LONG | INT | `LOCATE('F', 'testLocateFunc n') -> 11` `POSITION('on', 'testPositionFu ion', 12) -> 19` |
| `LEFT(arg1, arg2)` | Returns the number of characters in the `arg1` string equal to the `arg2` integer value. If the integer is negative, the function returns all characters except the last number of characters as specified by the `arg2` value. This function treats source field references (e.g., `$your_field`) as single-byte ASCII characters by default, similar to the `SUBSTRING` function. | `arg1` : CHAR `arg2` : LONG | CHAR | `LEFT('testLeftF tion', 4) -> 'test'` `LEFT('testLeftF tion', -4) -> 'testLeftFunc'` |
| `RIGHT(arg1, arg2)` | Returns the number of trailing characters in the `arg1` string equal to the `arg2` integer value. If the integer is | `arg1` : CHAR `arg2` : LONG | CHAR | `RIGHT('green te 3) -> 'tea'` `RIGHT('coffee beans', -7) -> 'beans` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
| --- | --- | --- | --- | --- |
| | negative, the function returns all characters except the first number of characters as specified by the `arg2` value. This function treats source field references (e.g., `$your_field`) as single-byte ASCII characters by default, similar to the `SUBSTRING` function. | | | |
| `TO_CHAR(value, format)` | Converts the binary value specified by `value` into a character value by performing an encode or decoding using the format value specified by `format`. | `value` — BINARY(N) or VARBINARY<br><br>`format` — CHAR with these supported values:<br><br>`'hex'` — Encodes into a hexadecimal string with no `0x` prefix and lowercase letters.<br><br>`'base64'` — Encodes into a `base64` string with padding. This encoding is not URL-safe and does not include line breaks.<br><br>`'char'` — Decodes into a string with the specified `CHAR` encoding, which can be values such as: `'utf-8'`, `'utf-16le'`, | CHAR | `TO_CHAR(BINARY('6f6369656e74'), 'hex') -> '6f6369656e74'`<br><br>`TO_CHAR(BINARY('6f6369656e74'), 'utf-8') -> 'ocient'` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| | | `'utf-16be'`, or `iso-8859-1`. | | |
| `HEX(value)` | Alias for `TO_CHAR(value, 'hex')` | `value` — BINARY(N) or VARBINARY | CHAR | `HEX(BINARY('0x6 69656e74')) -> '6f6369656e74'` |
| `TO_HASH(value, length, format)` | Converts the string value specified by `value` into a fixed length binary value with length specified by `length` by encoding or decoding using the format value specified by `format`. | `value` — CHAR<br><br>`length` — INT<br><br>`format` — CHAR with these supported values:<br><br>`'hex'` — Decodes from a hexadecimal string with optional `0x` prefix and case-insensitivity.<br><br>`'base64'` — Decodes from a `base64` string with optional padding. This decoding is not URL-safe and does not expect line breaks.<br><br>`char` — Encodes into a string with the specified `CHAR` encoding, which can be values such as: `'utf-8'`, `'utf-16le'`, `'utf-16be'`, or `iso-8859-1`. | HASH(arg2) | `TO_HASH('6f6369 e74', 6, 'hex') 0x6f6369656e74`<br><br>`TO_HASH('ocient 6, 'utf-8') -> 0x6f6369656e74` |
| `TO_VARBINARY(value, format)` | Converts the string value specified by `value` into a variable length binary value by encoding or decoding using the | See `TO_HASH` description. | VARBINARY | `TO_VARBINARY('6 69656e74', 'hex -> 0x6f6369656e`<br><br>`TO_VARBINARY('o nt', 'utf-8') - 0x6f6369656e74` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| | format value specified by `format`. | | | |
| `UNHEX(value)` | Alias for `TO_VARBINARY(value, 'hex')` | `value`: CHAR | VARBINARY | `UNHEX('6f6369654') -> 0x6f6369656e74` |

> ⚠ When you use the SUBSTRING, RIGHT, and LEFT functions with Delimited or JSON formatted data sources, the Ocient System does not treat a source field reference (e.g., `$your_field`) as multi-byte character data. Each byte is treated as a single-byte ASCII character. To handle multi-byte character data like UTF-8 in a source field, you must cast the source field using `CHAR($your_field)` or use another function that returns `CHAR` data.
>
> When you use the LENGTH, CHAR_LENGTH, and CHARACTER_LENGTH functions with the SUBSTRING, RIGHT, and LEFT functions, you might experience unintended results for multi-byte characters, such as Arabic in UTF-8 if you do not cast the source field reference to `CHAR`.

## Binary Data Transformation Functions

Binary data transformation functions operate on bytes provided when you use the `BINARY` format type in a pipeline. These functions are typically used in processing mainframe data outputs.

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| `FLOAT(bytes [, endianness])` | With a byte array in the `BINARY` format, parse bytes in standard IEEE® 754 `binary32` (single-precision) format. | `bytes` is a 4-byte array extracted from BINARY data.<br><br>`endianness` (optional) must be a literal string. Valid values include `'big'` and `'little'`. The default value is the `ENDIANNESS` option in the pipeline definition. | FLOAT | BINARY: `FLOAT($"[5, 4]" as float_col1`<br>`FLOAT($"[5, 4]" 'little') as float_col2` |
| `DOUBLE(bytes [, endianness])` | With a byte array in the `BINARY` | `bytes` is an 8-byte array | DOUBLE | BINARY: `DOUBLE(FLOAT($"` |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| | format, parse bytes in standard IEEE 754 `binary64` (double-precision) format. | extracted from BINARY data.<br><br>`endianness` (optional) must be a literal string. Valid values include `'big'` and `'little'`. The default value is the `ENDIANNESS` option in the pipeline definition. | | `8]")) as double_col1` `DOUBLE($"[5, 8] 'big') as double_col2` |
| `TINYINT(bytes [[, signed], endianness])` | Converts a 1-byte array that represents a signed or unsigned number to the `TINYINT` format. ⚠ If you do not specify the correct number of bytes or if an unsigned transform overflows a signed target column, the function throws an error. | `bytes` is a single-byte array extracted from BINARY data.<br><br>`signed` is a string literal that indicates if the bytes represent a signed or unsigned `BINARY` format. Valid values include `'signed'` and `'unsigned'`. The default value is `'signed'`.<br><br>`endianness` is a string literal that indicates whether the bytes are in the big or little endian format. Valid values include `'big'` and `'little'`. The default value is the `ENDIANNESS` option in the pipeline definition. | TINYINT | BINARY: `TINYINT($"[9, 1 as tiny_1` `TINYINT($"[9, 1 'unsigned') as tiny_2` `TINYINT($"[9, 1 'signed', 'little') as tiny_3` |
| `SMALLINT(bytes [[, signed], endianness])` | Converts a 2-byte array that represents a signed or unsigned number to the | `bytes` is a 2-byte array extracted from BINARY data.<br><br>`signed` is a string | SMALLINT | BINARY: `SMALLINT($"[9, 2]") as small_1` `SMALLINT($"[9, 2]", 'unsigned'` |

| --- | --- | --- | --- | --- |
| | | two digits per byte) and `'zoned'` (meaning the array contains decimal data in each nibble for one digit per byte).<br><br>`precision` is the total number of significant digits.<br><br>`scale` is the number of digits after the decimal point.<br><br>`sign_format` is a string literal that indicates how the transformation should extract sign information from the bytes. Valid values include `'leading'` (means that the system stores the sign in the upper nibble of the first byte for both `'zoned'` and `'packed'` data formats), `'leading_separate'` (means the system stores the sign as a separate new first byte from the digit data), `'trailing'` (means that the system stores the sign in the upper nibble of the last byte when the data format is set to `'zoned'` and in | | |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| | | the lower nibble of the last byte when set to `'packed'`), or `'trailing_separate'` (means the system stores the sign as a separate new last byte from the digit data). For `'leading'` and `'trailing'` sign information, accepted sign values are `0x7`, `0xB`, and `0xD` for negative signs and `0xA`, `0xC`, `0xE`, and `0xF` for positive. The accepted sign values for `'leading_separate'` and `'trailing_separate'` sign information are `0x2D` for `-` negative signs and `0x2B` for `+` positive. The default value for `sign_format` is `'trailing'` for both `format` data formats. | | |

## Array Data Transformation Functions

| Name | Description | Supported Input Type | Return Type | Example SELE Expression |
|---|---|---|---|---|
| `ARRAY_CAP(A,N)` | Restrict the length of an array to a maximum number of elements. | `A` is an array of any type.<br><br>`N` is the maximum number | Array of any type | `ARRAY_CAP(A, 1000)` |

| Name | Description | Supported Input Type | Return Type | Example SELE Expression |
|---|---|---|---|---|
| | | of elements for the length of the specified array. | | |
| `ARRAY_COMPACT(array)` | Removes NULL values from the array. | `array` is an array that contains any type of elements. The array can be single or multi-dimensional. | Array of any type | `ARRAY_COMPACT(s[])` |
| `ARRAY_CONTAINS(array, value)` | Returns `true` if the array contains the specified value.<br><br>If the specified value is NULL, then this transform function returns NULL. | `array` is an array that contains any type of elements. The array can be single or multi-dimensional.<br><br>`value` is an integer. | Boolean or NULL | `ARRAY_CONTAINS(ts[], 1)` |
| `ARRAY_DISTINCT(array)` | Return all unique values in an array. For details, see **ARRAY_DISTINCT**. | `array` is an array that contains any type of elements. The array can be single or multi-dimensional. | Array of any type | `ARRAY_DISTINCT(ts[])` |
| `ARRAY_LENGTH(array,dim)` | Returns the length of the array for the specified dimension `dim`, which starts at index 1.<br><br>If you specify a dimension that is greater than the size of the array, the function returns NULL. | `array` is an array that contains any type of elements. The array can be single or multi-dimensional.<br><br>`dim` is an integer. | Integer | With `$arr` containing `[[1,2,3],[4,5,6]]`, `ARRAY_LENGTH($a 2)` returns `3` the second dimension of the array. |
| `ARRAY_SORT(array)`<br><br>`ARRAY_SORT(array,function)` | `ARRAY_SORT(array)` sorts and returns the input array based on the natural ordering of its elements.<br><br>If one of the array | For the first syntax, `array` is an array of elements with these types: `BIGINT`, `BOOLEAN`, `BYTE`, `DATE`, `DOUBLE`, | Array of any type | `ARRAY_SORT($"1c [], (x int, y i -> CASE WHEN x THEN 0 WHEN INT(COALESCE(x, 1000)) < INT(COALESCE(y, 1000)) THEN -1` |

| Name | Description | Supported Input Type | Return Type | Example SELE( Expression |
|---|---|---|---|---|
| | elements is NULL, then this transform function sorts the NULL values to the end of the array.<br><br>`ARRAY_SORT(array, function)` sorts and returns the input array based on the results of the specified Lambda function.<br><br>The function should have two arguments representing two elements of the array. This function should return a negative integer, 0, or a positive integer if the first element is less than, equal to, or greater than the second element, respectively.<br><br>For details, see **ARRAY_SORT**. | `FLOAT`, `INT`, `SMALLINT`, `UUID`, or `VARCHAR`.<br><br>For the second syntax, `array` is an array that contains any type of elements. The array can be single or multi-dimensional. The `function` argument is a Lambda function with the format `(x T, y T) -> INT` or another SQL reference function. | | `ELSE 1 END)` sc the array in `1d` column using th Lambda functior with a CASE statement. The CASE statement returns 0 when x and y are equal, returns -1 when integer cast of tl non-NULL value less than the corresponding value for y, and returns 1 otherw |
| `ELEMENT_AT(array,I )` | Returns the element value of the array or tuple at the specified index. You can specify a negative index value as long as the absolute value of the index does not exceed the length of the array or tuple. If the index is out of bounds, the function returns NULL. | `array` is an array or tuple.<br><br>`I` is a 1-based index, specified as an integer. | Any type. | `$a` accesses th array `[1,2,3]`.<br><br>`ELEMENT_AT($a,1` returns `1`.<br><br>`ELEMENT_AT($a,-` returns `3`.<br><br>`ELEMENT_AT($a,-` returns `2`.<br><br>`ELEMENT_AT($a,-` returns NULL. |

| Name | Description | Supported Input Type | Return Type | Example SELE Expression |
|---|---|---|---|---|
| `FLATTEN(array)` | Transforms an `N` -dimensional array into an `N-1` -dimensional array.<br><br>If one of the inner array elements is NULL, this transform function returns NULL. | `array` is a multi-dimensional array, for example `T[][]` , that contains any type of elements. | Array of any type that can be single or multi-dimensional. | `FLATTEN($ints[][])` |
| `REDUCE(array, start_value, merge_function, finish_function)` | Applies a merge function to a starting value and all elements in the array, and then reduces the array to a single value. Optionally, specify a finish function for the returned single value.<br><br>The function applies the merge function to each element of the array with the start value to return a final value. | `array` is an array of any type and can be a single or multi-dimensional array.<br><br>`start_value` is the starting value of any type.<br><br>`merge_function` is a Lambda function or any reference function. This Lambda function has the form `(x U, y T) -> U` .<br><br>`finish_function` is a Lambda function or any reference function. This Lambda function has the form `(x U) -> V` . | This function returns the value of type `V` , which can be any type, from the finish function.<br><br>If you do not specify the finish function, this function returns the type `U` , which can be any type, from the merge function. | Assuming `ints[` is `INT[]` of `[1, 2, 3]` , `REDUCE($ints[], (acc int, x int > acc + x)` returns the valu `6` .<br><br>Assuming `ints[` is `INT[]` of `[1, 2, 3]` , `REDUCE($ints[], (acc int, x int > acc + x, BOOLEAN)` returns the `tru` value. In this cas the finish functio is the BOOLEAN reference functi with the input va being the resulti value from the merge function: `BOOLEAN(6)` . |
| `TO_ARRAY_LENGTH(V, N)` | Create the specified number of copies of any JSON object in an array. | `V` is any JSON object to copy into the result array.<br><br>`N` is the number of copies to make in the result array. | Array of any type | `TO_ARRAY_LENGTH 3)` |

## Logical Operations Transformation Functions

These transformation functions execute logical operations on the data in the data pipeline.

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| `IF(X,T,F)` | Returns `T` if the expression `X` evaluates to `true`, or the function returns `F` if `X` evaluates to `false`. `IF` and `IFF` are function aliases. | Any type | Any type | `IF('$2', '1', ' AS output` |
| `CASE WHEN expression1 THEN result1 WHEN expression2 THEN result2 ... ELSE result END` | Returns the `result` value based on whether an expression is `true`. If none of the expressions evaluate to `true`, then the function returns the `result` value after the `ELSE` keyword. | Any type | Any type | `CASE WHEN $x TH 'True was input in' ELSE 'False was input in' END A toutput` |
| `NULL_IF(X, Y)` | Returns the `NULL` value if the two input arguments are equal. If the arguments are not equal, the function returns `X`. | Any type | Any type | `INT(NULL_IF($32 '')) INT(NULL_IF($a. , ''))` |

## Network Type Functions

Network type functions are also supported in loading. For example, `SUBNET(IP($9),13) AS ipv6_subnet_form1` in the `CREATE PIPELINE SELECT` SQL statement converts the input data in the column to an IPv6-mapped IPv4 address and then computes the prefix of size 13 for that address. For the supported network type functions, see **Network Type Functions**.

## Other Data Transformation Functions

Other data transformation functions include the extraction of values from the JSON format and miscellaneous functions such as `COALESCE`, which are commonly used when working with data pipelines.

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| `COALESCE(arg1, arg2)` | Returns `arg1` if it is non-NULL; otherwise, the function returns `arg2`.<br><br>`arg1` and `arg2` can be any data type, but their types must match. | Any type | Matches `arg1` and `arg2` type | `COALESCE($1, $2` `COALESCE(int($1` `int($2))` `COALESCE(bigint` `), 13)` `COALESCE(substr` `(char($1), 1, 2` `TRIM($2))` |
| `JSON_EXTRACT_PATH_TEXT(X, D)` | Extracts a value from a JSON string. | `X` is the JSON string for extracting a value in `CHAR` type.<br><br>`D` is the key of the value to extract in `CHAR` type. | CHAR | `JSON_EXTRACT_PA` `TEXT(JSON_UNESC` `($real_field_ke` `'b') AS col_cha` |
| `MAP_KEYS(X)` | Returns the keys in the specified JSON string. | `X` is the JSON string. | ARRAY OF STRINGS | Input JSON string `a` : `'{"name":"John"` `"age":30,` `"car":null}'`<br><br>`MAP_KEYS($a)`<br><br>Output: `["age", "car",` `"name"]` |
| `MAP_VALUES(X)` | Returns the values in the specified JSON string. | `X` is the JSON string. | ARRAY OF STRINGS | Input JSON string `a` : `'{"name":"John"` `"age":30,` `"car":null}'`<br><br>`MAP_VALUES($a)`<br><br>Output: |

| Name | Description | Supported Input Type | Return Type | Example SELEC Expression |
|---|---|---|---|---|
| | | | | `["John", "30", null]` |

## DEFAULT Keyword

You can use the `DEFAULT` keyword to include the configured default value of a column in transformation functions.

### Example

SQL

```
COALESCE($my_field, DEFAULT) as my_column
```

## Lambda Functions

Lambda functions are a transformative tool in data pipelines, enabling declarative and highly flexible data transformations. By supporting per-element operations on arrays and nested data structures, lambda functions streamline data ingestion and reduce the need for post-processing. Their adoption enables you to handle complex, real-time data engineering scenarios natively.

Lambda functions enable you to apply custom logic to each element of an array during ingestion. They support advanced operations like filtering and aggregation. You can embed transformation logic directly in the pipeline definition. This embedding reduces the need for additional processing steps after the load.

| Expression | Description |
|---|---|
| **Lambda Function Expression**<br>(T1,...,Tn) -> U | A lambda function is a temporary function that takes 0 or more named arguments as a parenthesis-enclosed list and returns an expression. The expression can reference objects defined within the closure of the expression, which includes locally named arguments that are locally defined within an enclosing scope, field references, literals, etc.<br>For examples, see **Special Data Pipeline Transformation Functions**. |

| Expression | Description |
| --- | --- |
| **Reference Function Expression**<br>UPCASE = UPCASE(x) -> CHAR<br>tuple = tuple(T1,...,Tn) -> tuple<<T1,...,Tn>> | A reference function points to an existing function in the Ocient function list. Specifying the function name allows you to use that function in contexts where you would otherwise need to create a full lambda function. For examples, see **Special Data Pipeline Transformation Functions**. |

## User-Defined Data Pipeline Functions

You can create a user-defined data pipeline function using the `CREATE PIPELINE FUNCTION` SQL statement and Groovy. After you create data pipeline functions, you can execute them in data pipelines like any other function to transform records.

For more details, see **CREATE PIPELINE FUNCTION** and **Data Types for User-Defined Data Pipeline Functions**.

# Special Data Pipeline Transformation Functions

The Data Pipeline functionality allows data transformation during loading using SQL functions like `EXPLODE_OUTER`, which expands arrays into individual rows.

When you load data in the Ocient® System, you can use special loading transformation functions in the `SELECT` SQL statement to transform the data on load.

## EXPLODE_OUTER

`EXPLODE_OUTER` expands a one-dimensional or multidimensional array into its elements with one element per row of output from the system. The array can contain a maximum of 8,192 elements, which is the limit for the default settings.

The function takes an array of rank `N` and expands the elements, returning elements of rank `N-1`. For example, when you apply `EXPLODE_OUTER` to an array of integers, the system returns each integer in its own row. When you apply `EXPLODE_OUTER` to an array of arrays of integers, the system returns each array of integers in its own row. You can add further transforms to these elements by nesting the statement, e.g., `NANOS_TO_TIMESTAMP(EXPLODE_OUTER($int_array_field[]))`.

You can use this function with multiple columns in the same table. The system holds constant columns that are not expanded. Also, the system combines expanded columns together in array order. If multiple expanded columns have different array lengths, the system expands the record into `N` records where `N` is the maximum length. Columns with array lengths less than `N` have NULL values after the system expands each value.

### Limitations

- When you use this function with multi-dimensional arrays, you cannot apply it multiple times to match the number of dimensions, for example.
- Each record must have an associated 64-bit record number, which uniquely identifies a row within its partition. Configure the format of this number using the `RECORD_NUMBER_FORMAT` advanced pipeline option to modify the maximum number of elements that the array to expand can contain. For details, see **Advanced Pipeline Tuning Options**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- The system uses record numbers for deduplication, so changing the `RECORD_NUMBER_FORMAT` option of a pipeline can change its deduplication behavior. Always create a new pipeline when you change this option to make rows deduplicate properly.
- To make rows deduplicate properly when you do not set this option, always create a new pipeline when adding an `EXPLODE_OUTER` statement to your pipeline or removing all such statements from your pipeline.

### Syntax

SQL

```
EXPLODE_OUTER(array)
```

| Argument | Data Type | Description |
|---|---|---|
| `array` | Array | An array to expand. |

### Example

Create the `test_table` table to load data with three columns where the first two columns are integers, and the third is a string.

SQL

```
CREATE TABLE test_table (
    "i" INT NULL,
    "j" INT NULL,
    "v" VARCHAR(536870912) COMPRESSION DYNAMIC NULL );
```

Preview the load using this inline source data in JSON format: `{"id": 1, "int_array": [1, 2, 3], "string_array": ["a", "b"]}`. Use the `EXPLODE_OUTER` function to expand the elements of the arrays in the second and third JSON data values.

SQL

```
PREVIEW PIPELINE p1
SOURCE INLINE
    '{"id": 1, "int_array": [1, 2, 3], "string_array": ["a", "b"]}'
EXTRACT FORMAT json
INTO test_table
SELECT $"id" as i,
    EXPLODE_OUTER($"int_array"[]) as j,
    EXPLODE_OUTER($"string_array"[]) as v;
```

*Output*

Text

```
i j v
------------------------------------------------------------------
1 1 a
1 2 b
1 3 NULL
Fetched 3 rows
```

The output shows that the inline array values are expanded across the individual rows.

## Special Functions for Array Transformations in Pipelines

The data pipeline functionality supports special transformation functions for arrays that use lambda functions or function expressions to apply SQL operations to individual elements in an array.

The supported special functions are:

- `FILTER` — Filter the elements in an array. Apply a filter function to each element in an array and return an array of elements matching the filter function.
- `TRANSFORM` — Transform individual elements in an array. Apply a transformation expression to every element in the array.
- `ZIP_WITH` — Combines multiple arrays using a zipping function. Apply a zipping function to `N`-wise pairs of elements from `N` arrays and return an array with the

results from the zipping function.

Each of these functions takes one or more arrays as input arguments and a lambda or other reference function for applying to the elements in the array. A lambda function is an anonymous function that must have a specific signature and return type for the array transformation function where you use the lambda function.

> `ARRAY_TRANSFORM`, `ARRAY_TRANSFORM_WITH_ORD`, and `ZIP_WITH_ORD` also transform arrays using a lambda function or reference function, but they are standard SQL functions rather than data pipeline transformation functions. For details, see **ARRAY_TRANSFORM**, **ARRAY_TRANSFORM_WITH_ORD**, and **ZIP_WITH_ORD** in **Array Functions and Operators**.

## FILTER

Filters elements in an array based on the logic in a lambda expression. The first argument is an expression that evaluates to an array that contains the elements to filter. The second argument is a lambda expression or reference function that returns `true` if the system should retain the element in the returned array.

The second argument must be of the form `(x T) -> BOOL`. This form returns a specified value for the specified element `x`. The lambda function specifies the type `T` of the element `x`.

The `FILTER` function includes elements in the first argument array in the resulting array when the lambda function returns `true`. Otherwise, the function excludes the elements.

### Syntax

SQL

```
FILTER(array, function)
```

| Argument | Data Type | Description |
|---|---|---|
| `array` | Array | The array can be single or multi-dimensional. The `FILTER` function only iterates over the first dimension. |
| `function` | Reference function<br>or<br>Lambda function | A function that takes an element of type `T` and returns a `BOOL`.<br>The function can be a lambda function (e.g., `(elem CHAR)` |

| Argument | Data Type | Description |
| --- | --- | --- |
| | `(x T) -> BOOL` | `-> length(elem) > 10` ) or a function name that has the correct argument list (e.g., `UPPER` ). |

### Example

With the specified data in the pipeline source record `{ "data": { "names": ["Jane", "Charles", "Kim"] }}` , filter the names in the input array for elements that are greater than five characters long using the Lambda function `(name CHAR) -> length(name) > 5` . The example focuses on the `SELECT` statement and does not show the rest of the data pipeline definition.

SQL

```
CREATE PIPELINE
...
SELECT
    FILTER($data.names[], (name CHAR) -> length(name) > 5) as long_names
```

*Output: * `["Charles"]`

## TRANSFORM

Transforms an array based on the logic in a lambda function. The first argument is an expression that evaluates to an array that contains the elements to transform. The second argument is a lambda function or other reference function that defines how to transform each element.

The second argument must be of the form `(x T) -> U` . This specified form returns a value of type `U` for a specified element `x` . The lambda function specifies the type `T` of the element `x` .

The second argument can also be another reference function for a single argument function.

The `TRANSFORM` function returns an array of elements with the same length as the array argument. The returned array has the type returned by the lambda function. For multi-dimensional arrays, the `TRANSFORM` function applies to the outermost dimension. You can nest `TRANSFORM` functions to apply them over inner dimensions.

© 2026 Ocient, Inc

## Syntax

```
SQL

TRANSFORM(array, function)
```

| Argument | Data Type | Description |
|---|---|---|
| `array` | Array | The array can be single or multi-dimensional. The `TRANSFORM` function only iterates over the first dimension. |
| `function` | Lambda function `(x T) -> U` or Reference function | A lambda function (e.g., `(elem CHAR) -> LEFT(elem, 2)`) that takes an element of type `T` and returns a value of type `U`, which can be the same type as `T` or a different type, or a reference function with the correct argument list (e.g., `UPPER`). |

## Examples

### Extract the First Initial from Array Elements Using a Lambda Function

Create the `first_initial_test` table to load data with one array column.

```
SQL

CREATE TABLE first_initial_test (
    first_initial_array VARCHAR[] );
```

Preview the load using this inline source data in JSON format: `{ "payload": { "names": ["Jane", "Charles", "Kim"] }}`. Use the `TRANSFORM` function with the lambda function `(el CHAR) -> LEFT(el,1)` to return the first character of each element in the input array `$payload.names[]`.

```sql
PREVIEW PIPELINE p_first_initial
SOURCE INLINE
    '{ "payload": { "names": ["Jane", "Charles", "Kim"] }}'
EXTRACT FORMAT json
INTO first_initial_test
SELECT
    TRANSFORM($payload.names[], (el CHAR) -> LEFT(el,1)) as first_initial_array;
```

Output: `["J", "C", "K"]`

### Convert All Array Elements to Lowercase Using a Reference Function

Create the `lower_case_test` table to load data with one array column.

```sql
CREATE TABLE lower_case_test (
    lower_case_name_array VARCHAR[] );
```

Preview the load using this inline source data in JSON format: `{ "payload": { "names": ["Jane", "Joe", "Jill"] }}`. Use the `TRANSFORM` function with the `LOWER` reference function to convert the input strings in `$payload.names[]` to lowercase.

```sql
PREVIEW PIPELINE p_lower_case
SOURCE INLINE
    '{ "payload": { "names": ["Jane", "Joe", "Jill"] }}'
EXTRACT FORMAT json
INTO lower_case_test
SELECT
    TRANSFORM($payload.names[], LOWER) as lower_case_name_array;
```

Output: `["jane", "joe", "jill"]`

## ZIP_WITH

Merges two or more input arrays, element-wise, into a single array using the trailing combining function. If one array is shorter than the other, the function appends NULLs at the end to match the length of the longest array at the start.

Returns an `array` with elements that result from applying the function to each pair of elements from `array1` and `array2`. If the arrays are not the same length, the function pads the shorter array with NULL values. The function returns an array of length `max(length(array1), length(array2))` containing elements of type `V` as returned by the lambda function.

`function` must be of the form `(x T, y U) -> V` where `x` is the element from `array1` and `y` is the element from `array2`. The lambda function specifies the types `T` and `U`. When zipping more arrays together, use the format `(x T1, y T2, z T3) -> V` where the arguments to the lambda function align with the order of the input arrays of the `ZIP_WITH` function.

### Syntax

SQL

```
ZIP_WITH(array1, array2 [, ...], function)
```

| Argument | Data Type | Description |
|---|---|---|
| `array1` | Array | The array can be single or multi-dimensional. The `ZIP_WITH` function only iterates over the first dimension. |
| `array2` | Array | The array can be single or multi-dimensional. The `ZIP_WITH` function only iterates over the first dimension. |
| `function` | Lambda function `(x T) -> BOOL` or Reference function | A function that takes an element of type `T` and returns a `BOOL`. The function can be a lambda function (e.g., `(elem CHAR) -> length(elem) > 10`) or a function name that has the correct argument list (e.g., `UPPER`). |

### Example

With the specified data in the pipeline source record `{ "line_items": [{ "product_name": "suede shoes", "sku": "FT-1023-BLU" }, { "product_name": "cheap sunglasses", "sku": "ZZ-7821-K" }] }`, concatenate the product name `$line_items[].product_name` strings

with the SKU `$line_items[].sku` strings as the format `"name(sku)"`. The example focuses on the `SELECT` statement and does not show the rest of the data pipeline definition.

SQL

```
CREATE PIPELINE
...
SELECT ZIP_WITH(
  $line_items[].product_name, $line_items[].sku,
  (name CHAR, sku CHAR) -> concat(name, '(', sku, ')')
)
```

*Output: * `["suede shoes (FT-1023-BLU)", "cheap sunglasses (ZZ-7821-K)"]`

## Lambda Functions

A lambda function is a temporary function that takes zero or more named arguments as a parenthesis-enclosed list and returns an expression. The expression can reference objects defined within the closure of the expression, which includes locally named arguments that are locally defined within an enclosing scope, field references, literals, and so on.

### Syntax

Define lambda functions using this syntax where `T1` represents an element of type `T1` and `U` represents the return type of the function.

SQL

```
(T1,...,Tn) -> U
```

When you use this function in a SQL statement, the syntax requires an argument name and the explicit designation of the type of each argument, but the return type `U` can be inferred. For example, define a lambda function that accepts two arguments of type `CHAR` and `INT` named `x` and `y`, respectively.

SQL

```
(x CHAR, y INT) -> LEFT(x, y)
```

© 2026 Ocient, Inc

### Examples

#### String Manipulation Using a Lambda Function

Convert `x` to uppercase and return the first character.

```SQL
(x CHAR) -> LEFT(UPCASE(x),1)
```

#### Concatenate Using a Lambda Function

Concatenate two strings (e.g., first and last name) with a space between them.

```SQL
(x CHAR, y CHAR) -> CONCAT(x, ' ', y)
```

## Reference Functions

A reference function points to an existing function in the Ocient function list. Specifying the function name allows you to use that function in contexts where you would otherwise need to create a full lambda function.

The signature of the function must match the argument structure and return value requirements.

### Examples

The reference function `UPCASE` is equivalent to the lambda function `(x CHAR) -> UPCASE(x)` because the syntax of `UPCASE` accepts one argument of type `CHAR` and returns a value of type `CHAR`.

Use the `UPCASE` function with the `TRANSFORM` function to capitalize all names in an array. These two SQL statements are equivalent.

```
TRANSFORM($names[], UPCASE)
```

```
TRANSFORM($names[], (n CHAR) -> UPCASE(n))
```

# Data Types for User-Defined Data Pipeline Functions

Reference for Java packages and classes used in Ocient user-defined data pipeline functions, including column type enumerations and array and tuple definitions.

This description provides the Ocient® packages that support the functionality for user-defined data pipeline functions.

## Classes

### `com.ocient.streaming.schema.OcientColumnType`

The class that enumerates all defined column types in the Ocient System.

| Enum Value |
| --- |
| `TYPE_NONE` |
| `TYPE_INFERRED` |
| `TYPE_DELETED` |
| `TYPE_INT` |
| `TYPE_BIGINT` |
| `TYPE_FLOAT` |
| `TYPE_DOUBLE` |
| `TYPE_VARCHAR` |
| `TYPE_IPV4` |
| `TYPE_TIMESTAMP` |
| `TYPE_DATE` |
| `TYPE_BOOLEAN` |
| `TYPE_BINARY` |
| `TYPE_SMALLINT` |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Enum Value |
| --- |
| `TYPE_BYTE` |
| `TYPE_UUID` |
| `TYPE_HASH` |
| `TYPE_IP` |
| `TYPE_ST_POINT` |
| `TYPE_TIME` |
| `TYPE_DECIMAL` |
| `TYPE_ARRAY` |
| `TYPE_TUPLE` |
| `TYPE_ST_LINESTRING` |
| `TYPE_ST_POLYGON` |

## `com.ocient.streaming.schema.OcientColumnTypeArguments`

The class that describes arguments of a column type. Not all column types require arguments.

| Modifier And Type | Field and Description |
| --- | --- |
| `public static final OcientColumnTypeArguments` | `NONE` — A default instance indicating no arguments are necessary for a column type. |

## `com.ocient.streaming.schema.OcientColumnTypeArguments.Decimal`

A subclass of `OcientColumnTypeArguments` that includes information for `TYPE_DECIMAL`.

| Modifier And Type | Field and Description |
| --- | --- |
| `public int` | `precision` — The number of digits in a number. |
| `public int` | `scale` — The number of digits to the right of the decimal point in a number. |
| `public boolean` | `fullFormat` — True if the serialized format includes one byte for precision and one byte for scale. You should always set this to `true`. |

### Constructor

| |
|---|
| `public Decimal(int precision, int scale, boolean fullFormat)` Constructs a newly allocated `OcientColumnTypeArguments` for `OcientColumnType.TYPE_DECIMAL`. |

## com.ocient.streaming.schema.OcientColumnTypeArguments.Hash

A subclass of `OcientColumnTypeArguments` that includes information for `TYPE_HASH`.

| Modifier And Type | Field and Description |
|---|---|
| `public int` | `length` — The number of bytes in the hash value. |

### Constructor

| |
|---|
| `public Hash(int length)` — Constructs a newly allocated `OcientColumnTypeArguments` for `OcientColumnType.TYPE_HASH`. |

## com.ocient.streaming.schema.OcientColumnTypeArguments.Array

A subclass of `OcientColumnTypeArguments` that includes information for `TYPE_ARRAY`.

| Modifier And Type | Field and Description |
|---|---|
| `public OcientColumnType` | `elementType` — The array element type. |
| `public OcientColumnTypeArguments` | `elementTypeArguments` — Type arguments for the array element type. |

### Constructor

| |
|---|
| `public Array(OcientColumnType elementType)` — Constructs a newly allocated `OcientColumnTypeArguments` for an array of `elementType`. The `elementTypeArguments` field initializes to `OcientColumnTypeArguments.NONE`. |
| `public Array(OcientColumnType elementType, OcientColumnTypeArguments elementTypeArguments, int offsetSizeOverride)` — Constructs a newly allocated `OcientColumnTypeArguments` for an array of `elementType`. You should set `offsetOverride` to `0`. |

## com.ocient.streaming.schema.OcientColumnTypeArguments.TopLevelTuple

A subclass of tuple that includes information for top-level tuples.

| Modifier And Type | Field and Description |
| --- | --- |
| `private List<OcientColumn>` | `elementOcientColumns` — List of tuple element types. |

| Modifier And Type | Method and Description |
| --- | --- |
| `public List<OcientColumnTypeArguments>` | `getTupleTypeArguments()` — Returns the list of tuple element type arguments. |
| `public List<OcientColumnType>` | `getTupleTypes()` — Returns the list of tuple element types. |
| `public List<OcientColumn>` | `getElementOcientColumns()` — Returns the list of tuple element types paired with their arguments. |

**Constructor**

`public TopLevelTuple(List<OcientColumn> elementOcientColumns)` — Constructs a newly allocated `OcientColumnTypeArguments` for a `OcientColumnType.TYPE_TUPLE`.

## `com.ocient.streaming.schema.OcientColumn`

Represents an Ocient column with information parsed from metadata of the Ocient System.

| Modifier And Type | Method and Description |
| --- | --- |
| `public String` | `name()` — The name of the column. |
| `public OcientColumnType` | `type()` — The data type of the column. |
| `public OcientColumnTypeArguments` | `typeArguments()` — Some column types, for example `Decimal`, have arguments that are required to fully understand their format. A relevant subclass of `OcientColumnTypeArguments` returns, as appropriate, or `OcientColumnTypeArguments.NONE`. |
| `public boolean` | `required()` — Returns `true` if the user is required to provide this column. This is generally the case for non-defaulted, non-nullable columns. |
| `public boolean` | `nullable()` — Returns true if this column is configured as nullable, false otherwise. |

## com.ocient.streaming.data.types.gis.Coordinate

Represents a two-dimensional cartesian coordinate.

| Modifier And Type | Field and Description |
|---|---|
| `public double` | `x` — The x coordinate of the point. |
| `public double` | `y` — The y coordinate of the point. |

| Modifier And Type | Method and Description |
|---|---|
| `public double` | `x()` — Returns the x coordinate of this point. |
| `public double` | `y()` — Returns the y coordinate of this point. |

**Constructor**

| |
|---|
| `public Coordinate(double x, double y)` — Constructs a newly allocated Coordinate. |

## com.ocient.streaming.data.types.gis.STPoint

Represents a two-dimensional cartesian coordinate.

| Modifier And Type | Field and Description |
|---|---|
| `public Coordinate` | `coordinate` — The ordered, x and y coordinate pair. |

| Modifier And Type | Method and Description |
|---|---|
| `public static STPoint` | `fromWKT(String text)` — Parses an `STPoint` from the WKT text. |
| `public static STPoint` | `fromEWKT(String text)` — Parses an `STPoint` from the EWKT text. |
| `public double` | `getX()` — Returns the x coordinate of this point. |
| `public double` | `getY()` — Returns the y coordinate of this point. |
| `public STLinestring` | `toLinestring()` — Promotes the `STPoint` to an `STLinestring` container. Useful when representing a geometry collection consisting of `STLinestring` and `STPoint` elements. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Modifier And Type | Method and Description |
| --- | --- |
| `public STPolygon` | `toPolygon()` — Promotes the `STPoint` to an `STPolygon` container. Useful when representing a geometry collection consisting of any geospatial element type. |

### Constructor

| |
| --- |
| `public STPoint(Coordinate coordinate)` — Constructs a newly allocated `STPoint`. |

## com.ocient.streaming.data.types.gis.STLinestring

Geometric type that is composed of a sequence of N points.

| Modifier And Type | Field and Description |
| --- | --- |
| `public STPoint[]` | `points` — The ordered sequence of points in the linestring. |

| Modifier And Type | Method and Description |
| --- | --- |
| `public static STLinestring` | `fromWKT(String text)` — Parses an `STLinestring` from the WKT text. |
| `public static STLinestring` | `fromEWKT(String text)` — Parses an `STLinestring` from the EWKT text. |
| `public STPoint[]` | `points()` — Returns the points of this linestring. |
| `public STLinestring` | `toLinestring()` — Returns `this`. |
| `public STPolygon` | `toPolygon()` — Promotes the `STLinestring` to an `STPolygon` container. Useful when representing a geometry collection consisting of any geospatial element type. |

### Constructor

| |
| --- |
| `public STLinestring(STPoint[] points)` — Constructs a newly allocated `STLinestring`. |

## com.ocient.streaming.data.types.gis.STPolygon

Geometric type composed of N closed linestrings.

| Modifier And Type | Field and Description |
| --- | --- |
| `public STLinestring` | `exteriorRing` — The exterior ring of the polygon. |
| `public STLinestring[]` | `interiorRings` — The interior rings of the polygon. |

| Modifier And Type | Method and Description |
| --- | --- |
| `public static STLinestring` | `fromWKT(String text)` — Parses an `STPolygon` from the WKT text. |
| `public static STLinestring` | `fromEWKT(String text)` — Parses an `STPolygon` from the EWKT text. |
| `public STLinestring` | `exteriorRing()` — Returns the exterior linestring. |
| `public STLinestring[]` | `interiorRings()` — Returns the interior linestrings. |
| `public STPolygon` | `toPolygon()` — Returns `this`. |

**Constructor**

`public STPolygon(STLinestring exteriorRing, STLinestring[] interiorRings)` — Constructs a newly allocated `STPolygon`.

## `com.ocient.streaming.data.types.Timestamp`

Timestamp represented as nanoseconds from the Unix® epoch.

| Modifier And Type | Method and Description |
| --- | --- |
| `public long` | `value()` — Returns the number of nanoseconds after the Unix epoch. |

**Constructor**

`public Timestamp(long nanosFromEpoch)` — Constructs a newly allocated `Timestamp`.

## `com.ocient.streaming.data.types.Time`

Time that is represented as nanoseconds from midnight ( `00:00:00` ).

© 2026 Ocient, Inc

| Modifier And Type | Method and Description |
| --- | --- |
| `public long` | `value()` — Returns the number of nanoseconds after midnight. |

**Constructor**

| |
| --- |
| `public Time(long nanosFromMidnight)` — Constructs a newly allocated `Time`. |

## `com.ocient.streaming.data.types.Decimal`

A class representing a decimal number with binary-coded decimal (BCD) storage, supporting specified precision and scale.

| Modifier And Type | Field and Description |
| --- | --- |
| `public static long` | `MAX_PRECISION` — The maximum supported precision in the database. |

| Modifier And Type | Method and Description |
| --- | --- |
| `public static Decimal` | `fromString(String s, byte precision, byte scale)`<br>Creates a `Decimal` object from a string representation with the specified precision and scale.<br>• `s` — The string representation of the decimal (e.g., `"123.45"`, `"-0.1"`).<br>• `precision` — The precision (total number of digits) of the decimal.<br>• `scale` — The scale (number of digits after the decimal point) of the decimal. |
| `public static Decimal` | `fromBigDecimal(java.math.BigDecimal d, byte precision, byte scale)`<br>Creates a `Decimal` object from a `BigDecimal`, ensuring compatibility with the specified precision and scale.<br>• `d` — The `BigDecimal` to convert.<br>• `precision` — The precision (total number of digits) of the decimal.<br>• `scale` — The scale (number of digits after the decimal point) of the decimal. |
| `public static Decimal` | `fromDouble(double d, byte precision, byte scale)`<br>Creates a `Decimal` object from a double value with the specified precision and scale.<br>• `d` — The double to convert. |

| Modifier And Type | Method and Description |
| --- | --- |
| | • `precision` — The precision (total number of digits) of the decimal.<br>• `scale` — The scale (number of digits after the decimal point) of the decimal. |
| `public String` | `toString()` — Returns the `Decimal` string representation of this `Decimal`. |
| `public long` | `asLong()` — Converts this `Decimal` object to a long, truncating any fractional part. |
| `public double` | `asDouble()` — Converts this `Decimal` object to a double, preserving the full value including the fractional part. |
| `public byte[]` | `bcd()` — Returns the BCD representation of this `Decimal` object. |
| `public byte[]` | `getFullFormat()` — Returns the full format representation, including precision and scale bytes followed by the BCD data padded to `MAX_PRECISION`. |
| `public int` | `precision()` — Returns the precision of this `Decimal` object. |
| `public int` | `scale()` — Returns the scale of this `Decimal` object. |

## `com.ocient.streaming.data.types.OcientTuple`

A class representing a tuple with a defined schema of column types and associated values. Supports fixed-length and variable-length elements.

| Modifier And Type | Method and Description |
| --- | --- |
| `public int` | `numValues()` — Returns the number of values currently stored in this tuple. |
| `public void` | `setValue(int index, Object value)`<br>Sets or updates the value at the specified index, ensuring type compatibility.<br>• `index` — The index of the value to set (0-based).<br>• `value` — The value to set must match the column type at the index. |
| `public void` | `set(List<Object> values)`<br>Sets or resets all values in the tuple from the provided list.<br>• `values` — The list of values to set must match the schema size and types. |

| Modifier And Type | Method and Description |
| --- | --- |
| `public String` | `toString()` — Returns a string representation of this tuple, including its schema and values (e.g., `"TUPLE<INT,DOUBLE>(1,2.0)"` ). |
| `public List<Object>` | `get()` — Returns the list of values in this tuple, in order. |
| `public List<OcientColumnType>` | `getTypes()` — Returns the list of column types defining the schema of this tuple, in order. |
| `public List<OcientColumnTypeArguments>` | `getTypeArgs()` — Returns the list of type arguments corresponding to the column types of this tuple, in order. |

### Constructor

`public OcientTuple(List<OcientColumnType> types, List<OcientColumnTypeArguments> typeArgs)`
Constructs an empty tuple with the specified schema of column types and type arguments.

- `types` — The list of column types defining the tuple schema.
- `typeArgs` — The list of type arguments corresponding to each column type.

**CREATE OR REPLACE PIPELINE FUNCTION**

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# Load Geospatial Data in Data Pipelines

Load geospatial data into Ocient with data pipelines using OcientGeo functions such as ST_POINT, ST_LINESTRING, and ST_POLYGON for spatial analytics.

Data pipeline loading supports the load of geospatial data for use with OcientGeo™ functionality in the OcientAIQ™ Unified Data Platform. Use geospatial functions to manipulate this data. For details, see **Geospatial Functions**.

## Supported Geospatial Functions

These geospatial functions are supported for data pipeline loading:

- **ST_FORCECCW**
- **ST_POINT** or **ST_MAKEPOINT**
- **ST_POINTFROMTEXT**
- **ST_POINTFROMEWKT**
- **ST_LINESTRING**
- **ST_LINEFROMTEXT**
- **ST_MAKELINE**
- **ST_LINEFROMEWKT**
- **ST_POLYGON(char)**
- **ST_POLYGON(geo)**
- **ST_POLYGON** or **ST_MAKEPOLYGON**
- **ST_POLYGONFROMTEXT**
- **ST_POLYGONFROMEWKT**

## Data Pipeline Loading of Geospatial Data Considerations

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### Auto-Casting Behavior of Source Data Types

The Ocient® System automatically casts geospatial data from the `CHAR` type to `POINT`, `LINESTRING`, or `POLYGON` types using the **ST_POINTFROMTEXT**, **ST_LINEFROMTEXT**, or **ST_POLYGONFROMTEXT** functions, respectively. The data must be in WKT format for the casting to work. If your data is not in the WKT format, use one of the supported geospatial functions to transform your data to the required type.

### Point Data Normalization During Data Pipeline Loading

During loading, the Ocient System automatically performs normalization of point data into a regular format used within Ocient. The Ocient System performs these operations on point data during the load:

- Constrain longitude to [-180, 180] and latitude to [-90, 90].
- Wrap around invalid coordinates using correct geographical handling.
- Snap points near the pole to the pole.
- Set the longitude of points on the pole to 0.
- Remove signed zeros from coordinates, so -0 becomes 0.

### Polygon Rotation Convention

The Ocient System has a standardized polygon orientation convention. The standard convention has the polygon with a counterclockwise rotation of the outer polygon ring and a clockwise rotation of the inner polygon ring. Use the **ST_FORCECCW** function to convert polygons to the standardized convention from systems that interpret polygon rotation differently.

### Size Limit for Geospatial Data Types

The maximum allowed size of geospatial data types is 512 MiB.

## Examples of Loading Geospatial Data

Use these examples to understand how to create a data pipeline to load geospatial data for different formats (point and WKT data).

## Load Geospatial Data Using Point Data

Create the target table `cities` using the `CREATE TABLE` SQL statement with these columns:

- `id` — Integer
- `name` — Variable-length string
- `location` — Numeric point

SQL

```
CREATE TABLE cities (
    id INT,
    name VARCHAR,
    location ST_POINT
);
```

Create the `cities` data pipeline using the `CREATE PIPELINE` SQL statement for an Amazon® Web Services℠ (AWS℠) S3 source with bucket `ocient-docs`, filter for the folder `metabase_samples/jsonl/cities.jsonl`, and region `us-east-1`. Use the JSON format to load a JSON file into the `cities` table. Specify a numeric point using the **ST_POINT** function with the longitude and latitude coordinates.

SQL

```
CREATE PIPELINE cities
    SOURCE S3
        BUCKET 'ocient-docs'
        FILTER 'metabase_samples/jsonl/cities.jsonl'
        REGION 'us-east-1'
    EXTRACT
        FORMAT json
INTO cities
SELECT
    $id AS id,
    $name AS name,
    ST_POINT($longitude, $latitude) AS location;
```

## Load Geospatial Data in WKT Format

Create the target table `geospatial_table` using the `CREATE TABLE` SQL statement with these non-nullable columns:

- `ts` — TimeKey® with daily time bucket as a timestamp
- `row_number` — Variable-length string
- `point` — POINT object
- `linestring` — LINESTRING object
- `polygon` — POLYGON object

SQL

```
CREATE TABLE geospatial_table(
    ts TIMESTAMP TIME KEY BUCKET(1, DAY) NOT NULL,
    row_number INT NOT NULL,
    point ST_POINT NOT NULL,
    linestring ST_LINESTRING NOT NULL,
    polygon ST_POLYGON NOT NULL
);
```

Create the `geospatial_pipeline` data pipeline using the `CREATE PIPELINE` SQL statement for an S3 source with bucket `ocient-docs`, filter for the folder `gis_small/gis_types/*.csv`, and region `us-east-1`. Use the CSV format to load a CSV file into the `geospatial_table` table. The file contains geospatial data in WKT format in the sixth, ninth, and twelfth columns with POLYGON, LINESTRING, and POINT data, respectively. Specify the polygon data in WKT format by using the **ST_POLYGONFROMTEXT** function and then reorient the resulting polygon counter-clockwise for the exterior and clockwise for the interior by using the **ST_FORCECCW** function.

During the load, the Ocient System automatically casts the WKT-formatted data in the three columns to the corresponding geospatial data types.

SQL

```
CREATE PIPELINE geospatial_pipeline
    SOURCE s3
        BUCKET 'ocient-docs'
        FILTER 'gis_small/gis_types/*.csv'
        REGION 'us-east-1'
    EXTRACT
        FORMAT csv
INTO geospatial_table
SELECT
    $1 AS ts,
    $2 AS row_number,
    $12 AS point,
    $9 AS linestring,
    ST_FORCECCW(ST_POLYGONFROMTEXT($6)) AS polygon;
```

# Load Data with a User-Defined Data Pipeline Function

Load data into Ocient with user-defined data pipeline functions written in Java to handle custom source formats, transformations, and business logic.

The data pipeline functionality in the Ocient® System enables you to transform data during loading. You can create your own data pipeline function to perform a custom transformation or calculation.

This example uses a user-defined data pipeline function to load weather data for Chicago. The function converts temperatures from Fahrenheit to Celsius. The formula for the conversion is `°C = (°F - 32) × 5/9`. The precipitation type data is an array with zero or more values in lowercase. The data pipeline also utilizes a lambda function to convert the first character of each precipitation type to uppercase. The pipeline uses the metadata `filename` in the data load as an audit trail.

## Retrieve the Weather Data from the Source

Retrieve year-to-date weather data for Chicago in JSON format from the **Weather Query Builder**. Here is a sample row of data. The data contains:

- `queryCost` — Cost of the query
- `latitude` — Latitude of the location
- `longitude` — Longitude of the location
- `resolvedAddress` — Address of the location with the country
- `address` — City and state of the address
- `timezone` — Time zone of the location
- `tzoffset` — Time zone offset
- `name` — Name of the location
- `days` — Daily weather data in an array with these fields:
  - `datetime` — Date of the weather data

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- `datetimeEpoch` — Date epoch of the weather data
- `tempmax` — Maximum temperature of the day
- `tempmin` — Minimum temperature of the day
- `temp` — Temperature of the day
- `feelslike` — Feels like temperature of the day
- `humidity` — Humidity for the day
- `precip` — Precipitation amount for the day
- `precipprob` — Probability of precipitation for the day
- `preciptype` — Type of precipitation for the day (array of strings for types such as rain, snow, and so on)
- `windspeed` — Wind speed for the day

JSON

```
{
    "queryCost" : 212,
    "latitude" : 41.8843,
    "longitude" : -87.6324,
    "resolvedAddress" : "Chicago, IL, United States",
    "address" : "chicago, il",
    "timezone" : "America/Chicago",
    "tzoffset" : -6.0,
    "name" : "chicago, il",
    "days" : [ {
        "datetime" : "2025-01-01",
        "datetimeEpoch" : 1735711200,
        "tempmax" : 35.3,
        "tempmin" : 24.8,
        "temp" : 30.0,
        "feelslike" : 19.5,
        "humidity" : 63.9,
        "precip" : 0.037,
        "precipprob" : 100.0,
        "preciptype" : [ "rain", "snow" ],
        "windspeed" : 17.6
    } ]
}
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Create the `chicago_weather_ytd` table with these columns:

- `latitude` — Latitude of the location
- `longitude` — Longitude of the location
- `location_name` — Name of the location
- `log_date` — Date of the weather event
- `temp` — Temperature of the day
- `preciptype` — An array of characters for multiple types of weather events
- `file_name` — Name of the file that contains the weather data

SQL

```
CREATE TABLE chicago_weather_ytd(
    "latitude" double,
    "longitude" double,
    "location_name" varchar(20),
    "log_date" date,
    "temp" double,
    "preciptype" varchar(100)[],
    "file_name" varchar(500));
```

## Create a User-Defined Function for Temperature Conversion

Create a user-defined function that converts a degree value from Fahrenheit to Celsius, and round the returned value to one decimal place. Use Apache® Groovy™ code to specify the calculation and rounding.

SQL

```
CREATE PIPELINE FUNCTION f_to_c(f_value DOUBLE NOT NULL)
    LANGUAGE GROOVY
    RETURNS DOUBLE NOT NULL
    IMPORTS []
    AS $$
        return (10 * ((f_value - 32.0) * 5.0 / 9.0)).toInteger() / 10
    $$;
```

© 2026 Ocient, Inc

# Create a Data Pipeline to Load the Weather Data

Build a pipeline by using a preview of the data to load with the `PREVIEW PIPELINE` SQL statement to see how a limited number of rows loads. Preview four rows. Specify the JSON format. Transform the latitude and longitude to the double type using the `DOUBLE` cast function. For the date of the weather of the event `log_date`, expand the input array of days into its elements using the `EXPLODE_OUTER` function and convert the date to a `date` type using the `DATE` cast function. For the temperature of the day, expand the input array of days into its elements using the `EXPLODE_OUTER` function and convert the temperature to the double type using the `DOUBLE` cast function. Execute the `f_to_c` user-defined function to convert the temperature from Fahrenheit to Celsius. For the type of precipitation, expand the input array of days into its elements using the `EXPLODE_OUTER` function. Then, transform each element of the input array using a lambda function that converts the first character of the precipitation type to uppercase. Use the `METADATA` function to capture the filename.

SQL

```
PREVIEW PIPELINE chicago_weather_ytd_pipeline
SOURCE filesystem
    FILTER '/tmp/data/json_files/nested_json/Chicago_Weather_Daily_YTD.json'
    LIMIT 4
EXTRACT FORMAT json
INTO chicago_weather_ytd
SELECT DOUBLE($latitude) AS latitude,
    DOUBLE($longitude) AS longitude,
    $address AS location_name,
    DATE(EXPLODE_OUTER($days[].datetime)) AS log_date,
    f_to_c(DOUBLE(EXPLODE_OUTER($days[].temp))) AS temp,
    EXPLODE_OUTER(TRANSFORM($days[].preciptype[],
        (x VARCHAR) -> CONCAT(UPPER(SUBSTRING(x,1,1)),SUBSTRING(x,2,20)))) AS pre
    METADATA('filename') AS file_name;
```

Output

Text

```
latitude              longitude             location_name
-------------------------------------------------------------------------------
41.8843               -87.6324              chicago, il
41.8843               -87.6324              chicago, il
41.8843               -87.6324              chicago, il
41.8843               -87.6324              chicago, il
```

Create the data pipeline by replacing `PREVIEW` with the `CREATE` keyword in the SQL statement.

SQL

```
CREATE PIPELINE chicago_weather_ytd_pipeline
SOURCE filesystem
FILTER '/tmp/data/json_files/nested_json/Chicago_Weather_Daily_YTD.json'
EXTRACT FORMAT json
INTO chicago_weather_ytd
SELECT DOUBLE($latitude) AS latitude,
    DOUBLE($longitude) AS longitude,
    $address AS location_name,
    DATE(EXPLODE_OUTER($days[].datetime)) AS log_date,
    f_to_c(DOUBLE(EXPLODE_OUTER($days[].temp))) AS temp,
    EXPLODE_OUTER(TRANSFORM($days[].preciptype[],
        (x VARCHAR) -> CONCAT(UPPER(SUBSTRING(x,1,1)),SUBSTRING(x,2,20)))) AS pre
    METADATA('filename') AS file_name;
```

## Execute the Data Pipeline Load

Start the data pipeline by allowing 100 errors before the pipeline fails. The data pipeline runs to completion.

SQL

```
START PIPELINE chicago_weather_ytd_pipeline ERROR LIMIT 100;
```

Use the `SHOW PIPELINE_STATUS` command to view the status of the data pipeline.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SHOW PIPELINE_STATUS;
```

Output

Text

```
database_name|pipeline_name      |table_names                              |status    |
-------------+-------------------+-----------------------------------------+----------+
training     |chicago_weather_ytd|{'admin@system.chicago_weather_ytd'}|COMPLETED|
training     |city_weather       |{'admin@system.city_weather'}       |COMPLETED|
training     |counties_load      |{'admin@system.us_counties'}        |COMPLETED|
```

Display five rows of the loaded data sorted by the date of the weather event.

SQL

```
SELECT *
FROM chicago_weather_ytd
LIMIT 5
ORDER BY log_date;
```

Text

```
latitude|longitude|location_name|log_date  |temp|preciptype     |file_name
--------+---------+-------------+----------+----+---------------+---------------
 41.8843| -87.6324|chicago, il  |2025-01-01|-1.1|{'Rain','Snow'}|/tmp/data/json_t
 41.8843| -87.6324|chicago, il  |2025-01-02|-2.1|{'Rain','Snow'}|/tmp/data/json_t
 41.8843| -87.6324|chicago, il  |2025-01-03|-4.6|{'Snow'}       |/tmp/data/json_t
 41.8843| -87.6324|chicago, il  |2025-01-04|-7.2|NULL           |/tmp/data/json_t
 41.8843| -87.6324|chicago, il  |2025-01-05|-6.4|{'Snow'}       |/tmp/data/json_t
```

## Load Metadata and File-Based Partitioned Data in Data Pipelines

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# Load Data from External Sources in Data Pipelines

Use the LOOKUP keyword and LOOKUP function in CREATE PIPELINE statements to enrich data loads in Ocient by joining records with external source tables.

The data pipeline functionality in the Ocient® System enables you to load data from external sources, such as other databases, using the `LOOKUP` function and the `LOOKUP` keyword of the corresponding `CREATE PIPELINE` SQL statement. You must use the function and the `LOOKUP` keyword together to join data from an external source.

You can use the `LOOKUP` function with multiple external sources by specifying each source with its `LOOKUP` function and corresponding `LOOKUP` keyword syntax.

### Syntax

The `LOOKUP` function returns a value from an external source table based on a join between a specified value and another column in the source table. The function creates and executes this SQL statement from the specified function arguments.

SQL

```
SELECT return_column_name
FROM lookup_source_name
WHERE value = join_column_name;
```

The source table should only have unique values for the `join_column_name` column for the join operation.

SQL

```
LOOKUP(lookup_source_name, value, join_column_name, return_column_name)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `lookup_source_name` | VARCHAR | The name of the external source defined by the `LOOKUP` keyword in |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Argument | Data Type | Description |
| --- | --- | --- |
| | | the `CREATE PIPELINE` SQL statement. |
| `value` | VARCHAR, BOOLEAN, BYTE, SMALLINT, INT, BIGINT, FLOAT, DOUBLE, DATE, TIME, TIMESTAMP, HASH, BINARY, DECIMAL, UUID | The value for the lookup. |
| `join_column_name` | VARCHAR | The name of a column in the external source table for the join operation. |
| `return_column_name` | VARCHAR, BOOLEAN, BYTE, SMALLINT, INT, BIGINT, FLOAT, DOUBLE, DATE, TIME, TIMESTAMP, HASH, BINARY, DECIMAL, UUID | The name of the column in the external source table that contains the data to load. |

If the data type of the returned value of the `LOOKUP` function is not one of the data types specified for the `return_column_name` argument, then the function transforms the value to the nearest compatible type, typically `VARCHAR`.

### Example

Create a data pipeline `lookup_data_pipeline` that loads data from the CSV file `data.csv`. Use an external source `existing_all_types` with the table `tablename` in the schema `schemaname` using a JDBC connection with the connection string: `jdbc:host://111.1.1.1:4200/databasename;user=username@databasename;password=testpassword`. For your connection string, substitute these variables with the values specific to your database and credentials:

- `host` — Hostname
- `111.1.1.1` — IP address
- `4200` — Port number
- `databasename` — Database name
- `username` — Username
- `testpassword` — Password

Look up data in the `col_binary` column of the `tablename` table by joining the second column of the CSV file to the `col_bigint` column in the `tablename` table. Load the data in the `col_binary` column based on the result of the `LOOKUP` function.

SQL

```
CREATE PIPELINE lookup_data_pipeline
SOURCE FILESYSTEM
    FILTER '/tmp/folder/data.csv'

```

## Performance Considerations

The performance of the lookup operation depends on the size of the external source. If the external source is large, the lookup operation is slower. The Ocient System recommends keeping the size to less than five million rows for the total size of all external source tables used by actively running data pipelines in the system.

# Load Data into Multiple Targets in Data Pipelines

Use one Ocient data pipeline to load time-partitioned data from AWS S3 into multiple target tables in batches for parallel ingestion and routing.

A common setup for loading files in a batch into Ocient® is to load from a bucket on Amazon® Web Services℠ (AWS℠) S3 with time-partitioned data. Often, you must perform a batch load repeatedly to load new files.

Ocient uses data pipelines to transform each document into rows in one or more different tables. The loading and transformation capabilities use a simple SQL-like syntax for transforming data. This tutorial guides you through a load into multiple target tables using a small data set in CSV format. The data in this example comes from a test set for the Metabase℠ Business Intelligence tool.

## Prerequisites

This tutorial assumes that:

1. The Ocient System has network access to S3 from the Loader Nodes.
2. An Ocient System is installed and configured with an active Storage Cluster (see the **Ocient Application Configuration** guide).

## Step 1: Create a New Database

Connect to a SQL Node using the **Commands Supported by the Ocient JDBC CLI Program**. Then, execute the `CREATE DATABASE` SQL statement for a database named `metabase`.

SQL

```
CREATE DATABASE metabase;
```

## Step 2: Create Tables

© 2026 Ocient, Inc

Create two target tables for loading data for two different products.

Create the `product129` table in the new database. First, connect to that database (e.g., `connect to jdbc:ocient://sql-node:4050/metabase`), and then execute this `CREATE TABLE` SQL statement that specifies to create a table with these columns and a clustering index based on the `user_id` and `product_id` columns:

- `created_at` as a TimeKey® timestamp that is not nullable.
- `id`, `user_id`, and `product_id` as integers that are not nullable.
- `subtotal`, `tax`, `total`, and `discount` as floating point numbers.
- `quantity` as an integer.

SQL

```
CREATE TABLE public.product129 (
    created_at TIMESTAMP TIME KEY BUCKET(30, DAY) NOT NULL,
    id INT NOT NULL,
    user_id INT NOT NULL,
    product_id INT NOT NULL,
    subtotal DOUBLE,
    tax DOUBLE,
    total DOUBLE,
    discount DOUBLE,
    quantity INT,
    CLUSTERING INDEX idx01 (user_id, product_id)
);
```

Create the second `product161` table in the same way.

SQL

```sql
CREATE TABLE public.product161 (
    created_at TIMESTAMP TIME KEY BUCKET(30, DAY) NOT NULL,
    id INT NOT NULL,
    user_id INT NOT NULL,
    product_id INT NOT NULL,
    subtotal DOUBLE,
    tax DOUBLE,
    total DOUBLE,
    discount DOUBLE,
    quantity INT,
    CLUSTERING INDEX idx01 (user_id, product_id)
);
```

The database creates the `product129` and `product161` tables, and you can begin loading data.

## Step 3: Create a Data Pipeline

Create data pipelines using the `CREATE PIPELINE` SQL statement. To load data, you first create a pipeline with the definition of the source, data format, and transformation rules using a SQL-like declarative syntax. Then, you execute the `START PIPELINE` SQL statement to start the load. You can observe progress and status using system tables and views.

Each Ocient pipeline defines a single data source and the target table or tables into which data loads. A data source includes the location of the source and filters on the source to define the specific data set to load. This example loads data from a data source located in a directory within the S3 bucket.

First, inspect the data that you plan to load. Each document has a format similar to this example CSV file named `orders.csv`.

© 2026 Ocient, Inc

Text

```
id,user_id,product_id,subtotal,tax,total,discount,created_at,quantity
1,1,14,37.65,2.07,39.72,null,2019-02-11T21:40:27.892Z,2
2,1,123,110.93,6.1,117.03,null,2018-05-15T08:04:04.580Z,3
3,1,105,52.72,2.9,49.2,6.42,2019-12-06T22:22:48.544Z,2
...
```

In this case, Ocient automatically transforms the data to the target columns using some sensible conventions. In other cases, loads require some transformation. Most transformations are identical to functions that already exist in the SQL dialect of the Ocient System.

Create a pipeline named `orders_pipeline` for the orders data set from your database connection prompt. Use the S3 data source with endpoint `https://s3.us-east-1.amazonaws.com`, bucket `ocient-docs`, and filter `metabase_samples/csv/orders.csv`. Specify the CSV format with one header line. Load the data into the two target tables. The `SELECT` part of the SQL statement maps the fields in the CSV file to the target columns in the created table.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```sql
CREATE PIPELINE orders_pipeline
SOURCE
    S3
        ENDPOINT 'https://s3.us-east-1.amazonaws.com'
        BUCKET 'ocient-docs'
        FILTER 'metabase_samples/csv/orders.csv'
EXTRACT
    FORMAT csv
    NUM_HEADER_LINES 1
INTO public.product129
SELECT
    $1 as id,
    $2 as user_id,
    $3 as product_id,
    $4 as subtotal,
    $5 as tax,
    $6 as total,
    $7 as discount,
    $8 as created_at,
    $9 as quantity
WHERE $3 = 129

INTO public.product161
SELECT
    $1 as id,
    $2 as user_id,
    $3 as product_id,
    $4 as subtotal,
    $5 as tax,
    $6 as total,
    $7 as discount,
    $8 as created_at,
    $9 as quantity
WHERE $3 = 161;
```

The pipeline has three main sections:

- `SOURCE` — In this case, load data from S3. Specify the endpoint and bucket. The `FILTER` parameter identifies the file or files to load. The load uses a single CSV

file. Options exist to add wildcards or regular expressions to isolate different file sets.

- `EXTRACT` — Set the format to CSV files and note that there is one header line in the file. This specification skips that row when the Ocient System processes the file. Many other options exist for delimited data such as a record delimiter and field delimiter.
- `INTO ... SELECT` — Choose the target tables `public.product129` and `public.product161` and select the fields from the CSV file. The numeric index identifies each file field. Importantly, similar to other SQL syntax, the first field in the file is `$1`, not `$0`. Each field maps to a target column using the `as` syntax. The `WHERE` filter instructs the data pipeline to load order data for only two products, one product for each table.

After you successfully create the `orders_pipeline` pipeline, execute the `START PIPELINE` SQL statement.

SQL

```
START PIPELINE orders_pipeline;
```

## Step 4: Observe the Load Progress

With your pipeline running, data immediately begins to load from the S3 files that you defined. If there are many files in each file group, the load process first sorts the files into batches, partitions them for parallel processing, and assigns them to Loader Nodes.

You can check the pipeline status and progress by querying `information_schema.pipeline_status` or by executing `SHOW PIPELINE_STATUS`.

SQL

```
SHOW PIPELINE_STATUS;
```

*Output*

```
SQL

database_name          pipeline_name       table_names
-------------------------------------------------------------------------------
metabase               orders_pipeline     ["public.product129" "public.product161
```

After the status of the pipeline changes to `COMPLETED`, all data is available in the target table.

After a few seconds, the data is available for query in the `public.product129` table.

```
SQL

SELECT COUNT(*) FROM public.product129;
```

Output

```
SQL

count(*)
--------------------
93
```

The data is also available for query in the `public.product161` table.

```
SQL

SELECT COUNT(*) FROM public.product161;
```

Output

```
SQL

count(*)
--------------------
92
```

You can drop the pipeline with the `DROP PIPELINE orders_pipeline;` SQL statement. Execution of this statement leaves the data in your target table, but removes metadata about the pipeline execution from the system.

# Load metadata and partitioned data in data pipelines

Use the METADATA() function in Ocient data pipelines to extract file metadata such as filenames and creation timestamps from source records during loading.

The data pipeline loading infrastructure enables the loading of certain metadata values of a source record into the Ocient® System. Metadata represents information about a record that is not represented in the record data itself, e.g., the filename of the source record or the timestamp when a record was created in Apache® Kafka®. You can also load data in partitioned files using Apache® Hive™ naming standards with a filter set in the file path.

### Syntaxes

The `METADATA` function can load a variety of metadata along with each record of the data pipeline, or it can use key-value pairs to return the value in the filename metadata.

### Load Metadata into a Column

To load a metadata value into a column, use the `METADATA` function in the `SELECT` SQL statement and replace `key` with the key you want to load. You can use transformation functions to achieve the final data type or allow the pipeline to apply automatic casting.

SQL

```
METADATA(key)
```

| Argument | Data Type | Description |
|---|---|---|
| `key` | string | The name of the specified metadata key. Example: `'topic'` |

### Retrieve a Value from Filename Metadata

To retrieve a value from a key-value pair in the filename metadata, specify the first argument as `'hive_partition'` and provide a search string for the key. In this case, the

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

filename must follow Hive naming standards. The standard embeds field names and key-value pairs in path segments, such as `/year=2019/month=2/data.parquet`. If there are duplicate key-value pairs in the filename, the function uses the last pair. The function returns a string with the value of the associated key, and returns NULL if the file does not contain the search string or the filename does not follow Hive naming standards.

SQL

```
METADATA('hive_partition',search_string)
```

| Argument | Data Type | Description |
|---|---|---|
| `search_string` | string | The search string to use as a key for searching the filename metadata to return the value from the key-value pair as a string. |

Loads a variety of header metadata along with each record of the data pipeline.

SQL

```
METADATA('header', header_row_index, header_col_index)
```

| Argument | Data Type | Description |
|---|---|---|
| `header_row_index` | integer | The index, which starts at 1, of the header row to load. |
| `header_col_index` | integer | The index, which starts at 1, of the header column to load. |

⚠ Metadata fields cannot be combined in a transformation function with other source data.

### Supported Values for the Metadata Key

The metadata values you can load differ based on the source type. This table lists the available values for the metadata keys specified using the `key` argument by source type and their returned data type. Metadata key values are not case-sensitive.

| Metadata Key | Source Type | Returned Value Data Type | Description |
| --- | --- | --- | --- |
| `row_id` | File Load and Kafka Load | UUID | A unique row identifier that is generated by the Ocient System during loading. The Ocient System guarantees this identifier is unique for each loaded record because the generation is based on internal mechanisms that enforce record deduplication. |
| `filename` | File Load | VARCHAR | The filename and full file path indicate the source of the record. |
| `file_modified_time stamp` | File Load | TIMESTAMP | The timestamp that indicates when the file was last modified on the data source. |
| `header` | Delimited File Load | VARCHAR | Returns the string representation of the header field for the specified header row and column.<br><br>Returns NULL if any of these conditions exist:<br><br>The specified field is not present.<br><br>The specified field is empty, and the `EMPTY_FIELD_AS_NULL` delimited extract option is set to `true`.<br><br>The specified field matches one of the strings in the `NULL_STRINGS` delimited extract option. |
| `key` | Kafka Load | VARBINARY | The bytes of the Kafka key for the record. |
| `line_number` | File Load | BIGINT | The line number in the file for the source of the record. |
| `offset` | Kafka Load | BIGINT | The Kafka offset of the record. |
| `partition` | Kafka Load | BIGINT | The name of the Kafka partition that indicates the source of the record. |
| `record` | File and Kafka Load | VARCHAR | The string representation of the full record. For delimited, JSON, and binary formats, the system represents the record in the same way as the source. For XML, ASN.1, and Apache® Parquet™ formats, |

| Metadata Key | Source Type | Returned Value Data Type | Description |
|---|---|---|---|
| | | | the system represents the record as a JSON object. |
| `record_timestamp` | Kafka Load | TIMESTAMP | The timestamp that indicates when the record was created in the Kafka Broker. |
| `source_record_id` | File and Kafka Load | UUID | A unique source row identifier that is generated by the Ocient System during loading. The Ocient System guarantees this unique identifier for each source record with a specific SOURCE and EXTRACT configuration because the generation is based on source names, source record numbers, and source record offsets. |
| `topic` | Kafka Load | VARCHAR | The name of the Kafka topic that indicates the source of the record. |

## Examples

### Load Filename Metadata

This example snippet uses the `CREATE PIPELINE` SQL statement to load data and the source filename with each record in a pipeline. For details about this pipeline definition and setup, see **Data Pipeline Load of CSV Data from S3**.

SQL

```sql
CREATE PIPELINE orders_pipeline
SOURCE
    S3
        ENDPOINT 'https://s3.us-east-1.amazonaws.com'
        BUCKET 'ocient-docs'
        FILTER 'metabase_samples/csv/orders.csv'
EXTRACT
    FORMAT csv
    NUM_HEADER_LINES 1
INTO public.orders
SELECT
    $1 as id,
    $2 as user_id,
    $3 as product_id,
    $4 as subtotal,
    $5 as tax,
    $6 as total,
    $7 as discount,
    $8 as created_at,
    $9 as quantity,
    METADATA('filename') AS filename_column;
```

### Load Hive-Style Partitioned Data

This example uses the `CREATE PIPELINE` SQL statement to load data and the value of the search string `'year'` of the filename with each record in a pipeline. The Amazon® Web Services℠ (AWS℠) S3 FILTER option contains the filter for the year in a file path. In turn, the `METADATA` function uses the filter `'year'` value to load all records from files with the year `2019` in the specified path. For details about this pipeline definition and setup, see **Data Pipeline Load of CSV Data from S3**. The example assumes the filename follows Hive-style naming standards.

SQL

```
CREATE PIPELINE orders_pipeline
SOURCE
    S3
        ENDPOINT 'https://s3.us-east-1.amazonaws.com'
        BUCKET 'ocient-docs'
        FILTER '/year=2019/**'
EXTRACT
    FORMAT csv
    NUM_HEADER_LINES 1
INTO public.orders
SELECT
    $1 as id,
    $2 as user_id,
    $3 as product_id,
    $4 as subtotal,
    $5 as tax,
    $6 as total,
    $7 as discount,
    $8 as created_at,
    $9 as quantity,
    METADATA('hive_partition','year') AS hive;
```

# Deduplication in Data Pipelines

Ocient data pipelines deduplicate records by tracking load position and lifecycle, ensuring exactly-once delivery even when pipelines stop, resume, or update.

## Exactly Once Loading in Pipelines

The job of a pipeline is to load the data assigned to it exactly once. A pipeline maintains its own position during a load and enforces deduplication logic. The lifecycle of a pipeline object in the database defines both the deduplication logic and load position.

> Because the pipeline, not the target tables, defines the load position and deduplication scope, if the system truncates target tables or if the system drops and recreates a target table, the pipeline continues from its last position. It does not reset to the beginning position of the load if you attempt to load data into a new table.

Key benefits are:

- Pipeline Events — During the life of a pipeline, you can stop and resume the pipeline without duplicating source data or changing the position in a load.
- Pipeline Updates — You can modify pipelines using the `ALTER PIPELINE` SQL statement to update the transforms in a pipeline but maintain the current position in the load and the deduplication scope of the pipeline. For details, see **Update a Pipeline**.
- Exactly Once Loading — In the event of transient system failures, the pipeline ensures exactly-once loading into the target table through replay and deduplication guarantees.

Two concepts are critical to understand how Ocient® controls which data is loaded in a pipeline and how Ocient pipelines ensure exactly-once loading.

1. Load Position
2. Deduplication Scope

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Load Position

You can control the pipeline by starting, stopping, modifying, and resuming the pipeline. While running, each pipeline maintains its position in the overall load. When it has reached the end of all data, the pipeline completes and does not attempt to reload the data. To load the data again, you must create a new pipeline or drop and recreate the pipeline.

- For an Apache® Kafka®-based load, the position consists of using consumer group offsets appropriately to create checkpoints.
- For File-based loads, file details are stored in the `sys.pipeline_files` system catalog table and the system updates the status of each file as the load progresses.

In both cases, the load position defines where the pipeline resumes loading if stopped and resumed.

## Deduplication Scope

The deduplication scope defines the conditions under which a pipeline does not cause the same row to appear twice in a target table. This deduplication is how a pipeline ensures that it is safe to replay data during loading. This situation is common in failover situations or when you stop and restart a pipeline.

The deduplication scope is the unique combination of:

1. A pipeline object
2. A target table

A pipeline guarantees that if it sends the same row to the same target table twice, the system only loads it into the table once. If you drop and recreate either the pipeline or the table, then the situation is a new deduplication scope.

> ⚠ If you begin sending data to a new target table, this situation is a new deduplication scope. A row for the same record can appear in both the old and new tables.

## Restarts and Deduplication

You can restart a pipeline without creating duplicate data in the target tables. However, there are some limitations and key assumptions for each data source.

For example, in a file load, if you modify the contents of a file after the pipeline has started, then you can experience duplication of data or missed rows.

For more details and key considerations, see **Restarting a File Load** and **Restarting a Kafka Load**.

## Deduplication and DROP TABLE

You can drop a table using the `DROP TABLE` SQL statement and then recreate it with the same name. In this case, an existing pipeline loads into the new table. When you drop a table and recreate it, these actions do not update the load position of the pipeline. When you restart the pipeline, it resumes from the load position of the pipeline, and all records from that position forward are loaded with a new deduplication scope.

## Deduplication and TRUNCATE TABLE

You can truncate a table (using the `TRUNCATE TABLE` SQL statement) that is the target of a pipeline whether the pipeline is running or stopped. These actions do not update the load position of the pipeline or change the deduplication scope. The system deduplicates any data that was loaded before the truncate and replays after the truncate for any reason (e.g., restart or transient failure). Also, the system loads all new data.

> When you truncate the target tables and restart the pipeline, the Ocient System does not reload the data.

## Load Duplicate Data

Sometimes, you might want to load the same data multiple times, but the pipeline load position and deduplication scope prevent this.

If you want to load a second copy of the source data, you can follow one of these approaches:

File-Based Pipelines

- Drop and recreate the pipeline to reset the `sys.pipeline_files` system catalog table.
- Create a second pipeline with a new name and the same configuration.

Kafka Streaming Pipelines

- Drop the pipeline and recreate it with the same name, which defaults to the same consumer `group.id` but has a new deduplication scope. Then, reset the consumer group offsets using Kafka tools to the chosen starting point.
- Create a new pipeline with a different name and load from the beginning of the topic using `auto.offset.reset`.

# Error Tolerance in Data Pipelines

Configure the ERROR LIMIT clause on Ocient data pipelines to set how many record-level errors a batch tolerates before the pipeline enters a FAILED status.

## Error Limits

The error limit for SQL statements such as `START PIPELINE my_pipeline ERROR LIMIT 100` defines the number of record-level errors that a batch of files tolerates before failing the entire pipeline.

The error process is:

- Periodically, the Ocient® System assigns a batch of pending files to a Loader Node.
- The system enforces the maximum error limit for each batch.
- Files that have at least one record-level error reach the terminal status `LOADED_WITH_ERRORS` after all processing is complete.
- If the file batch reaches the error limit, the current file reaches the status `FAILED`, and then the pipeline status becomes `FAILED`. Processing stops on the pipeline.

By default, `BATCH` pipelines run with `ERROR LIMIT 0`. This permits zero errors on a pipeline. This setting stops the pipeline on the first error and stores the error in `sys.pipeline_errors.` When you restart the pipeline, it retries the failed file and failed record. The system does not duplicate any previously loaded data. To complete the load, fix the issue with the data or the pipeline definition or increase the error limit when you restart the pipeline.

## Unrecoverable File Errors

You can manage unrecoverable file errors such as Gzip decompression errors, tokenization errors, or missing files by starting the pipeline with the `FILE_ERROR` option.

The strictest setting is `FILE_ERROR FAIL`. When you use the `FAIL` setting, any file-level error causes the pipeline to fail. If any file is missing or cannot be processed, the

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

pipeline marks the file `FAILED`, sets the pipeline status to `FAILED`, and processing stops on the pipeline.

The most tolerant setting is `FILE_ERROR TOLERATE`. Use this setting in a statement such as `START PIPELINE my_pipeline ERROR FILE_ERROR TOLERATE`. When you use the `TOLERATE` setting, missing files reach the terminal status `SKIPPED`. Files that encounter other file-level errors reach the terminal status `LOADED_WITH_ERRORS`. When the Ocient System encounters a file-level error, processing stops on the file and continues with the next file in the partition. When you use the `TOLERATE` setting, the pipeline automatically executes with an unlimited error limit.

## Recoverability

If a pipeline fails when it tolerates no errors, manually fix the row or file where the error occurs and restart the pipeline so that the load proceeds with all records correctly deduplicated. Restarting the pipeline without fixing the error but with tolerance of record or file-level errors also allows the load to proceed with all records correctly deduplicated. However, restarts do not guarantee correct deduplication if you apply manual fixes after this point.

When a pipeline fails, the number of loaded rows is nondeterministic. As a result, the Ocient System does not guarantee the reflection of any manual modification of files with the statuses `SKIPPED`, `LOADED_WITH_ERRORS`, or `FAILED` in a restart operation. However, if the pipeline fails due to a low error limit, you can raise the error limit on a restart operation to allow the pipeline to make further progress.

You can use the `BAD_DATA_TARGET` option to capture failing records for troubleshooting and reloading.

## Restarts and Deduplication

Ocient pipelines enable the restart of a pipeline without creating duplicate data in the target tables. However, there are some limitations for each type of data source. For details, see **Data Pipelines**.

# Monitor Data Pipelines

Data Pipeline functionality allows for monitoring through system catalog tables, information schema views, and operational metrics endpoints.

You can monitor data pipelines through a combination of:

1. System catalog tables
2. Information schema views
3. Operational metrics endpoints for use with operations monitoring tools

> The Management UI **Ingestion** page provides a visual overview of all pipelines with their status, throughput, progress, and error counts. You can also start and stop pipelines directly from the UI.

This tutorial describes how to use these system catalog objects to monitor your pipelines:

- `information_schema.pipelines`
- `information_schema.pipeline_status`
- `sys.pipelines`
- `sys.pipeline_events`
- `sys.pipeline_errors`
- `sys.pipeline_files`
- `sys.pipeline_partitions`
- `sys.pipeline_metrics`
- `sys.pipeline_metrics_info`

A complete reference of system catalog tables and views is available in the **System Catalog**.

## Pipelines Information Schema

After you create a pipeline, two convenient views are most useful for observing the pipeline. At a glance, you can view the configuration of your pipeline in

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`information_schema.pipelines` and the status information in `information_schema.pipeline_status`.

Access these views conveniently with the `SHOW` command.

SQL

```
> SHOW PIPELINES;
+-----------------+-----------------+---------------+--------------+-------------
| database_name   | pipeline_name   | loading_mode  | source_type  | data_format
|-----------------+-----------------+---------------+--------------+-------------
| test            | my_pipeline     | BATCH         | FILESYSTEM   | CSV
+-----------------+-----------------+---------------+--------------+-------------
Fetched 1 rows
```

SQL

```
> SHOW PIPELINE_STATUS;
+-----------------+---------------+---------------------------+-----------+------
| database_name   | pipeline_name | table_names               | status    | statu
|-----------------+---------------+---------------------------+-----------+------
| test_database   | test_pipeline | ['test_schema.test_table'] | COMPLETED | Compl
+-----------------+---------------+---------------------------+-----------+------
Fetched 1 rows
```

For a quick look at the progress of a pipeline, the `SHOW PIPELINE_STATUS` command provides:

- Name
- Target tables
- Current status
- Last status message that was received in processing
- Percentage completion (from 0.0 - 1.0)
- Duration of pipeline execution
- Number of files and records processed
- Error counts

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

To join these two views to other catalog tables, use the `pipeline_name` to join to the `sys.pipelines` table and then join tables using the `pipeline_id`.

## Pipeline Catalog Tables

Beyond the information schema views, many catalog tables offer details about your pipelines.

| Table | Description | Importance |
|---|---|---|
| `sys.pipelines` | List of pipelines that exist and the configuration information. | High |
| `sys.pipeline_events` | Event log generated through the lifecycle of a pipeline. | High |
| `sys.pipeline_errors` | Log of errors created by pipelines during execution for troubleshooting record-level errors or system errors. | High |
| `sys.pipeline_files` | List of files that each file-based pipeline is loading or has loaded. | High |
| `sys.pipeline_partitions` | List of Apache® Kafka® source partitions on each Kafka streaming pipeline with relevant metadata for offsets. | Medium |
| `sys.pipeline_metrics` | Metrics that are regularly collected for each pipeline to capture performance and progress. | Medium |
| `sys.pipeline_metrics_info` | Descriptive details about the available pipeline metrics. Provides information about how to interpret each metric type. | Low |

### Monitor Activity and Events

While your pipeline is running, the pipeline generates events in the `sys.pipeline_events` system catalog table to mark significant checkpoints when something has occurred. You can use this table to observe progress and look for detailed messages about changes in the pipeline.

For example, the `sys.pipeline_events` table captures events when a pipeline is created, started, stopped, fails, and completed. This table also captures relevant system events such as rebalancing Kafka partitions or retrying a process due to a transient failure.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Pipeline events include messages from many different tasks. These tasks are the background processes that execute across different Loader Nodes during pipeline operation.

## Monitor Files or Partitions

For file-based loads, the `sys.pipeline_files` system catalog table contains one row for each file, which contains the status of the file and other file metadata such as filename, creation or modified timestamps, and the file size. The pipeline updates this list of files when it is started and maintains status information as it processes files. You can use this list to understand which files are loading, which succeeded, and which failed.

For Kafka partition-based loads, the `sys.pipeline_partitions` system catalog table contains one row for each partition, which contains the current offsets and record counts. You can use this information to understand how partitions are distributed across Loader Nodes and also to observe lag on each topic and partition.

## Monitor Performance

Pipeline performance metrics are captured in the `sys.pipeline_metrics` system catalog table. This table contains samples of the metrics over time. The Ocient® System collects samples regularly. You can query the samples using standard SQL queries to inspect the behavior of a single pipeline, a single task on a Loader Node, or across all pipelines. The `sys.pipeline_metrics_info` system catalog table provides metadata that explains the individual metric types.

See **Discover Insights from Data Pipeline System Catalog Tables** for a detailed description of how to use `sys.pipeline_metrics` and `sys.pipeline_metric_info` to monitor the performance of your pipelines. For the system catalog table definitions, see **System Catalog**.

## Monitor a Foreground Pipeline from Another Session

When you create a transactional pipeline with the `START FOREGROUND` clause, the SQL session that executes the statement blocks until the pipeline reaches an inactive state. Because the session is blocked, you must monitor the pipeline from a separate SQL session.

From a separate session, execute the `SHOW PIPELINE_STATUS` command to view the current status, last status message, percentage completion, duration, and file and record counts for the pipeline.

```
SQL

SHOW PIPELINE_STATUS;
```

You can also query the `sys.pipeline_metrics` system catalog table to observe the performance and progress metrics that the Ocient System collects regularly while the pipeline runs. For details about how to interpret each metric type, query the `sys.pipeline_metrics_info` system catalog table.

For more information about foreground pipelines, see **Transactional Data Pipelines**.

# Metrics Endpoints

In the same way that the Ocient System monitors system performance using **Statistics Monitoring** endpoints with operational monitoring tools, data pipelines expose an API that allows operators to capture performance metrics over time.

## Access Metrics Endpoints

You query the metrics using an HTTP endpoint on each Loader Node located at `<loader_ip_address_or_hostname>:8090/metrics/v1`.

For example, you can retrieve metrics from a Loader Node by executing this command from a shell on the node or by running a similar request from a monitoring agent on the node.

```
Text

curl http://localhost:8090/metrics/v1
```

Each metric is represented as a JSON object that contains:

- Metric name
- Metric value

- Scope information
- Query time
- Value units
- Whether or not the metric is incremental

Metrics can be incremental or instantaneous. Incremental metrics accumulate value over time, so they never decrease in value. Instantaneous metrics capture the current value, so they can decrease.

## Metrics Scope

Similar to the `sys.pipeline_metrics` system catalog table, the Ocient System scopes metrics to a Loader Node, a pipeline task, or a partition. You can determine the scope of a metric based on the presence of the `pipeline_name`, `pipeline_name_external`, and `partition` keys or reference the details in **Pipeline Metrics Details**.

| Scope | Description |
|---|---|
| Loader | Metrics scoped to a loader do not have information about pipelines or partitions. Because metrics are collected on each node, this scope contains all activity on the node where you access the endpoint. |
| Pipeline | Metrics scoped to a pipeline have a key named `pipeline_name` with a value that corresponds to the identifier of the extractor task with hyphens removed. The metrics also have a key named `pipeline_name_external` with a value that corresponds to the identifier of the pipeline. |
| Partition | Metrics scoped to a partition have the same keys as metrics scoped to a pipeline. The metrics also have a key named `partition` with a value that is the stream source identifier of the partition. |

### Examples

This JSON structure contains a metric scoped to a Loader Node.

JSON

```
{
  "name": "usage.os.heap",
  "time": 1713993689613976,
  "timestamp": "2024-04-24T21:21:29.613976119Z",
  "value": 317855288,
  "units": "bytes",
  "incremental": false
}
```

This JSON structure contains a metric scoped to a pipeline.

JSON

```
{
  "name": "count.record.sent",
  "time": 1713994532578624,
  "timestamp": "2024-04-24T21:35:32.578624253Z",
  "value": 100000,
  "units": "unitless",
  "incremental": true,
  "pipeline_name_external": "test-rest-external-create",
  "pipeline_name": "test"
}
```

This JSON structure contains a metric scoped to a partition.

© 2026 Ocient, Inc

JSON

```
{
  "name": "duration.record.processed",
  "time": 1714509826724477,
  "timestamp": "2024-04-30T20:43:46.724477142Z",
  "value": 322432,
  "units": "milliseconds",
  "incremental": true,
  "pipeline_name_external": "test-rest-external-create",
  "pipeline_name": "58ff07cf732846f9830b728b3a8e4a7a",
  "partition": "226979",
  "sink_index": "0"
}
```

## Pipeline Metrics Details

| Name | Scope | Description | Importance |
|---|---|---|---|
| `count.error` | pipeline | The number of errors that the extractor task logs during pipeline execution. This count includes the errors that the `count.record.error` and `count.sink.error` metrics count, but does not include resource exhaustion events. | High |
| `count.file.fail` | pipeline | The number of files that have file-level errors in the extractor task, such as a file that is missing when the extractor task tries to load it, a decompression failure, or invalid source data. | High |
| `count.file.listed` | pipeline | The total number of files listed in the static file list. | High |
| `count.file.processed` | pipeline | The number of files that have been extracted from the source for processing. The Ocient System tracks this number before tokenization, transformation, or sending to the sink. This number does not indicate the durability of the files or if files load with errors. | Medium |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Name | Scope | Description | Importance |
| --- | --- | --- | --- |
| `count.file.total` | pipeline | The total number of files for each task. | High |
| `count.native.bytes.used` | pipeline | The amount of memory, in bytes, currently allocated for reading Apache® Apache® Parquet™ source data. | Low |
| `count.partition.durable.offset.committed` | partition | The last committed offset of the Kafka partition for the consumer group. | High |
| `count.partition.offset.lag` | partition | `count.partition.offset.max - count.partition.durable.offset.committed` for a specified Kafka partition. | Medium |
| `count.partition.offset.max` | partition | The maximum offset of the Kafka partition. | High |
| `count.partition.records.failed` | partition | The count of failures when processing records during pipeline execution for a specified Kafka partition. | High |
| `count.partition.records.processed` | partition | The number of records that have been extracted for processing on a specified Kafka partition. | Medium |
| `count.partitions` | partition | The number of partitions in this extractor task. | High |
| `count.record.bytes.maximum` | partition | The largest record processed in bytes. | Medium |
| `count.record.bytes.minimum` | partition | The smallest record processed in bytes. | Medium |
| `count.record.durable` | partition | The number of records that the pipeline has sent to the Loader Node and that are durable. | High |
| `count.record.error` | pipeline | The number of record-level errors that the extractor task logs. These errors are extraction or transformation errors that the pipeline can tolerate by skipping the record when you specify the `ERROR LIMIT` option in the `START PIPELINE` SQL statement. | High |
| `count.record.sent` | pipeline | The number of records that the pipeline has fully transformed and | High |

| Name | Scope | Description | Importance |
|---|---|---|---|
| | | sent to the Loader Node to be made durable. | |
| `count.signal.kill` | pipeline | The number of times that a partition has been killed due to resource exhaustion. | Low |
| `count.sink.bytes.flushed` | partition | The number of bytes that the pipeline sends to the Loader Node to be made durable. | Medium |
| `count.sink.error` | pipeline | The number of sink-specific errors that the extractor task logs for each target table. | Medium |
| `count.source.bytes.decompressed` | partition | The number of bytes of decompressed data that the pipeline retrieves from the source. This metric is not present for loads of uncompressed data. | Medium |
| `count.source.bytes.ingested` | partition | The number of bytes of raw data that the pipeline retrieves from the source. | High |
| `count.stream.paused` | partition | The number of times the processing of the record stream has been paused due to reaching a high watermark. | Medium |
| `count.stream.unpaused` | partition | The number of times the processing of the record stream has been unpaused due to reaching a low watermark. | Medium |
| `duration.file.listed` | pipeline | The number of milliseconds spent listing files from the data source. | High |
| `duration.record.durable` | partition | The duration in milliseconds for making records durable.<br>**ℹ** The database takes time to make records durable, so this duration might be longer than the record processing duration. | Medium |
| `duration.record.processed` | partition | The duration in milliseconds for reading the records from the source, transforming them, and buffering them for sending to the sink. | Medium |
| `uptime` | Loader Node | The number of seconds after the last restart of the extraction | High |

| Name | Scope | Description | Importance |
| --- | --- | --- | --- |
| | | process. | |
| `usage.os.heap` | Loader Node | The number of bytes used in the heap. | High |
| `usage.os.percentage.cpu` | Loader Node | The percentage of CPU used by the JVM®. | High |

# Manage Errors in Data Pipelines

Guide to managing errors in Ocient data pipelines using JSON from Kafka, including bad-data handling, record inspection, pipeline status, and error limits.

When you load data into Ocient®, you can manage the way that the system responds to errors. This guide outlines different mechanisms for managing errors through examples.

The guide uses the same setup as **Data Pipeline Load of JSON Data from Kafka** but it modifies that pipeline to illustrate how to manage errors that you might encounter in data pipeline functionality.

You learn about:

- Bad data and error handling
  - Inspecting record-level processing errors
  - Configuring a bad data target
- Controlling pipeline behavior when you encounter errors
  - File-level error behavior
  - Record-level error behavior
- Understanding pipeline statuses in file loading

## Step 1: Complete the Load JSON Data from Kafka Tutorial

See **Data Pipeline Load of JSON Data from Kafka** and complete the tutorial, then return to this guide for Step 2.

## Step 2: Modify the Pipeline with a Bad Data Target

Bad data targets are the way to capture record-level errors for later troubleshooting and correction. Data pipelines support an Apache® Kafka® bad data target that allows

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

you to send any failing records to a designated Kafka topic. This topic supports easy replay of those records in a separate recovery pipeline or inspection of the failing records.

For details about bad data targets, see the **Bad Data Targets Reference**.

## Stop the Data Pipeline

Stop the `orders_pipeline` data pipeline using the `STOP PIPELINE` SQL statement.

SQL

```
STOP PIPELINE orders_pipeline;
```

Inspect the pipeline status using this `SELECT` SQL statement and the `pipeline_status` information schema view.

SQL

```
SELECT
  status
FROM information_schema.pipeline_status
WHERE
  pipeline_name = 'orders_pipeline';
```

While the pipeline is stopping, the status might appear as `STOPPING` while the pipeline wraps up work in process and commits offsets back to Kafka. After the status changes to `STOPPED`, you can proceed to the next step. A pipeline might not be in a running state when you modify it.

## Modify the Data Pipeline

In this example, use the `CREATE OR REPLACE PIPELINE` SQL statement to update the data pipeline. Because the consumer group identifier does not change, the pipeline resumes from the same offsets in the Kafka topic. This statement creates a new pipeline identifier. To update the pipeline in place and retain its identifier, use the `ALTER PIPELINE` SQL statement instead. For details, see **Update a Pipeline**.

Add the `BAD_DATA_TARGET` option and specify the Kafka target and details. Use the same Kafka broker as the source and bad data target in this example.

SQL

```
CREATE OR REPLACE PIPELINE orders_pipeline
BAD_DATA_TARGET
  KAFKA
    BOOTSTRAP_SERVERS '192.0.2.1:9092'
    TOPIC 'orders_errors'
SOURCE
  KAFKA
    BOOTSTRAP_SERVERS '192.0.2.1:9092'
    TOPIC 'orders'
EXTRACT
  FORMAT json
INTO public.orders
SELECT
  $id as id,
  $user_id as user_id,
  $product_id as product_id,
  $subtotal as subtotal,
  $tax as tax,
  $total as total,
  $discount as discount,
  $created_at as created_at,
  $quantity as quantity;
```

## Step 3: Start the Data Pipeline with an Error Limit

Start the `orders_pipeline` data pipeline. In this case, set a maximum error limit so that the pipeline fails if 10 errors occur. An `ERROR LIMIT` might not be chosen for a continuously streaming pipeline if it is critical to keep up with newly arriving data, because the pipeline can stop suddenly and cause data freshness to fall behind. However, this example shows how error limits behave and how error states appear in pipelines.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
START PIPELINE orders_pipeline
ERROR LIMIT 10;
```

The pipeline status changes to `STARTED` to indicate that it has begun processing.

> For file-based loads, the `START PIPELINE` SQL statement includes options for `FILE_ERRORS` that are useful for controlling error handling in different file failure modes. Options include failing on error, skipping on file error, and tolerating file-level errors. See the **Start Pipeline Command Reference** for details.

## Step 4: Produce Data with Errors into Kafka

With the data pipeline in place and running, data immediately begins to load from the Kafka topics that are configured in the pipeline from the last committed offsets after the pipeline stopped.

For test purposes, **kafkacat** is a helpful utility that makes it easy to produce records in a topic. For example, if you have a file of sample data `orders_with_errors.jsonl` in a JSONL format (newline-delimited JSON records), you can run this command to send those records into your Kafka broker. `<broker_ip_address>` is the IP address of the Kafka broker and `<topic_name>` is the name of the Kafka topic.

Shell

```
kafkacat -b <broker_ip_address>:9092 -t <topic_name> -T -P -l orders_with_errors.
```

Save an example document to your file system to use for this test. For this example, you can download an example file from **https://ocient-docs.s3.amazonaws.com/metabase_samples/jsonl/orders_with_errors.jsonl** and save it to `~/orders_with_errors.jsonl`.

Assume the broker is running at `192.0.2.1`, to send data into the `orders` topic defined in the pipeline definition, run this command.

Shell

```
kafkacat -b 192.0.2.1:9092 -t orders -T -P -l orders_with_errors.jsonl
```

This command pushes the entire JSONL file of messages into Kafka with one record per line. As these records are produced into Kafka, the running pipeline begins to load them into Ocient.

## Step 5: Observe Loading Progress

With your pipeline running, data immediately begins to load from the Kafka topic. The pipeline creates parallel Kafka Consumers for each partition. If there are more partitions than processing cores available, the pipeline automatically handles spreading consumers across available processing cores and Loader Nodes.

You can check the pipeline status and progress by querying the `information_schema.pipeline_status` view or running the command `SHOW PIPELINE_STATUS`. Use the view to query the name of the pipeline, status, number of failed records, and the status message.

SQL

```
SELECT
  pipeline_name, status, records_failed, status_message
FROM
  information_schema.pipeline_status;
```

*Output*

SQL

```
pipeline_name       status     records_failed    status_message
-------------------------------------------------------------------------------
orders_pipeline     FAILED     11                Started processing pipeline orde
```

### Inspect Errors

Examine the pipeline errors directly using the `sys.pipeline_errors` system catalog table.

```SQL
SELECT count(*) FROM sys.pipeline_errors;
```

*Output*

```SQL
count(*)
--------------------
11
```

Using this table, you can see detailed error messages, the source of the error, the column that encountered the error, and other helpful details to help troubleshoot why the record did not load.

```SQL
SELECT * from sys.pipeline_errors;
```

*Output*

SQL

```
pipeline_id                          extractor_task_id                    error_i
-------------------------------------------------------------------------------
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 1
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 2
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 3
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 4
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 5
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 6
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 7
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 8
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 9
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 10
f3ca5a1c-1bf4-40a4-8d01-b8c028fdfb58 1ecc5c4a-613f-48a5-8234-2257317a4a85 11
```

For a more abbreviated view, query a few columns in the table. This example queries the error type, error code, error message, and name of the column.

SQL

```sql
SELECT
  error_type, error_code, error_message, column_name
FROM sys.pipeline_errors;
```

*Output*

SQL

```
error_type          error_code      error_message
-------------------------------------------------------------------------------
TRANSFORMATION      OLT01           Failed to transform value 'not_int' using Asc
TRANSFORMATION      OLT01           Failed to transform value '2019-08-22T:30:42.
TRANSFORMATION      OLT01           Failed to transform value 'not_decimal' using
TRANSFORMATION      OLT01           Failed to transform value '55.11' using Ascii
TRANSFORMATION      OLT01           Failed to transform value 'not_int' using Asc
TRANSFORMATION      OLS00           Failed to load transformed value 'null' to si
TRANSFORMATION      OLS00           Failed to load transformed value 'null' to si
TRANSFORMATION      OLS00           Failed to load transformed value 'null' to si
TRANSFORMATION      OLS00           Failed to load transformed value 'null' to si
TRANSFORMATION      OLT03           Failed to transform value '2018-06-26' using
TRANSFORMATION      OLS00           Failed to load transformed value 'null' to si
```

From this result set, you can quickly inspect error messages, such as the first error message.

Text

```
Failed to transform value 'not_int' using AsciiIntTransform. Details: Invalid ASC
```

This message occurs for the `user_id` column. From this information, you can see that you have some bad data in the data set.

In other errors, you can see the error code `OLS00` and a message that indicates some issues with `NULL` handling. The table has a `NOT NULL` setting on a few columns, but the data is missing on the source records. Fix this by updating the pipeline to supply a default, or you can modify the table schema if you expect NULLs to occur and you do not have a reasonable default. For a continuous pipeline, you might expect to see an error like this if something changes in the data source.

## Inspect Bad Data

To observe the original data, you can go to the original source file from this example, or you can load the specific message from the bad data topic that was configured to inspect it.

Using the kafkacat utility, you can consume the messages on the topic. This command consumes one message on the `orders_errors` topic.

Shell

```
kafkacat -C -b 192.0.2.1:9092 -t orders_errors -o -1 -c 1
```

*Output*

Shell

```
{"id": 1011, "user_id": 3, "subtotal": 76.83, "tax": 5.28, "total": 82.11, "disc
```

A quick inspection of the source data reveals that this record is missing the `product_id` field, but this is a required column in our table.

If you run this command again, but with the `-J` flag, you can inspect the headers that are associated with the pipeline. The headers in the bad data target capture important metadata from the data pipeline execution that you can use to troubleshoot the failing data, including the `error_message`.

Shell

```
kafkacat -C -b 192.0.2.1:9092 -t orders_errors -o -1 -c 1 -J
```

*Output*

SQL

```
{"topic":"orders_errors","partition":0,"offset":89,"tstype":"create","ts":1713566
```

## Next Steps

Now that you have loaded data into tables, you can explore a few advanced topics, including handling pipeline errors, loading from other data sources, loading different data formats, and transforming data.

# Frequently Asked Questions for Data Pipelines

Frequently asked questions about Ocient data pipelines, covering setup, deduplication, error handling, monitoring, performance, and source-format support.

The questions featured in this topic cover information that you need most often when you start creating and running data pipelines.

## Running Pipelines

### Who can run a data pipeline?

Any database user with `EXECUTE` pipeline privileges can run a data pipeline on their database. This privilege allows database administrators to distinguish the users who can create pipelines from those who can start them.

To learn more about access control for pipelines, see **DCL Pipeline Privileges**.

### Do pipelines run automatically after creation?

No, pipelines have a user-controlled lifecycle that starts with creation. After you create a data pipeline, you determine when to start the pipeline. A pipeline either completes successfully or moves to a failed status if the Ocient® System reaches an error limit.

For a basic batch file load, you would first use the `CREATE PIPELINE` SQL statement and then the `START PIPELINE` statement. After all data is successfully loaded, the pipeline status changes to completed.

### How do you run multiple pipelines at the same time?

Multiple data pipelines can run concurrently in Ocient. To run more than one simultaneously, any user with privileges to start a pipeline can use the `START PIPELINE` SQL statement. Execution of this statement begins the execution of the

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

selected pipeline. The Ocient System uses Loader Nodes in parallel to process all of the pipelines that are running.

If you need to control the relative priority of one pipeline over another when running concurrently, use advanced pipeline settings to limit the number of cores allocated to a specified pipeline or isolate the pipeline to a particular set of Loader Nodes.

### What happens if I start a pipeline that has been stopped?

When you execute a `START PIPELINE` SQL statement on a pipeline that has been stopped due to either hitting an `ERROR LIMIT` or due to user intervention, the load resumes from the last point in the pipeline. Hence, you can effectively pause a pipeline and resume from the last checkpoint in the pipeline. This feature works for continuous pipelines such as Apache® Kafka® pipelines as well as batch pipelines.

You can stop a pipeline in two ways. The `STOP PIPELINE` SQL statement stops the pipeline as soon as possible and can leave files in intermediate statuses. The `QUIESCE PIPELINE` statement stops the pipeline gracefully and leaves a clean breakpoint with no partially loaded files. In both cases, the pipeline resumes from its last checkpoint, and the Ocient System deduplicates any records that the pipeline already loaded. For details, see **QUIESCE PIPELINE**.

Common uses of stopping and resuming a pipeline are:

- Stopping to update the transformations in a continuous pipeline.
- Stopping to update the table schema and refresh a pipeline.
- Stopping to allow a higher priority workload to proceed.
- Stopping for maintenance.

⚠ It is important to exercise caution when resuming a pipeline to ensure that the files in the underlying data source have not changed. Modifying data in the source for an in-process pipeline can result in unexpected results, such as duplicate data.

## File Loading

### When is the file list determined for a batch file load?

When you load a batch of files in a data pipeline, the Ocient System determines the batch when the pipeline starts using the bucket, the prefix, and the filter parameters you specify in your pipeline. This batch of files is frozen until the pipeline completes. Even if the batch pipeline stops and restarts, the Ocient System keeps the list of files constant.

### Can I update the file list after starting a pipeline?

You cannot manually modify the file list for a batch pipeline. When a pipeline restarts, it finishes the files that were determined when the batch was first established.

To add files that arrive on the file system after a batch pipeline was first started, you can create a new batch pipeline that uses filters to load all files created after a specified timestamp.

### What is the behavior if I start a pipeline that has been stopped?

When you start a file-based pipeline that has been stopped, the pipeline adds any new files to the pipeline as files with the `PENDING` status. The pipeline then loads these files as execution proceeds. The Ocient System does not reload any files that the pipeline has already loaded.

> ⚠ It is important to exercise caution when resuming a pipeline to ensure that the files in the underlying data source have not changed. When you modify data in the source for an in-process pipeline, the Ocient System can have unexpected results, such as duplicate data.

### What options exist to maximize performance on S3-type file loads?

The most common performance enhancement for Amazon® Web Services℠ (AWS℠) S3 file loads is the `PREFIX` parameter in your pipeline. This setting restricts the files in the bucket that your pipeline considers, speeding up listing operations.

You can also use other advanced options such as `MAX_CONCURRENCY`, `REQUEST_DEPTH`, and `REQUEST_RETRIES` described in **S3 Source Options**.

## Kafka Loading

## How does a continuous Kafka streaming pipeline work?

Continuous pipelines for Kafka stream records from Kafka partitions and ensure exactly-once semantics are delivered. Ocient assigns consumers to different Loader Nodes and commits offsets back on the assigned partitions as the source data loads into Ocient. This operation critically only occurs after data is durable in Ocient, which means that the system replicates data in such a way that the loss of a configurable number of nodes would not lead to data loss.

All supported data formats are compatible with Kafka streaming pipelines.

When you run a continuous Kafka streaming pipeline, the pipeline is never complete so it remains in a running state. You can observe progress using the standard system catalog tables and the Kafka-specific table `sys.pipeline_partitions` that captures individual partition assignments and lag.

When you stop and restart a Kafka streaming pipeline, it resumes from the last commit checkpoint and continues processing records. The Ocient System deduplicates any record that has already been sent to Ocient but not committed to Kafka in the Loader Nodes.

## How do I update the transforms or the table schema in a continuous Kafka streaming pipeline?

To update transforms in a Kafka streaming pipeline, first, quiesce the pipeline by executing the `QUIESCE PIPELINE` SQL statement. After the pipeline reaches the `QUIESCED` status, the pipeline has committed all consumer offsets to Kafka, and you can execute an `ALTER PIPELINE` SQL statement. This statement allows you to update the transformations in the pipeline. Because the consumer group identifier does not change, the pipeline resumes from the last Kafka committed offsets when you execute the `START PIPELINE` SQL statement. The `ALTER PIPELINE` statement retains the identifier of the pipeline. For details, see **QUIESCE PIPELINE**, **ALTER PIPELINE**, and **Update a Pipeline**.

## Where does a Kafka streaming pipeline resume loading after a stop and then start of the pipeline?

When you execute the `START PIPELINE` SQL statement, the pipeline resumes from the last Kafka committed offsets. The Loader Nodes deduplicate any record that has already been sent to the Loader Nodes but is not yet committed to Kafka.

If you have never started a Kafka streaming pipeline, the pipeline starts from the configured `auto.offset.reset` value. You can set this value in the `CONFIG` option of a Kafka streaming pipeline. The Ocient System uses this value when a pipeline first starts to establish the consumer group for the pipeline.

For more details about Kafka configuration, see **Kafka Source Options**.

# Data Duplication and Deduplication

## What records are deduplicated during loading?

Ocient Loader Nodes deduplicate data that is loaded on the same pipeline. You can think of the deduplication scope of a pipeline as being tied to the life of the pipeline database object.

If you drop a pipeline and create a new one with the same name, this data is not deduplicated.

For a specified pipeline, the Ocient System deduplicates data automatically when you stop and resume a pipeline. The system ensures that no duplicate data is loaded for any reprocessed data due to managing watermarks with data sources such as Kafka or S3.

It is important to note that deduplication in Ocient is based on a shared contract between the data source and the Ocient System. Deduplication is not based on a primary key or record identifier that is part of the data itself. The **What mistakes can accidentally lead to duplicating data?** question explains the implications more clearly.

## How can I load the same data set twice into the same table?

Sometimes, it is useful to load data multiple times for testing, but deduplication can get in the way.

To load the same data set twice in the same table, there are two simple approaches:

1. Drop the pipeline from the first load, create the same pipeline, and run it to completion.
2. Create a new pipeline with the same SQL statement as the original, but with a new name, and run it to completion.

In both cases, the Ocient System does not deduplicate the data, and you can load a second copy of your data.

### What mistakes can accidentally lead to duplicating data?

The Ocient System can have duplicate data when the deduplication contract between the source and the pipeline is not maintained.

Ocient uses a proprietary approach to deduplication that helps it deliver high throughput when loading while still ensuring exactly-once semantics. If the data in the source changes during the execution of a pipeline, the changes can lead to a mismatch in the way the Ocient System determines the deduplication identifier for a record.

Things to avoid include:

- Modifying a file in the source file system after it has been included in a pipeline, but the pipeline has not been completed.
- Deleting a file in the source that has been included in a pipeline, but the pipeline has not been completed.

You can add new files safely to a pipeline before it completes, but you should avoid modifying files already registered by the pipeline and appear in the `sys.pipeline_files` system catalog table.

## Troubleshooting and Errors

### How do I detect when an entire file fails in a pipeline?

If an entire file has failed, you can see this in the `sys.pipeline_files` system catalog table. Any file with the `FAILED` status indicates that the file failed to process. This failure can occur due to a file-level error, such as corruption.

In addition, if a file has the `SKIPPED` status, this status indicates that the file was skipped when processing the pipeline. You can control this behavior using the `FILE_ERROR` setting in the `START PIPELINE` SQL statement.

If a specified file experiences record-level errors, but the Ocient System processes the file, the file has the `LOADED_WITH_ERRORS` status.

### How do I find the individual records that failed to load?

You can find the individual errors in the `sys.pipeline_errors` system catalog table.

You can determine if a pipeline encounters errors by viewing the `information_schema.pipeline_status` view that includes counts of records with errors.

## Transformations

### How can I convert a string representation of an array of data into an array data type?

The Ocient System automatically converts a string representation of an array into an array using the settings defined on your pipeline. The system uses the `CLOSE_ARRAY`, `OPEN_ARRAY`, and `ARRAY_ELEMENT_DELIMITER` settings to convert a string to a target array column type. These types default to a PostgreSQL®-style array (e.g., `{1,2,3}`).

For details, see the supported options in **Extract Options**.

### How do I apply a transformation function to an array of data?

Data pipelines do not yet support the mapping of arbitrary transformation functions over an array. However, the Ocient System supports casting and type conversion. You can apply an array cast to an array and the system applies the type of each element as a conversion to the elements of the array.

For details, see **Scalar Transformation Functions and Casting**.

### My data is in a non UTF-8 encoding. How do I get the load to decode my character set properly?

You can change the character set of your pipeline using the `CHARSET_NAME` option in a pipeline. For details, see the supported options in **Extract Options**.

## Can a data pipeline extract nested data in JSON?

Ocient supports a JSON selector syntax similar to JSON Path. The Ocient System can extract individual keys as well as nested data. A simple example is `$order.user.first_name`, which extracts the first name `first_name` from the `user` object on the `order` object in JSON.

For details, see **Supported JSON Selectors**.

## Can a data pipeline extract attributes of objects in an array in JSON?

Ocient supports a JSON selector syntax similar to JSON Path. The Ocient System can extract individual keys, nested objects, arrays, and arrays of objects. The system can also project a selector into the arrays. A simple example is `$data.line_items[].price`, which extracts a one-dimensional array of prices `price` from the `line_items` array inside the `data` object.

For details, see **Supported JSON Selectors**.

## How do I apply a user-defined transformation to the data?

Data Pipelines support the creation of user-defined functions that you can use to apply more advanced transformations. For details, see the **CREATE PIPELINE FUNCTION** SQL statement.

## What automatic conversions does Ocient perform from my source data to the target columns?

The Ocient System supports many automatic conversions to make it easy to load source data into your target tables. `VARCHAR` data automatically casts into most target column types. The system casts many data types automatically to a `VARCHAR` target column. Some other common automatic conversions, such as `BIGINT` to `TIMESTAMP`, are supported, especially where the conversion is lossless.

For details, see **Data Types for Data Pipelines**.

## How do I cast data to an array column?

To cast to an array column, use a casting function. This function converts a string of data in the configured array format to the array type you specify, casting the elements to the inner type. For example, if `$my_column` represents the data `'{123,456,789}'` and your pipeline is using the default `CLOSE_ARRAY`, `OPEN_ARRAY`, and `ARRAY_ELEMENT_DELIMITER` settings, this expression snippet casts the elements to an array of `INT` values. Ocient also automatically casts `$my_column` in this example to an `INT[]` when that is the type of the target column.

SQL

```
CREATE PIPELINE
  ...
SELECT
  INT[]($my_column) as column_array_of_ints;
```

## How do I cast data to a tuple column?

Similar to casting to an array column, you can cast to a tuple column using tuple casting syntax. For example, if `$my_column` represents the data `'(123,test)'`, and your pipeline is using the default `CLOSE_TUPLE`, `OPEN_TUPLE`, and `TUPLE_ELEMENT_DELIMITER` settings, this expression snippet casts the elements as a tuple of an integer and a string `TUPLE<<int,varchar>>`.

SQL

```
CREATE PIPELINE
  ...
SELECT
  TUPLE<<int,varchar>>($my_column) as column_tuple;
```

# Query Ocient

Master querying techniques in Ocient's data warehouse, including tips for optimizing performance and handling complex data queries.

The OcientAIQ™ Unified Data Platform contains one or more SQL relational databases. Ocient® follows the PostgreSQL® dialect closely, and most functions operate the same in Ocient as in PostgreSQL. You can use the `SELECT` SQL statement to query data. For details, see the **Data Query Language (DQL) Statement Reference**.

- **Quick Start Querying**

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# Quick Start Querying

Quick start tutorial for querying data in Ocient, covering connection setup, basic SELECT statements, filtering, joining, and aggregating sample datasets.

This example demonstrates a quick start to begin querying an Ocient® System.

## Prerequisites

To get started querying in Ocient, the following are required:

1. A valid username and password for your Ocient System — These credentials can be obtained from your Database Administrator or System Administrator.
2. Network access to the SQL Nodes and the IP Address of the Hostname of these nodes in the Ocient System.
3. The port used for SQL Nodes. By default, this is `4050`.
4. A SQL Client or SQL Driver — This example uses the Ocient JDBC Driver. See **Connect Using JDBC**.

## Execute a Query

With these prerequisites, you can construct a connection string for your SQL Client of choice, connect, and begin querying Ocient in a few minutes. This example assumes the use of the JDBC driver and CLI. If using a different connection method, see **Connect to Ocient** to complete Step 2.

### Step 1: Create a Connection String

A connection string follows a standard format for Ocient.

SQL

```
jdbc:ocient://<HOSTNAME_OR_IP_ADDRESS>:<PORT>/<DATABASE>
```

In this example, you are going to replace each of the placeholders with the following:

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- PORT: `4050`
- HOSTNAME_OR_IP_ADDRESS: `10.10.1.1`
- DATABASE: `system`

Some systems use a hostname like `sql1.example.com` instead of an IP Address. Additionally, if you have a database configured already, use that instead of `system` to access your tables.

The final connection string is:

```SQL
jdbc:ocient://10.10.1.1:4050/system
```

## Step 2: Connect

Start the JDBC CLI according to the instructions in **Connect Using JDBC**. You need to specify a username and password.

The Fully Qualified Username is specified as `<username>@<database>`, so in your case, for a username of `example_user`, enter `example_user@system`.

Next, you should see an Ocient CLI prompt:

```Shell
Ocient> _
```

Enter the connect statement using your connection string:

```Shell
connect to jdbc:ocient://10.10.1.1:4050/system;
```

You receive a response similar to `Connected to jdbc:ocient://10.10.1.1:4050/system` indicating that you are now connected.

### Step 3: Execute a Query

You can now query any user tables or system catalog tables to which you have access in the database. System Catalog tables provide a wealth of information about the underlying system and configuration. Because you are connected to the system database, you can begin with a few catalog queries.

At the Ocient prompt, enter this SQL statement that displays information for all tables in the system.

SQL

```
Ocient> SELECT * FROM information_schema.tables;
```

To filter this information, use the LIKE predicate.

SQL

```
Ocient> SELECT * FROM information_schema.tables WHERE table_name LIKE '%data%';
```

Now that you are connected, you can execute any SQL queries or perform Database Administrator operations like **Data Definition Language (DDL) Statement Reference** or **Data Control Language (DCL) Statement Reference** where you have permission.

# Query Performance Tuning

The Query Performance Tuning page explains how to optimize query execution in Ocient to achieve low latency and high throughput on large, complex workloads.

This guide summarizes tuning techniques for Ocient® SQL querying. These techniques fall into these stages:

- **Pre-query tuning** — Tools to optimize query filters and lookups, including segment keys, indexing, and compression options. You must apply these tools before loading any data.
- **Query performance tuning** — Techniques to improve query performance at execution time.
- **Query performance analysis** — Tools and tips for monitoring queries and analyzing performance.

## Pre-Query Tuning

Carefully designing tables and storage with forethought can yield the largest query performance gains. Use these tools during table design:

- Apply TimeKeys — Use the TimeKey® to partition by time and enable efficient pruning for time-bounded filters and rollups. For details, see **TimeKeys**.
- Apply clustering keys and indexes:
  - Use the `CLUSTERING KEY` keywords to co-locate rows with commonly filtered or joined columns to reduce input and output (I/O). For details, see **Clustering Key**.
  - Use the `CLUSTERING INDEX` keywords to boost performance on any additional clustered column combinations. For details, see **Clustering Indexes**.
- Use secondary indexes — Create secondary indexes on columns that are frequently selected, especially for filtering predicates. These indexes can overlap with columns that already use segment keys or clustering indexes. For details, see **Secondary Indexes**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- Table compression and encoding:
  - Choose compression to lower storage and I/O while keeping CPU affordable for your workload. For details, see **Table Compression Options**.
  - Consider column cardinality and skew. Leverage dictionary compression for repeated values. For details, see **Global Dictionary Compression**.

For examples of these different tools and use cases, see **CREATE TABLE SQL Statement Examples**.

## Query Performance Tuning

Shape queries to minimize work at execution, align with indexes and data layout, and use runtime controls and caching to govern resources and reuse results. Use these methods while writing a query to tune performance:

- Adhere to query best practices:
  - Filter and aggregate early. Apply the most selective predicates as soon as possible in a query.
  - Avoid unnecessary use of the `DISTINCT` keyword. Also, avoid the use of many columns in a `SELECT` SQL statement.
  - Avoid applying functions on indexed columns in predicates (e.g., `WHERE LOWER(city) = 'chicago'`) because it can impact index and join performance. Instead, create a normalized companion column (e.g., `city_lower`), index it, and use it for queries.
  - Avoid sub-queries in the `SELECT` statement where possible. Use the `JOIN` keyword to join queries or use window functions when possible instead.
  - If you have a column with no duplicate values, use the `UNION ALL` keywords instead of the `UNION` keyword to avoid deduplication overhead.
- Apply workload management — Route heavy and long-running queries to batch classes and keep interactive queries in low-latency classes. For details, see **Workload Management Walkthrough**.
- Use result set caching — For recurring, identical queries, leverage caching to store query results and bypass execution. For details, see **Result Set Caching**.

# Query Performance Analysis

Measure, inspect, and iterate on query performance using analysis tools, system catalog tables and views, and statistics. Use these techniques to analyze the performance of a query:

- Query analysis ( `EXPLAIN` tooling):
  - Inspect the logical and execution plans of your query. Focus on the largest operators by time and rows. For details, see **Query Analysis**.
  - Compare the performance of alternative query structures and index choices.
- System catalog and information schema — Use system catalog tables and information schema views to understand table sizes, index usage, and the performance of queries during execution. For examples of capturing common query metrics, see **Discover Insights From System Catalog Tables**.
- Statistics monitoring and cache management — Monitor key performance metrics and statistics. For details, see **Set Up System Monitoring with the TIG Stack and Kapacitor**.

# Ocient HTTP Query API

The Ocient HTTP Query API lets you execute SQL statements over REST. The API follows the OpenAPI Specification (Swagger) for tooling and client generation.

The OcientAIQ™ Unified Data Platform provides an HTTP Query API that enables the execution of SQL statements. This page uses command-line examples using `curl`.

The HTTP Query API returns data in JSON format by default. The default header value is `Accept: application/json`.

## API Documentation

The API follows OpenAPI Specification (Swagger®) guidelines, which you can access in these formats from any SQL Node address `{sql_node_address}`:

- YAML format: `/openapi.yaml` endpoint
- JSON format: `/openapi.json` endpoint

### YAML Download Example

CURL

```
curl https://{sql_node_address}/openapi.yaml
```

### JSON Download Example

CURL

```
curl https://{sql_node_address}/openapi.json
```

You can use these specifications with various OpenAPI tools for code generation, testing, and documentation.

## Connection Setup

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

The connectivity pool defines connection settings for SQL Nodes, including their open port and address. For details, see **CONNECTIVITY POOL**.

A standard production install enables the OpenAPI port by default. At bootstrap, the system creates a default `system` connectivity pool and sets the `openapi_port` value of each participant to `443 + node port offset`. This setting mirrors the offset that the SQL port ( `4050` ) and REST port ( `9090` ) already apply. You do not need to configure anything to reach the HTTP Query API or web UI on a fresh cluster.

> All the examples assume that the `openapi_port` is the standard SSL port `443` . If your connectivity pool `openapi_port` has a different port setting, you must specify it in the request URL. For example, this URL specifies using port `8443` : `https://sql_node_address:8443/v1/execute/` .

Because `443` is a privileged port, the system applies this default value only when the `rolehostd` process runs as `root` or has the `CAP_NET_BIND_SERVICE` capability. Otherwise, the `openapi_port` remains unset, and you must configure it manually using this SQL statement.

### Enable or Change the OpenAPI Port

To open a port on a participant that does not already have one, or to change the port from its default, execute this **ALTER CONNECTIVITY POOL** SQL statement. Change the connectivity pool and node values in the example according to your system.

SQL

```
ALTER CONNECTIVITY_POOL benchmark_sql_connectivity_pool
    ALTER PARTICIPANT "benchmark-sql0" SET openapi_port 443;
```

## Check Port Configuration

Verify your port configuration by executing this query.

SQL

```
SELECT c.name, n.name, openapi_port
    FROM sys.connectivity_pool_participants AS cp
    LEFT JOIN sys.connectivity_pools AS c ON cp.id = c.id
    LEFT JOIN sys.nodes AS n ON cp.node_id = n.id;
```

The output displays all configured connectivity pools with their associated nodes and OpenAPI ports.

## SSL Certificate Setup

The Ocient® HTTP Query API supports two options for handling SSL certificates.

### Secure Connection Using TLS

You can use your own certificates for TLS-secured connections by configuring certificate files in your Ocient install. For details, see **Secure Connections Using TLS**.

### Unsecured Connection

For quick testing or in non-production environments, you can bypass certificate validation by adding the `-k` or `--insecure` flag to your curl command.

### Example

SQL

```
curl -k -u 'admin@system:admin' https://<sql-node-address>/v1/execute/system \
    -d '{"statement":"SELECT * FROM sys.dummy2;","format":"collection"}'
```

## Authentication Methods

The Ocient HTTP Query API accepts user credentials in various formats designed for different use cases.

### Simple API Requests

For simple queries, you can include user credentials in the request.

In this example, the request includes credentials after the `-u` flag.

CURL

```
curl -u 'admin@system:admin' https://sql_node/v1/execute/system \
    -d '{"statement":"SELECT * FROM sys.dummy2;", "format": "collection"}'
```

### Bearer Token Authentication

For continuous access, you can obtain an authentication token by making a request to the `login` endpoint. Replace the text in this example with the address of your SQL Node, your username, your password, and the name of your database.

CURL

```
curl -X POST https://sql_node/v1/login \
    -H "Content-Type: application/json" \
    -d '{
        "username": "admin@system",
        "password": "admin",
        "database": "system"
    }'
```

This request returns an authentication token that you can add to subsequent requests.

CURL

```
curl -X POST https://sql_node/v1/execute \
    -H "Authorization: Bearer TEST_ACCESS_TOKEN" \
    -H "Content-Type: application/json" \
    -d '{
        "statement": "SELECT * FROM sys.dummy2;",
        "database": "system",
        "format": "collection"
    }'
```

### OpenID Connect (SSO)

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

For SSO authentication, you can use OpenID Connect by targeting the `sso_authentication` endpoint with a callback path. Replace the text in this example with the name of your instance, the name of your database, and your callback path.

CURL

```
curl -X POST https://ocient-instance/v1/sso_authentication \
    -H "Content-Type: application/json" \
    -d '{
        "database": "system",
        "sso_callback_path": "/app_callback"
    }'
```

After the redirection and authentication are complete, you can include your token in subsequent requests.

CURL

```
curl -X POST https://ocient-instance/v1/sso_token \
    -H "Content-Type: application/json" \
    -d '{
        "id_token": "TEST_ID_TOKEN",
        "database": "system"
    }'
```

## API Endpoint Documentation

The Ocient HTTP Query API supports these endpoints.

For API requests, JSON data must use double quotes ( `"` ) for all keys and string values. Single quotes should enclose the JSON payload, as shown in this example (see the payload section following the `-d` flag).

CURL

```
curl -X POST \
    https://my_sql_node.com/v1/execute \
    -H "Content-Type: application/json" \
    -d '{ "query": "SELECT * FROM my_table WHERE status = \"active\"", "database'
```

Single or double quotes are acceptable for parameters not nested in JSON objects.

## Endpoints

**POST execute**

**GET execute**

**GET info**

**POST login**

**POST logout**

**POST sso_authentication**

**GET callback**

**POST sso_token**

**POST sso_device_grant**

**POST sso_device_grant_verify**

**POST token_refresh**

# execute

Executes a SQL statement and returns the results. Supports requests for both regular and streaming responses. With streaming, results return as they become available using the HTTP chunked transfer encoding. Each chunk contains a valid JSON object that you can parse independently. For details on streaming, including large-response configuration, see the header parameters. You can specify the database in the request body. If you do not specify the database, the Ocient System defaults to the database specified in the authentication token or system settings. If you specify a database in the request, this value overrides any alternate database value specified as a body parameter.

**POST** / v1 / execute / {database}

curl

cURL

```
curl -u 'admin@system:admin' https://my_sql_node.com/v1/execute/system \
    -d '{"statement":"SELECT * FROM sys.dummy2", "format": "collection"}'
```

200

```
{
  "query_id": "ac4dd039-e385-400b-a428-fd1fdcd02e30",
  "status": {
    "reason": "The operation completed successfully",
    "sql_state": "00000",
    "vendor_code": 0
  },
  "data": [
    {
      "c1": 1
    },
    {
      "c1": 2
    }
  ]
}
```

## Headers

**authorization** `string` `required`

An access token to connect to your Ocient System.

To receive an access token, you must provide your username and password using the login endpoint.

The system passes the credentials using the Authorization HTTP header using Base64-encoded Basic Authentication.

---

**content-type** `string` `required`

Specifies the request body format. Options include:

application/json

Description: The standard option for submitting queries and receiving responses as a single JSON object or array. Use when submitting queries with relatively small or moderate result sets or when you want the entire result set in one response.

application/stream+json

Description: Enables streaming of multiple JSON objects, allowing the API to send results as they become available. Use when querying large tables or expecting a large volume of results or when you want to process each row or result as soon as it is received, without waiting for the full response.

---

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### accept-encoding `string`

Supported compression algorithms for responses. You can specify multiple algorithms as a comma-separated list.

Supported values are:
"gzip"
"deflate"
"be" (Brotli)
or combinations like: "gzip, be".

Note: For large result sets, compression can impact performance. Without compression, the result sets can be chunks of rows processed in a streaming fashion. With compression, the entire result set must be compressed before it is returned to the client. The client side must decompress the entire result set before processing any rows.

---

### accept `string`

Supported response media types. Regardless of the Accept header, the API returns large query results using chunked encoding. Also, see the note about compression in the accept-encoding parameter.

Supported values are:

"application/json" (default)
"application/stream+json"

---

### preferred-encoding `string`

Indicates the preferred encoding type from those specified in the accept-encoding parameter. This header provides fine-grained control when the accept-encoding parameter contains multiple values, allowing the client to specify which encoding is preferred for this specific request explicitly.

Supported values are:

"gzip"
"br"

---

**preferred-compression-level** `integer`

Specifies the chosen compression level for the selected encoding algorithm. Values range from 1 (fastest, least compression) to 9 (slowest, maximum compression). The exact behavior depends on the specific compression algorithm.

## Path Parameters

**database** `string` `required`

The specific database in your system for the API call.

If you do not specify the database, the executed query defaults to the database from the authentication token or system settings.

If you include a database in the path, this value overrides any alternate database value specified as a body parameter.

## Query Parameters

**format** `string`

Sets the format for the requested data.

Note: This parameter applies only when using Content-Type: text/plain. When using Content-Type: application/json, specify the format in the request body.

Supported values are:

"array" — Returns schema and data as arrays (more efficient for large data sets). (default)
"collection" — Returns data as JSON objects (more convenient for client processing).

Example: format=collection

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

**schema** `string`

The schema to use for the SQL statement.

Example: schema=mydata

Note: This parameter applies only when using Content-Type: text/plain. When using Content-Type: application/json, specify the schema in the request body.

## Body

`application/json`

**statement** `string` `required`

A valid SQL statement to execute.

Example: statement=SELECT * FROM customers LIMIT 10;

You can include parameters to substitute in the SQL statement by including them in the params body parameter.

---

**database** `string`

A specific database in your system for the API call.

If you do not specify this parameter, the executed query defaults to the database from the authentication token or system settings.

---

**format** `string`

Sets the output format of the query result data.

Supported values are:

"array" — Returns the schema and data as arrays (more efficient for large data sets). (default)
"collection" — Returns data as JSON objects (more convenient for client processing).

---

**params** `object`

Parameters to substitute in the SQL statement for values enclosed in braces. The keys should match the parameter names in the statement (without the enclosing braces). Wrap string values in

© 2026 Ocient, Inc Ocient Proprietary and Confidential

single quotes. All other data types do not use quotes.

Example: If your SQL statement is SELECT * FROM orders WHERE order_date > {start_date}, then your API request should include values in the params body parameter, such as {'start_date': '2023-01-01'}.

---

**fetch_size** `integer`

The number of rows to return in each chunk for streaming responses. This value must be 0 or greater. A value of 0 (default) means the database determines how many rows to return.

Use smaller values for interactive applications (100-1000 rows). For batch processing, use larger values (5000-10000 rows).

---

**max_rows** `integer`

The maximum number of rows to return. The default value is 9223372036854776000.

Note: Adding a LIMIT clause to a SQL query is generally a better method to restrict the number of rows, as the query engine still generates the total number of rows, but only returns this value to the client.

## Response

200 - application/json

Response

**query_id** `string`

---

**status** `object`

Show child attributes

---

**data** `object[]`

Show child attributes

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# execute

Alternative GET method for executing SQL statements. This method passes parameters as URL query parameters. This method does not support the params body parameter. Specify which database to access in the query parameters. If you do not specify a database, the connection defaults to the database from the authentication token or system settings. This method is most suitable for simple, read-only queries where the statement can be safely included in a URL. For complex queries or those with parameters, use the POST method instead.

**GET** /v1/execute/{database}

curl

cURL

```
curl -u 'admin@system:admin' \

## Headers

**Authorization** `string` `required`

An access token to connect to your Ocient System.

To receive an access token, you must provide your username and password using the login endpoint.

The system passes the credentials using the Authorization HTTP header using Base64-encoded Basic Authentication.

---

**Content-Type** `string` `required`

Specifies the request body format. Options include:

application/json

Description: The standard option for submitting queries and receiving responses as a single JSON object or array. Use when submitting queries with relatively small or moderate result sets or when you want the entire result set in one response.

application/stream+json

Description: Enables streaming of multiple JSON objects, allowing the API to send results as they become available. Use when querying large tables or expecting a large volume of results or when you want to process each row or result as soon as it is received, without waiting for the full response.

---

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### accept-encoding `string`

Supported compression algorithms for responses. You can specify multiple algorithms as a comma-separated list.

Supported values are:
'gzip'
'deflate'
'br' (Brotli)
or combinations like: 'gzip, br'.

Note: For large result sets, compression can impact performance. Without compression, the result sets can be chunks of rows processed in a streaming fashion. With compression, the entire result set must be compressed before it is returned to the client. The client side must decompress the entire result set before processing any rows.

---

### accept `string`

Supported response media types. Regardless of the Accept header, the API returns large query results using chunked encoding. Also, see the note about compression in the accept-encoding parameter.

Supported values are:

"application/json" (default)
"application/stream+json"

---

### preferred-encoding `string`

Indicates the preferred encoding type from those specified in the accept-encoding parameter. This header provides fine-grained control when the accept-encoding parameter contains multiple values, allowing the client to specify which encoding is preferred for this specific request explicitly.

Supported values are:

"gzip"
"br"

---

**preferred-compression-level** `string`

Specifies the chosen compression level for the selected encoding algorithm. Values typically range from 1 (fastest, least compression) to 9 (slowest, maximum compression). The exact behavior depends on the specific compression algorithm.

## Path Parameters

**database** `string` `required`

The specific database in your system for the API call.

If you do not specify the database, the executed query defaults to the database from the authentication token or system settings.

If you include a database in the path, this value overrides any alternate database value specified as a body parameter.

## Query Parameters

**statement** `string` `required`

A valid SQL statement to execute. The statement must be URL-encoded, e.g., statement=SELECT%20*%20FROM%20customers%20LIMIT%2010%3B

**database** `string`

A specific database in your system for the API call.

If you do not specify the database, the executed query defaults to the database from the authentication token or system settings.

© 2026 Ocient, Inc

**format** `string`

Sets the response format.

Supported values are:

"array" — Returns the schema and data as arrays (more efficient for large data sets). (default)
"collection" — Returns data as JSON objects (more convenient for client processing).

---

**fetch_size** `string`

The number of rows to return in each chunk for streaming responses. This value must be 0 or greater. A value of 0 (default) means the database determines how many rows to return.

Use smaller values for interactive applications (100-1000 rows). For batch processing, use larger values (5000-10000 rows).

## Response

# sso_authentication

Initiates the OpenID Connect authentication process by redirecting to the authorization server. This endpoint begins the standard OpenID Connect authentication process: 1. The client calls this endpoint with a callback path. 2. The server responds with a redirect to the identity provider. 3. The user authenticates with the identity provider. 4. The identity provider redirects back to the callback endpoint. 5. The client can exchange the authorization code for an access token.

**POST** / v1 / sso_authentication

curl

cURL

```
curl -X POST https://my_sql_node.com/v1/sso_authentication \
    -H "Content-Type: application/json" \
    -d '{
        "database": "retail_analytics",
        "sso_callback_path": "/auth/callback",
        "do_redirect": true
    }'
```

200 404

```
{
  "status": {
    "reason": "Query executed successfully",
    "sql_state": "00000",
    "vendor_code": 0
  }
}
```

## Body

application/json

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

**database** `string`

Target database name. If you do not specify this parameter, the request defaults this value to system.

---

**sso_callback_path** `string`

Local path for redirection after successful authentication. This path should be registered with your OpenID provider as a valid redirect URI.

---

**do_redirect** `boolean`

Determines whether to issue the redirect to the authentication server immediately.

If you set this value to true (default), the API responds with a 302 redirect to the OpenID provider.

If you set this value to false, the API returns the URL in the response body, allowing the client to handle the redirect manually.

If you have no SSO configuration for the database, an error occurs if this parameter value is set to true. Otherwise, the request returns an empty redirect.

## Response

# callback

Provides the authentication token for the OpenID Connect authentication process. The authorization server redirects to callback path after successful authentication. This endpoint receives the authorization code from the OpenID provider and exchanges it for a token. The provider redirects the user to the application callback URL specified in the initial authentication request. The client application should not call this endpoint directly. The OpenID provider automatically calls this endpoint in the authentication process.

**GET** /v1/callback

curl

cURL

```
curl -X GET "https://my_sql_node.com/v1/callback?code=4/P7q7W91a-oMsCeLvIaQm6bTrgtp7&state=fRJ
```

200

```
{
  "status": {
    "reason": "Query executed successfully",
    "sql_state": "00000",
    "vendor_code": 0
  }
}
```

## Query Parameters

**code** `string` `required`

The authorization code from the OpenID provider. This endpoint exchanges the code for a token.

Example: code=4/P7q7W91a-oMsCeLvIaQm6bTrgtp7

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

**state** `string` `required`

Prevents cross-site request forgery attacks. This value should match the state in the initial authentication request.

Example: state=fRJfv29f3v39Jf39dJf93jf

# sso_token

Exchange an OpenID Connect identifier token or access token for an Ocient access token. This endpoint allows clients to directly exchange tokens without following the full browser-based authentication process. This exchange is useful for server-to-server scenarios or when the client already has a valid OpenID token from another process.

**POST** / v1 / sso_token

curl

cURL

```
curl -X POST https://my_sql_node.com/v1/sso_token \
    -H "Content-Type: application/json" \
    -d '{
        "id_token": "eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9...",
        "database": "retail_analytics"
    }'
```

200

```
{
  "id_token": "eyJhbGciOiJSUzI1NiIsInR5cCI6IkpXVCJ9...",
  "database": "retail_analytics"
}
```

## Body

application/json

**database** string required

Target database for connection after successful authentication. This database must be accessible to the user identified by the SSO token.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

**id_token** `string`

OpenID identifier token received from the OpenID provider after successful authentication. You must provide the id_token or access_token body parameters, but not both.

---

**access_token** `string`

OpenID access token received from the OpenID provider after successful authentication. You must provide the id_token or access_token body parameters, but not both.

## Response

# sso_device_grant

Retrieve an OpenID device grant code that the Ocient System can verify and use with the sso_device_grant_verify endpoint. The device grant process is intended for devices with limited input capabilities or no web browser: 1. Call this endpoint to retrieve a user code and verification URI. 2. Display the user code and verification URI to the user. 3. The user visits the verification URI on another device and enters the code. 4. Call the sso_device_grant_verify endpoint to check if the user has completed verification.

**POST** / v1 / sso_device_grant

curl

cURL

```
curl -X POST https://my_sql_node.com/v1/sso_device_grant \
    -H "Content-Type: application/json" \
    -d '{
        "database": "retail_analytics"
    }'
```

200

```
{
  "verification_uri_complete": "https://auth.example.com/device?code=BCDFGHJK",
  "verification_uri": "https://auth.example.com/device",
  "user_code": "BCDFGHJK",
  "status": {
    "reason": "Device authorization initiated",
    "sql_state": "00000",
    "vendor_code": 0
  }
}
```

## Body

application/json

# sso_device_grant_verify

Verify a previous device grant request and return an authorization token. After initiating a device grant process with the sso_device_grant endpoint, use this endpoint to check if the user has completed the verification process. If the verification is successful, the endpoint returns an authorization token that you can use for subsequent API calls. You can call this endpoint multiple times until one of these outcomes: The user completes the verification (returns 200 OK with a token). The timeout is reached (returns error). The verification is canceled (returns error).

**POST** / v1 / sso_device_grant_verify

curl cURL

```
curl -X POST https://my_sql_node.com/v1/sso_device_grant_verify \
    -H "Content-Type: application/json" \
    -d '{
        "user_code": "BCDFGHJK",
        "timeout": 60,
        "database": "retail_analytics"
    }'
```

200

```
{
  "access_token": "eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.eyJzdWIiOiJqZG9lIiwiZGIiOiJyZXRhaWxfYW
  "username": "jdoe",
  "database": "retail_analytics",
  "status": {
    "reason": "Authentication successful",
    "sql_state": "00000",
    "vendor_code": 0
  }
}
```

## Body

application/json

**user_code** `string` `required`

The user code returned from a previous device grant request using the sso_device_grant endpoint.

---

**database** `string`

Target database name. If you do not specify this parameter, the request defaults this value to system.

---

**timeout** `string`

The verification timeout, in seconds, indicates how long the server waits for the user to complete the device authorization process before returning a timeout error.

The default value is 30 seconds.

The valid range is 1-600 seconds (10 minutes).

## Response

# token_refresh

Refreshes an existing access token, extending its validity period. Call this endpoint before the current token expires to maintain uninterrupted access. Use the expires_in value from the login or previous refresh response to determine when to refresh the token. A common practice is to refresh when the token has half of its time remaining. On success, the endpoint returns the 200 response and a JSON object containing a new access token and metadata about the refreshed session. Replace the access token in your client with the new token returned by the endpoint, and use the expires_in value to decide when to refresh again.

**POST** / v1 / token_refresh

curl

cURL

```
curl -X POST https://your-ocient-instance/v1/token_refresh \
    -H "Authorization: Bearer YOUR_CURRENT_TOKEN" \
    -H "Content-Type: application/json" \
    -d '{
        "database": "retail_analytics"
    }'
```

200

```
{
  "access_token": "eyJhb...",
  "username": "jdoe",
  "database": "retail_analytics",
  "expires_in": 3600,
  "status": {
    "reason": "Token refreshed successfully",
    "sql_state": "00000",
    "vendor_code": 0
  }
}
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Headers

**Authorization** `string` `required`

The bearer token, which must be a valid access token still within its refresh lifetime configured on the server. To obtain a token, call either the /v1/login or /v1/token_refresh endpoints.

**Content-Type** `string` `required`

Specifies the request body format. Use the value: application/json.

## Body

`application/json`

**database** `string`

Target database name. If you do not specify this parameter, the request defaults this value to system.

# Understanding Data Types

Understand how Ocient stores and manipulates supported data types, including precision, range, storage size, and conversion across numeric and text values.

Ocient® supports many common data types such as INT, SHORT, DATE, and TIMESTAMP, as well as complex types like ARRAY and TUPLE, and specialized data types like POINT and LINESTRING used for geospatial analysis. For detailed information about supported data types, refer to the **Data Types** page.

You can use all these data types as types for columns in tables and for queries. Use scalar data conversion functions in queries to manipulate data types. For details, see **Scalar Data Conversion Functions**. You can execute various functions and aggregates depending on the data type. For example, you can sum, average, or process numeric types with other statistical functions, and you can trim, manipulate, or aggregate character types into a single string.

Basic data types such as INT, BOOLEAN, and VARCHAR behave similarly to other databases. You can query and inspect complex types, such as ARRAYS and TUPLES, like any other column, and also have special operators used to interrogate the sets of data.

## Numeric and Boolean Data Types

Numeric and Boolean types are used to represent data with different precision and scale. Integer values are supported from a one-byte signed int up to an eight-byte signed int. All integers are signed in Ocient. Floating point values are possible as either single or double precision, and exact decimal precision is available with the Decimal type. The Boolean type is used to represent true or false in the database.

All numeric types are fixed-length data types.

- BIGINT — eight-byte signed integer
- INT — four-byte signed integer
- SMALLINT — two-byte signed integer
- TINYINT — one-byte signed integer (alias: `BYTE`)

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- FLOAT — four-byte single precision floating-point number (alias: `REAL` or `SINGLE PRECISION`)
- DOUBLE — eight-byte double precision floating-point number (alias: `DOUBLE PRECISION`)
- DECIMAL(P,S) — Exact numerical decimal value with precision P and Scale S
- BOOLEAN — one-byte logical Boolean representing true or false

Learn more about working with numeric data types in the following sections:

- **Math Functions and Operators**
- **Scalar Data Conversion Functions**
- **Aggregate Functions**
- **Formatting Functions**

## Character and Binary Types

Character Types represent text and character data. Both fixed-length and variable-length options are available. Fixed-length provides some benefits to the database storage and query engine when applicable, but indexes are available that target variable-length character columns. Binary types represent byte array data.

- CHAR(N) — Variable-length character string with length N (alias: `CHARACTER(N)`)
- VARCHAR(N) — Variable-length character string with a maximum length of N
- BINARY(N) — Fixed-length binary array with length N (alias: `HASH(N)`)
- VARBINARY(N) — Variable-length binary array with maximum length N (alias: `HASH(N)`)

> The database ignores length of N for CHAR, VARCHAR, and VARBINARY. The database uses N for SQL conformance only.

Learn more about working with character and binary data types in these sections:

- **Character and Binary Functions**
- **Scalar Data Conversion Functions**

## Date and Time Types

Date and Time types are used to represent time in Ocient. Timestamps take on special capabilities when defined as a TimeKey® on a table. This is described in more detail in **TimeKeys and Clustering Keys**. Ocient provides many functions to operate on time series data.

- DATE — four-byte Calendar date representing year, month, day
- TIMESTAMP — eight-byte date and time with nanosecond precision in UTC time zone
- TIME — eight-byte time of day in nanoseconds

Learn more about working with date and time data types in the following sections:

- **Date and Time Functions**
- **Window Aggregate Functions**
- **Formatting Functions**

## Networking and Unique Identifier Types

Ocient provides data types for processing of IP addresses and UUIDs that allow schemas to leverage improved searching and analysis of both types as well as easier loading of structured data into these types. The IP type is designed for IP V6 and can handle IP V4 addresses as well.

- IPV4 — four-byte Internet Protocol V4 address
- IP — 16-byte Internet Protocol V6 address
- UUID — 16-byte universally unique identifier (e.g., *01234567-89ab-cdef-1357-0123456789ab*)

## Geospatial Data Types

Geospatial analysis is a rich capability in Ocient enabled by special data types and functions. The foundation rests on POINT, LINESTRING, and POLYGON types that represent respective points and shapes on the Earth. From these and composites of

these types, many proximity, intersection, and computational geospatial analytics can be performed at an incredible scale.

- POINT — Geometric point in two dimensions.
- LINESTRING — Geometric type composed of `N` POINTS.
- POLYGON — Geometric type composed of `N` closed LINESTRINGS.

Learn more about working with geospatial types in the **Geospatial Functions** section.

## Complex Types

Arrays and Tuples are SQL container types used to store other SQL types. These allow for complex schemas to be represented as a column in a table instead of separate, normalized tables. In some situations, using Arrays, Tuples, or Arrays of Tuples can lead to significant performance benefits. Use the Matrix type to store one or two-dimensional arrays of fixed-size data types for matrix computations.

- ARRAY — An array of any supported type other than ARRAY.
- MATRIX — A one or two-dimensional mathematical matrix used for matrix calculations.
- TUPLE — A tuple of elements of different types. Tuple is similar to a structure in other programming languages. You can include Tuples in arrays.

Learn more about complex data types in the following sections:

- **Array, Tuple, and Matrix Overview**
- **Array Functions and Operators**
- **Tuple Functions and Operators**
- **Matrix Functions and Operators**

# Array, Tuple, and Matrix Overview

Overview of array, tuple, and matrix data structures in Ocient SQL, with guidance on constructing, indexing, and operating on nested or composite values.

Arrays, tuples, and matrix data types are complex data types in the Ocient® System.

## Arrays

The array data type is a one-dimensional list of values with the same data type. This type enables the support of a one-to-many relationship without creating another table. You create secondary indexes on arrays, which index the elements of the array. For details about secondary indexes, see **Secondary Indexes**.

Key features:

- Variable size.
- Can contain many elements.
- Indexing into the array starts at `1`.
- Invalid access of the array returns NULL.

For semi-structured data in JSON format, you can express the JSON multi-value column in an array data type. Traditionally in the normalized relational data model, the database represents such data types as a separate table. Each row stores the value of the primary key of the record in the parent table. Therefore, the entity relationship between the tables is always one-to-many, which can result in billions of rows. The array data type eliminates the child tables, which helps reduce the storage footprint and avoids the additional JOIN operations.

### Examples

Create a one-dimensional integer array `[1, 2, 3]` using the `sys.dummy` virtual table.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT INT[](1,2,3)
FROM sys.dummy1;
```

*Output*

Text

```
array_int(int((1)), int((2)), int((3)))
---------------------------------------
[1,2,3]

Fetched 1 row
```

Create a two-dimensional integer array `[[1, 2, 3], [4, 5, 6]]`.

SQL

```
SELECT INT[][](INT[](1,2,3),INT[](4,5,6))
FROM sys.dummy1;
```

*Output*

Text

```
array_array(int)(array_int(int((1)), int((2)), int((3))), array_int(int((4)), int
---------------------------------------------------------------------------------
[[1,2,3],[4,5,6]]

Fetched 1 row
```

You can get the same result by casting the array and integers explicitly.

SQL

```
SELECT INT[][](ARRAY[INT(1),INT(2),INT(3)],ARRAY[INT(4),INT(5),INT(6)])
FROM sys.dummy1;
```

For more examples, see **Array Functions and Operators**.

# Tuples

The tuple data type is a row. This type is a fixed-sized collection of heterogeneous values. Tuples support more complex recursive computational functions. The memory structure of the tuple is identical to the memory structure of the array type. The only difference is that each entry in a tuple can be any type, so the Ocient System can simultaneously store both fixed and variable-sized values in a tuple.

### Examples

Create a tuple with fixed-size types. In this case, use three integers.

SQL

```
SELECT TUPLE(1,2,3)
FROM sys.dummy1;
```

*Output*

Text

```
tuple((1), (2), (3))
--------------------------------------------------------------------------------
<<1, 2, 3>>

Fetched 1 row
```

You can get the same result by using the tuple type constructor.

SQL

```
SELECT TUPLE<<INT,INT,INT>>(1,2,3)
FROM sys.dummy1;
```

Create a tuple with variable-size types. In this case, use a one-dimensional and two-dimensional array.

SQL

```
SELECT TUPLE(ARRAY[INT(1),INT(2),INT(3)],
    INT[][](ARRAY[INT(1),INT(2),INT(3)],ARRAY[INT(4),INT(5),INT(6)]))
FROM sys.dummy1;
```

*Output*

Text

```
tuple(array_int(int((1)), int((2)), int((3))), array_array(int)(array_int(int((1)
--------------------------------------------------------------------------------
<<[1,2,3], [[1,2,3],[4,5,6]]>>

Fetched 1 row
```

Create a tuple with different types. In this case, an integer, string, and array of integers.

SQL

```
SELECT TUPLE<<INT,VARCHAR,INT[]>>(1, 'test_string', INT[](2,4,6))
FROM sys.dummy1;
```

*Output*

Text

```
tuple(int((1)), ('test_string'), array_int(int((2)), int((4)), int((6))))
--------------------------------------------------------------------------------
<<1, test_string, [2,4,6]>>

Fetched 1 row
```

For more examples, see **Tuple Functions and Operators**.

# Matrices

A matrix is a fixed-size two-dimensional array of `DOUBLE` values. A matrix can be a row vector (1xN matrix) or column vector (Nx1 matrix).

matrices support machine learning model calculations. For details, see **Machine Learning in Ocient**.

### Examples

Create a 1x4 matrix with numbers 1 through 4 using the `make_matrix` function that expects values in row-major order. The first two arguments indicate the dimensions of the matrix, and the remaining arguments specify the values for the matrix.

SQL

```sql
SELECT make_matrix_1x4(1,4,1,2,3,4)
FROM sys.dummy1;
```

*Output*

Text

```
make_matrix_1x4((1), (4), (1), (2), (3), (4))
--------------------------------------------------------------------------------
[[1.0,2.0,3.0,4.0]]

Fetched 1 row
```

Create a 2x3 matrix with numbers 1 through 6.

SQL

```
SELECT make_matrix_2x3(2,3,1,2,3,4,5,6)
FROM sys.dummy1;
```

*Output*

Text

```
make_matrix_2x3((2), (3), (1), (2), (3), (4), (5), (6))
--------------------------------------------------------------------------------
[[1.0,2.0,3.0],[4.0,5.0,6.0]]

Fetched 1 row
```

Create a row vector with four doubles.

SQL

```
SELECT _R{1,2,3,4}
FROM sys.dummy1;
```

*Output*

Text

```
_r{1,2,3,4}
--------------------------------------------------------------------------------
[[1.0,2.0,3.0,4.0]]

Fetched 1 row
```

For more examples, see **Matrix Functions and Operators**.

# Functions Overview

Explore Ocient function library for data analysis, manipulation, and transformations, empowering complex querying and calculations.

Ocient® includes many functions for statistics, mathematics, string manipulation, and working with complex types like Arrays and geospatial data. The following types of functions are supported:

## SQL Functions

### Math and Arithmetic Functions

Perform mathematical operations on data in Ocient, including basic operators on data types and advanced statistical functions.

- **Math Functions and Operators**
- **Aggregate Functions**

### Character and Binary Functions

Manipulate character strings and binary data types and use character operators to query character data.

- **Character and Binary Functions**

### Conversion and Formatting Functions

Convert data types with scalar conversions and format numbers and times in character outputs.

- **Scalar Data Conversion Functions**
- **Formatting Functions**

### Date and Time Functions

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Perform date operations in Ocient, including manipulation and comparison of date and time types. Date and Time functions allow users to add, subtract, and truncate date time values and intervals.

- **Date and Time Functions**
- **Time Zone Functions**

## Aggregates

Aggregates include basic aggregates and sorted aggregates that combine many rows into a single result, as well as window aggregates that combine information from multiple rows within the window into each row in the result set.

- **Aggregate Functions**
- **Window Aggregate Functions**
- **HyperLogLog Functions**

## Array, Tuple, and Matrix Functions

Special functions and operators to work with container types. These include operators to check set logic, slice, compare, and manipulate arrays, tuples, and matrices.

- **Array Functions and Operators**
- **Tuple Functions and Operators**
- **Matrix Functions and Operators**

## Geospatial Functions

Functions and Operators to manipulate and compare points, linestrings, and polygons.

- **Geospatial Functions**

## Network Functions

Functions for using network data types, including `IP` and `IPV4`.

- **Network Type Functions**

### Miscellaneous Functions

A set of functions such as `CASE`, `CURRENT_USER`, and `NULL_IF` that provide additional capabilities in Ocient.

- **Other Functions and Expressions**

# Text Analysis in Database Queries

Use Ocient text analysis SQL functions for tokenization, stemming, search, and pattern matching to extract insights from text columns at large scale.

The OcientAIQ™ Unified Data Platform enables search and analysis of textual data. You can run queries efficiently using indexes in the OcientAIQ Unified Data Platform to perform text analysis. The database supports different types of indexes. The N-gram index is a type of secondary index that enables text analysis.

### Cluster Key Indexes

Define cluster key (CK) indexes when you create the table.

| Index Type | Number of Columns | Column Types | Filters |
|---|---|---|---|
| Primary CK index (always exists) | Multiple | Fixed-length or GDC columns, fixed-length tuple columns | Equality-like, range |
| Additional CK indexes | Subset of CK in any order | | |

### Secondary Indexes

You can create or drop secondary indexes at any time.

| Index Type | Number of Columns | Column Types | Filters |
|---|---|---|---|
| Inverted indexes | Single | Fixed-length or GDC column, array, or tuple component | Equality-like, range |
| Hash indexes | | Variable-length column, array, or tuple component | Equality-like |
| N-gram indexes | | VARCHAR column, array, or tuple component | LIKE, equality-like |

N-gram indexes support text analysis by providing an efficient search of textual data. This type of index works by tokenizing the pattern in the string, and then pruning and

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

transforming the tokens. You can create N-gram indexes at any time. For details about creating an N-gram index, see **CREATE INDEX**.

There are other ways to perform text analysis. For details, see the syntax for **LIKE** and **SIMILAR TO**.

# Machine Learning in Ocient

Integrate machine learning models into Ocient queries with OcientML for advanced data analysis, empowering predictive and classification insights.

The OcientAIQ™ Unified Data Platform has OcientML™ functionality that enables machine learning training and model execution within the database. Whether you are training a model or using machine learning functionality to do scoring or prediction, OcientML enables machine learning in the SQL syntax directly.

You can use the `CREATE MLMODEL` SQL statement to create models. This step is for model training and is referred to as model creation. Similarly, you can use the model on new input data to generate new predictions by executing the scalar function that has the same name as the model. This action is typically referred to as executing the model.

Machine learning in Ocient® depends upon linear algebra functionality that is built into the Ocient System. OcientML provides machine learning capabilities that you can invoke in SQL statements with some application logic.

## Linear Algebra in Ocient

matrices are a first-class data type in the Ocient System. Create a matrix using a simple SQL SELECT statement.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT {{1, 2}, {3, 4}};
{{1,2},{3,4}}
--------------------------------------------------------------------------------
[[1.0, 2.0], [3.0, 4.0]]

Fetched 1 row

SELECT {{c1*1, c1*2}, {c1*3, c1*4}} FROM sys.dummy2;
make_matrix_2x2((2), (2), ((1))*(c1), ((2))*(c1), ((3))*(c1), ((4))*(c1))
--------------------------------------------------------------------------------
[[1.0, 2.0], [3.0, 4.0]]
[[2.0, 4.0], [6.0, 8.0]]

Fetched 2 rows
```

You can also use shorthand notations to create row `_r` or column vectors `_c`. For example, `_r{1,2,3}` creates a row vector with values `1.0`, `2.0`, and `3.0`.

SQL

```
SELECT _r{1,2,3};
_r{1,2,3}
--------------------------------------------------------------------------------
[[1.0, 2.0, 3.0]]

Fetched 1 row

SELECT _c{1,2,3};
_c{1,2,3}
--------------------------------------------------------------------------------
[[1.0], [2.0], [3.0]]

Fetched 1 row
```

You can execute functions using the values in the vectors. This query does some matrix arithmetic, finds the inverse matrix, and then returns the two eigenvalues and eigenvectors of the inverse.

SQL

```
SELECT EIGEN(INVERSE(2 * {{1,2},{3,4}} + {{5,6},{7,8}} / 2));
EIGEN(INVERSE((((2))*({{1,2},{3,4}}))+(({{5,6},{7,8}})/((2)))))
--------------------------------------------------------------------------------
[<<-1.3780529228406495, [[0.8013353799887076, -0.5982153531783962]]>>, <<0.058052

Fetched 1 row
```

## Machine Learning Models

Ocient supports regression, classification, and clustering models. Also, Ocient supports models for dimensionality reduction. For guides on using the different OcientML models, see:

- **Regression Analysis**
- **Classification Analysis**
- **Clustering Analysis and Dimensionality Reduction**

**Machine Learning Model Functions**

**Regression Models**

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# Regression Analysis

Apply regression analysis within Ocient with OcientML to understand relationships in data and make predictions based on historical trends.

OcientML™ enables regression analysis, which is the process of finding a best-fit function for a data set, in the Ocient® System.

## Simple Linear Regression

The simplest case is simple linear regression. Simple linear regression finds a best-fit linear relationship between one variable and another.

Suppose you have this data with a bit of noise added. Use the `CREATE TABLE AS SELECT` SQL statement to create the `mldemo.slr` table. Generate 100 rows of random data.

SQL

```
CREATE TABLE mldemo.slr AS
(SELECT c1 AS x, c1 * 3.14 - 1.41 + (RAND() - 0.5) * 0.01 AS y
FROM sys.dummy100);
Modified 100 rows
```

Create a simple linear regression model using this data.

SQL

```
CREATE MLMODEL my_first_model TYPE SIMPLE LINEAR REGRESSION
ON (SELECT x, y FROM mldemo.slr);
```

Explore the created model by viewing the data in the `machine_learning_models` and `simple_linear_regression_models` system catalog tables.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT name, on_select, slope, y_intercept
FROM sys.machine_learning_models a, sys.simple_linear_regression_models b
WHERE a.id = b.machine_learning_model_id AND name = 'my_first_model';
name                                          on_select
-------------------------------------------------------------------------------
my_first_model                                select x, y from mldemo.slr

Fetched 1 row
```

You can see the calculated slope and the y-intercept from the model, and see that these values are very close to the values used to generate the data. While the input to the model creation, in this case, is very simple, the SQL statement in the ON clause of the model creation can be arbitrarily complex as long as it meets the requirements of the input for the specific model type being created.

Execute the created model by executing the SQL scalar function with the same name as the model you created. The input arguments of the function depend on the specific model type. For regression, the values are the independent variables, and then the function returns the dependent variables.

SQL

```
SELECT x, y AS actual, my_first_model(x) AS predicted FROM mldemo.slr LIMIT 10;
x           actual                 predicted
-----------------------------------------------------
51          158.730137908257       158.72952690917217
52          161.87052128169267     161.8695223592868
53          165.0119331158625      165.00951780940144
54          168.1478263920115      168.14951325951608
55          171.28758882396247     171.28950870963072
56          174.43476312079238     174.42950415974536
57          177.57385971080322     177.56949960986
58          180.70933136639127     180.70949505997464
59          183.84856961481378     183.84949051008925
60          186.99044288540566     186.9894859602039

Fetched 10 rows
```

The model makes predictions that are very close to the actual training data. Then, you can use this data to generate predictions for data that is unknown.

## Machine Learning Model Options

You can provide options for most model types. Provide options by pairing the string for an option to its corresponding value. For example, simple linear regression models have a `metrics` option that you can use to ask the database to calculate some quality of fit metrics. Use the same model and enable metrics collection, which is off by default.

SQL

```
DROP MLMODEL my_first_model;
Modified 0 rows

CREATE MLMODEL my_first_model TYPE SIMPLE LINEAR REGRESSION
ON (SELECT x, y FROM mldemo.slr) options('metrics' -> 'true');
Modified 0 rows
```

Examine the `machine_learning_models` and `simple_linear_regression_models` system catalog tables for more fields.

SQL

```
SELECT name, on_select, slope, y_intercept, coefficient_of_determination,
adjusted_r2, rmse FROM sys.machine_learning_models a, sys.simple_linear_regressio
WHERE a.id = b.machine_learning_model_id AND name = 'my_first_model';
name                                          on_select
-------------------------------------------------------------------------------
my_first_model                                select x, y from mldemo.slr

Fetched 1 row
```

The database also calculates the coefficient of determination (frequently named r2), the adjusted r2 value, and the RMSE (root mean squared error). All of these values indicate that this model has an extremely good fit.

In addition, you can force a specific y-intercept such that the value of `f(0)` is fixed. Use the `yIntercept` option. Create a model on the same data, but force the y-intercept

to be zero. The metrics show that the model is not as good a fit as when the intercept is free to vary.

SQL

```
CREATE MLMODEL force_zero TYPE SIMPLE LINEAR REGRESSION
ON (SELECT x, y FROM mldemo.slr) options('metrics' -> 'true', 'yIntercept' -> '0'
Modified 0 rows

SELECT name, on_select, slope, y_intercept, coefficient_of_determination,
adjusted_r2, rmse FROM sys.machine_learning_models a, sys.simple_linear_regressio
WHERE a.id = b.machine_learning_model_id AND name = 'force_zero';
name                                              on_select
-------------------------------------------------------------------------------
force_zero                                        select x, y from mldemo.slr

Fetched 1 row
```

## Multiple Linear Regression

In multiple linear regression, the model is still predicting an output value. But instead of handling one input variable, the model can handle an arbitrary number of input variables. Multiple linear regression finds the best-fit model of the form:

Text

```
y = a1x1 + a2x2 + a3x3 + … + a0
```

Simple linear regression and multiple linear regression (as well as polynomial regression and linear combination regression) all use a least-squares loss function. Some of the more advanced models allow you to define best fit yourself if the default definition is not satisfactory. Least-squares best fit means that the model minimizes the sum (over all training data rows) of the square of the model error.

Create a training data set with some noise and show that the model can reconstruct the data. Multiple linear regression models also support a metrics option (the metrics are the same as simple linear regression).

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE TABLE mldemo.mlr AS (SELECT a.c1 AS x1, b.c1 AS x2, 1 + 2*a.c1 + 3*b.c1 AS
FROM sys.dummy10 a, sys.dummy10 b);
Modified 100 rows

CREATE MLMODEL mlr_model TYPE MULTIPLE LINEAR REGRESSION ON (SELECT * FROM mldemo
options('metrics' -> 'true');
Modified 0 rows

SELECT x1, x2, y AS actual, mlr_model(x1, x2) AS predicted FROM mldemo.mlr LIMIT
x1          x2          actual                predicted
------------------------------------------------------------
6           1           16                    15.999999999999975
6           2           19                    18.999999999999975
6           3           22                    21.999999999999975
6           4           25                    24.999999999999975
6           5           28                    27.999999999999975
6           6           31                    30.999999999999975
6           7           34                    33.99999999999997
6           8           37                    36.99999999999997
6           9           40                    39.99999999999997
6           10          43                    42.99999999999997

Fetched 10 rows
```

## Polynomial Regression

With polynomial regression, the database finds a least-squares best-fit polynomial of whatever degree you specify. Same as multiple linear regression, you determine the number of independent variables.

The training data has a `1/(x1 * x2)` term that the model does not match, but that term quickly tends towards zero, so the model should provide a good fit with a quadratic polynomial of `x1` and `x2`. Some of the coefficients match the data, but some do not because the model is compensating for not being able to fit the form of the data exactly. However, the metrics indicate that this model is still a great fit.

SQL

```
CREATE TABLE mldemo.pr AS
(SELECT x1, x2, 1.0 / (x1 * x2) - 2*x1 - 0.5*x1*x2 + 2.3*x1^2 + 1.1*x2^2 AS y
FROM (SELECT a.c1 AS x1, b.c1 AS x2 FROM sys.dummy10 a, sys.dummy10 b));
Modified 100 rows

CREATE MLMODEL pr1 TYPE POLYNOMIAL REGRESSION
ON (SELECT * FROM mldemo.pr) options('order' -> '2', 'metrics' -> 'true');
Modified 0 rows

SELECT name, on_select, num_arguments, coefficient_of_determination,
adjusted_r2, rmse, y_intercept, coefficients
FROM sys.machine_learning_models a, sys.polynomial_regression_models b
WHERE a.id = b.machine_learning_model_id AND name = 'pr1';
name                                          on_select
-----------------------------------------------------------------------------
pr1                                           select * from mldemo.pr

Fetched 1 row
```

Polynomial regression models have many available options, including everything available for multiple linear regression. The `negativePowers` option enables you to fit Laurent polynomials. If you set this option to `true`, the model includes independent variables raised to negative powers. Sums of such terms are named Laurent polynomials. The model generates all possible terms such that the sum of the absolute value of the power of each term in each product is less than or equal to the order.

For example, with two independent variables and the order set to 2, the model is:

`y = a1*x1^2 + a2*x1^-2 + a3*x2^2 + a4*x2^-2 + a5*x1*x2 + a6*x1^-1*x2 + a7*x1*x2^-1 + a8*x1^-1*x2^-1 a9*x1 + a10*x1^-1 + a11*x2 + a12*x2^-1 + b`

SQL

```
CREATE TABLE mldemo.pr_negativepowers AS
(SELECT x1, x2, 1.0 + 12*x2^-1 - 11*x2 + 10*x1^-1 + 9*x1 + 8*(x1 - 1)*(x2 - 1) +
7*x1*x2^-1 + 6*x1^-1*x2 + 5*x1*x2 + 4*x2^-2 + 3*x2^2 + 2*x1^-2 + x1^2 AS y
FROM (SELECT a.c1 AS x1, b.c1 AS x2 FROM sys.dummy10 a, sys.dummy10 b));
Modified 100 rows

CREATE MLMODEL pr2 TYPE POLYNOMIAL REGRESSION
ON (SELECT * FROM mldemo.pr_negativepowers)
options('order' -> '2', 'metrics' -> 'true', 'negativePowers' -> 'true');
Modified 0 rows

SELECT name, on_select, num_arguments, coefficient_of_determination,
adjusted_r2, rmse, y_intercept, coefficients
FROM sys.machine_learning_models a, sys.polynomial_regression_models b
WHERE a.id = b.machine_learning_model_id AND name = 'pr2';
name                                          on_select
-------------------------------------------------------------------------------
pr2                                           select * from mldemo.pr
```

You can see that now the model almost perfectly recovers the coefficients, with the rest being nearly zero.

Execute the `pr2` model.

SQL

```
SELECT x1, x2, y AS actual, pr2(x1, x2) AS predicted FROM mldemo.pr LIMIT 10;
x1                    x2                    actual                predicted
--------------------------------------------------------------------------------

Fetched 10 rows
```

## Linear Combination Regression

The most complex type of linear regression that Ocient supports is linear combination regression. This regression is a generalization of polynomial regression. Polynomial regression tries to find the best linear combination of polynomial terms ( `x1` , `x2` , `x1^2` , `x2^2` , `x1*x2` , and so on). Linear combination regression finds the best fit linear combination, where you can specify all the terms.

Assume this training data. Use the `CREATE TABLE AS SELECT` SQL statement to create the `mldemo.lcr` table. Generate 1000 rows of data.

SQL

```
CREATE TABLE mldemo.lcr AS
(SELECT x1, x2, x3, 10.0 * sin(x1) + 2.0 * cos(x2) - 3.0 * MOD(INT(x1)*INT(x2)*IN
AS y FROM (SELECT a.c1 AS x1, b.c1 AS x2, c.c1 AS x3
FROM sys.dummy10 a, sys.dummy10 b, sys.dummy10 c));

```

The coefficient of determination shows that the model is not a bad fit, but the fit is not great due to the structure of the data. However, given that the model is still a linear combination of functions, linear combination regression can recover the fit if you specify the functions to use.

SQL

```
CREATE MLMODEL lcr1 TYPE LINEAR COMBINATION REGRESSION
ON (SELECT x1, x2, x3, y FROM mldemo.lcr) options('function1' -> 'sin(x1)',
'function2' -> 'cos(x2)', 'function3' -> 'mod(int(x1)*int(x2)*int(x3),4)',
'metrics' -> 'true');
Modified 0 rows

SELECT name, on_select, num_arguments, coefficient_of_determination,
adjusted_r2, rmse, y_intercept, coefficients
FROM sys.machine_learning_models a, sys.linear_combination_regression_models b
WHERE a.id = b.machine_learning_model_id AND name = 'lcr1';
name                                          on_select
-------------------------------------------------------------------------------
lcr1                                          select x1, x2, x3, y from mldemo.lcr

Fetched 1 row
```

You can see that the model finds the coefficients perfectly and has a coefficient of determination of 1.0.

The coefficient of determination represents the amount of variance in the data explained by the model. A coefficient of determination of 1.0 indicates that all the variance is explained and that the model is a perfect fit. A coefficient of determination of 0.0 indicates that none of the variance is explained. A negative coefficient of determination is possible, but you do not find it in linear regression models because these models always find a fit that is at least as good as the constant function (the average of all the training data). That model has a coefficient of determination of 0.0.

## Non-Linear Regression

The non-linear regression model is similar to linear combination regression in that you define the form of the model. However, non-linear regression can be more than a linear combination of terms.

Assume this training data. Use the `CREATE TABLE AS SELECT` SQL statement to create the `mldemo.nlo_input1` table. Generate 100 rows of data. Then, create a non-linear regression model using five parameters.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE TABLE mldemo.nlo_input1 AS (
    SELECT x1,
        x2,
        2.0 * sin(3.0 * x1 - 1.0) - 4.0 + 5.0 * x2 as y
    FROM (
            SELECT a.c1 / 4.0 as x1,
                b.c1 / 4.0 as x2
            FROM sys.dummy10 a,
                sys.dummy10 b
        )
);
Modified 100 rows

CREATE mlmodel nlo1 TYPE NONLINEAR REGRESSION ON (
    SELECT x1,
        x2,
        y
    FROM mldemo.nlo_input1
) options(
    'numParameters'->'5',
    'function'->'a1 * SIN(a2 * x1 + a3) + a4 + a5 * x2',
    'metrics'->'true'
);
Modified 0 rows
```

In this case, specify only one function that covers the whole model.

Use the `machine_learning_models` and `nonlinear_regression_models` system catalog tables to see the metrics and the values that the model chose.

SQL

```
SELECT name,
    on_select
FROM sys.machine_learning_models a,
    sys.nonlinear_regression_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'nlo1';

name                                                on_select
--------------------------------------------------------------------------------
nlo1                                                select x1, x2, y from mldemo.nlo_inp

Fetched 1 row
```

If you look at the coefficients, you can see the amplitude (2.0) is negative in the model, but that is offset by subtracting pi from the phase. The model still almost exactly matches how the data is generated, but it just found a slightly different, but equivalent, way of doing it.

Non-linear regression models (and all of the other models that use the same infrastructure) have lots of options that control how the search works. These options affect the length of time it takes for training the model, but they also affect the likelihood of getting stuck in a global minimum. The model chooses default values such that they should be sufficient for a wide range of use cases.

With non-linear regression models, you can specify a loss function other than least-squares. In this example, specify the `abs(f-y)` loss function.

© 2026 Ocient, Inc

SQL

```
CREATE MLMODEL nlo2 type NONLINEAR REGRESSION ON (
    SELECT x1,
        x2,
        y
    FROM mldemo.nlo_input1
) options(
    'numParameters'->'5',
    'function'->'a1 * sin(a2 * x1 + a3) + a4 + a5 * x2',
    'lossFunction'->'abs(f-y)'
);
Modified 0 rows
```

In this case, find the best fit that minimizes the sum of the absolute value of the model errors instead of the sum of the square of the model errors. The variable `f` represents the value of the model, and the variable `y` represents the actual value in the training data.

The catalog indicates the model is nearly the same as the previous model. In other words, changing the loss function here did not substantially change anything. But there are cases where other loss functions are appropriate and they could substantially change the model.

## Non-Linear Regression with Neural Networks

In all of the non-linear cases, you have to make a good guess for the form of the target function. However, with neural networks, you can leave it up to the network to try to figure out that form. The downside is that aspects of the model are a black box.

This example uses the same example as non-linear regression, but instead of specifying the form of the function, it relies on what the neural net can do with little information. The size of the network layers and the number of layers greatly influence how good of a fit a neural net model has. This example uses a simple network.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE MLMODEL nn1 TYPE FEEDFORWARD NETWORK ON (
    SELECT x1,
        x2,
        y
    FROM mldemo.nlo_input1
) options(
    'metrics'->'true',
    'hiddenLayers'->'2',
    'hiddenLayerSize'->'2',
    'outputs'->'1',
    'lossFunction'->'squared_error'
);
Modified 0 rows
```

In the case of neural network models, the metric used is an average loss because RMSE and the coefficient of determination are generally only appropriate for least squares models, and neural networks might be using other loss functions.

You can see the average loss by querying the `machine_learning_models` and `feedforward_network_models` system catalog tables.

SQL

```
SELECT name,
    on_select,
    num_arguments,
    average_loss
FROM sys.machine_learning_models a,
    sys.feedforward_network_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'nn1';

name                                          on_select
-------------------------------------------------------------------------------
nn1                                           select x1, x2, y from mldemo.nlo_inp

Fetched 1 row
```

Compute the coefficient of determination manually.

```sql
SELECT AVG(y)
FROM mldemo.nlo_input1;

(sum(y))/(null_if(double(count(y)), (0)))
------------------------------------------
2.8698217335180987

Fetched 1 row

SELECT 1.0 - SUM((nn1(x1, x2) - y) ^ 2) / SUM((y - 2.8698217335180987) ^ 2) AS r2
FROM mldemo.nlo_input1;

r2
----------------------
0.9981701280250409

Fetched 1 row
```

This model fits the data very well.

## Vector-Valued Regression

Vector-valued regression is the case where the dependent variable has multiple components. You can use any type of model to learn each component separately, or you can use a feedforward network to learn all components in one model.

The example creates 100 rows of sample data.

SQL

```
CREATE TABLE mldemo.vector_valued AS (
    SELECT x1,
        { { 2 * x1 + 3,
        3 * x1 -2 } } as y
    FROM (
            SELECT c1 AS x1
            FROM sys.dummy100
        )
);
Modified 100 rows
```

There is a dependent variable that depends on `x1`, which is vector-valued. Each component can fit a linear model, which can then predict vector-valued results.

SQL

```
CREATE MLMODEL vv1 TYPE SIMPLE LINEAR REGRESSION ON (
    SELECT x1,
        y [1,1]
    FROM mldemo.vector_valued
);
Modified 0 rows

CREATE MLMODEL vv2 TYPE SIMPLE LINEAR REGRESSION ON (
    SELECT x1,
        y [1,2]
    FROM mldemo.vector_valued
);
Modified 0 rows
```

The query verifies that it produces reasonable results.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT x1,
    y AS actual,
    { { vv1(x1),
    vv2(x1) } } AS predicted
FROM mldemo.vector_valued
LIMIT 10;

x1         actual
-------------------------------------------------------------------------------
51         [[105.0, 151.0]]
52         [[107.0, 154.0]]
53         [[109.0, 157.0]]
54         [[111.0, 160.0]]
55         [[113.0, 163.0]]
56         [[115.0, 166.0]]
57         [[117.0, 169.0]]
58         [[119.0, 172.0]]
59         [[121.0, 175.0]]
60         [[123.0, 178.0]]

Fetched 10 rows
```

This example shows that a single model can perform this with the feedforward network model type.

SQL

```
CREATE MLMODEL vv3 TYPE FEEDFORWARD NETWORK ON (
    SELECT x1,
        y
    FROM mldemo.vector_valued
) options(
    'hiddenLayers'->'2',
    'hiddenLayerSize'->'2',
    'outputs'->'2',
    'lossFunction'->'vector_squared_error'
);
Modified 0 rows
```

`outputs`, which is set to the size of the vector, and the `lossFunction` option is set to use `vector_squared_error`.

This example shows how well the model can predict the output.

SQL

```
SELECT x1,
    y AS actual,
    vv3(x1) AS predicted
FROM mldemo.vector_valued
LIMIT 10;

x1          actual
-------------------------------------------------------------------------------
51          [[105.0, 151.0]]
52          [[107.0, 154.0]]
53          [[109.0, 157.0]]
54          [[111.0, 160.0]]
55          [[113.0, 163.0]]
56          [[115.0, 166.0]]
57          [[117.0, 169.0]]
58          [[119.0, 172.0]]
59          [[121.0, 175.0]]
60          [[123.0, 178.0]]

Fetched 10 rows
```

## Autoregression

Autoregression is linear regression where the independent variables are lags of the dependent variable. In other words, it is a series where the next value depends linearly on the previous N values.

These examples do not use a new model type. Instead, they use multiple linear regression models.

One of the important things about autoregression is that some variables indicate the order of the data. This variable can be a time variable, but it does not need to be. This

variable is necessary to correctly set up the model, but it is not directly used by the model. Instead, the variable helps build the correct lags.

This example builds a model to predict the Fibonacci sequence. This statement creates a table with the first several Fibonacci terms.

SQL

```
CREATE TABLE mldemo.fib AS (
    SELECT 0 AS t,
        0 AS f
    UNION ALL
    SELECT 1,
        1
    UNION ALL
    SELECT 2,
        1
    UNION ALL
    SELECT 3,
        2
    UNION ALL
    SELECT 4,
        3
    UNION ALL
    SELECT 5,
        5
    UNION ALL
    SELECT 6,
        8
    UNION ALL
    SELECT 7,
        13
    UNION ALL
    SELECT 8,
        21
    UNION ALL
    SELECT 9,
        34
);
Modified 10 rows
```

This example builds a model where the dependent variable depends on two lags.

SQL

```
CREATE MLMODEL fib TYPE MULTIPLE LINEAR REGRESSION ON (
    SELECT LAG(f, 1) OVER(
            ORDER BY t
        ),
        LAG(f, 2) OVER(
            ORDER BY t
        ),
        f
    FROM mldemo.fib
);
Modified 0 rows
```

When you execute the model, which provides the model with two lags, the model can predict the next value of the sequence that is not in the data, `55`.

SQL

```
SELECT fib(21, 34);

((((1.0000000000001137))*((21)))+((1.4210854715202004e-14)))+(((1))*((34)))
-------------------------------------------------------------------------
55.0000000000024

Fetched 1 row
```

## Vector Autoregression

Vector autoregression is just a more complex version of autoregression. This model uses multiple time series, where the next value for each time series depends linearly on the lags of all of the time series.

This statement sets up some data where the next value for two time series depends on the previous two values of both time series.

SQL

```
CREATE TABLE mldemo.var_input AS (
    SELECT 3.1415 AS s1,
        1.4142 AS s2,
        0 AS t
    UNION ALL
    SELECT 2.7182 AS s1,
        1.618 AS s2,
        1 AS t
);

See the details of the model in the `machine_learning_models` and `vector_autoregression_models` system catalog tables.

SQL

```
SELECT NAME,
    coefficients,
    coefficient_of_determination
FROM sys.machine_learning_models a,
    sys.vector_autoregression_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'var1';

name                                                coefficients
-------------------------------------------------------------------------------
var1                                                [-2.2737367544323206E-12, 0.89999999

Fetched 1 row
```

The model recovered the expected coefficients. The coefficient of determination is NULL here because the model did not enable metrics collection in the options.

This example checks that the model matches the data reasonably well.

SQL

```
SELECT var1({ { s1_lag1, s2_lag1 } }, { { s1_lag2, s2_lag2 } }) AS predicted,
    { { s1,
    s2 } } AS actual
FROM (
        SELECT s1,
            s2,
            s1_lag1,
            s2_lag1,
            s1_lag2,
            s2_lag2
        FROM (
                SELECT s1,
                    s2,
                    LAG(s1, 1) OVER(
                        ORDER BY t
                    ) AS s1_lag1,
                    LAG(s1, 2) OVER(
                        ORDER BY t
                    ) AS s1_lag2,
                    LAG(s2, 1) OVER(
                        ORDER BY t

# Classification Analysis

Use classification analysis techniques within Ocient with OcientML to categorize data, helping in decision-making and pattern identification.

Classification machine learning algorithms are available in OcientML™. There are many different popular classification algorithms, which work in slightly different ways with different strengths and weaknesses. These tutorials and examples cover some basic rules for using classification algorithms and how you can take advantage of these models in Ocient®.

It can be very challenging to anticipate which classification model is best suited for a data set. Often, it is best to experiment with multiple different models to see what happens.

## Logistic Regression

Despite its name, logistic regression is a classification algorithm, not a regression algorithm. Logistic regression is generally a good first step for trying out a classification model before moving on to more advanced options.

Logistic regression shares many restrictions with the support vector machines model. Both models require that all features are numeric. However, you can still use non-numeric data if you convert it using one-hot encoding. The class labels can be any data type.

> Use one-hot encoding to convert non-numeric data into numeric form.
>
> For example, if a feature is a color (such as red, green, or blue), then one-hot encoding can make three columns named `is_red`, `is_green`, and `is_blue`. For each row, set one color to the value `1` and the other colors to `0`.

This example uses the `lr_input` table, which represents the academic performance of students.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE TABLE mldemo.lr_input AS (
    SELECT hours_studied,
        grade_in_prev_course,
        CASE
            WHEN RAND() > (1.0 - effective_score) THEN true
            ELSE false
        END AS got_top_marks
    FROM
       ( SELECT hours_studied,
                grade_in_pr ev_course,
                (2 * grade_in_prev_course + hours_studied) / 10.0 AS effective_sc
            FROM
               ( SELECT mod(a.c1, 10) AS hours_studied,
                        mod(b.c1, 5) AS grade_in_prev_course
                    FROM sys.dummy100 a,
                        sys.dummy100 b
                )
        )
);
```

There are two features: the number of hours spent studying `hours_studied` and the grade in the previous course `grade_in_prev_course`. Both input features are numeric. There are also two classes: `true` and `false`. Class values do not need to be Boolean, and they can be any distinct values.

Students who have better grades in the previous course and spend more hours studying are more likely to have top marks in the course. However, this table also includes a randomness factor, which means that rows with the same features can have different classifications. This is normal in real-world data.

This example creates the logistic regression model on the table, including the `metrics` option. This option causes the model to calculate the percentage of samples that are correctly classified. The Ocient System puts this information into the system catalog tables.

SQL

```
CREATE MLMODEL lr1 TYPE LOGISTIC REGRESSION ON (
    SELECT *
    FROM mldemo.lr_input
) options('metrics'->'true');
```

This query selects the `machine_learning_models` and `logistic_regression_models` system catalog tables.

SQL

```
SELECT name,
    on_select,
    num_arguments,
    zero_case,
    one_case,
    correctly_classified
FROM sys.machine_learning_models a,
    sys.logistic_regression_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'lr1';

name                                                on_select
-------------------------------------------------------------------------------
lr1                                                 select * from mldemo.lr_input

Fetched 1 row
```

The model captures the two values for the two target classes. The `correctly_classified` column shows the model has almost 84 percent accuracy from working on the training data. This level of accuracy is pretty good, especially for a model using training data with significant randomness.

This model can predict which classification is most likely if you provide the number of hours studied and grades in the previous course.

First, review the average hours spent studying for each classification.

SQL

```
SELECT avg(hours_studied)
FROM mldemo.lr_input
WHERE got_top_marks;

(sum(hours_studied)) /(null_if(double(count(hours_studied)), (0)))
------------------------------------------------------------------
5.231264244536801

Fetched 1 row

SELECT avg(hours_studied)
FROM mldemo.lr_input
WHERE NOT got_top_marks;

(sum(hours_studied)) /(null_if(double(count(hours_studied)), (0)))
------------------------------------------------------------------
2.3534041715859897

Fetched 1 row
```

As expected, the rows where `got_top_marks` is true have a higher average value for `hours_studied`. The same should be true with `grade_in_prev_course`.

SQL

```
SELECT AVG(grade_in_prev_course)
FROM mldemo.lr_input
WHERE got_top_marks;

(SUM(grade_in_prev_course)) /(NULL_IF(DOUBLE(COUNT(grade_in_prev_course)), (0)))
--------------------------------------------------------------------------------
2.3535326451266925

Fetched 1 row

SELECT avg(grade_in_prev_course)
FROM mldemo.lr_input
WHERE NOT got_top_marks;

(sum(grade_in_prev_course)) /(NULL_IF(DOUBLE(COUNT(grade_in_prev_course)), (0)))
--------------------------------------------------------------------------------
0.9622195985832349

Fetched 1 row
```

You can also query to find the rows that are anomalies. In most cases, students achieved top marks in their class despite having minimal study hours and low grades in their previous classes.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT *
FROM mldemo.lr_input
WHERE got_top_marks != lr1(hours_studied, grade_in_prev_course)
LIMIT 10;

hours_studied       grade_in_prev_course got_top_marks
-------------------------------------------------------
1                   1                    true
1                   1                    true
1                   4                    false
1                   1                    true
1                   2                    true
1                   0                    true
1                   2                    true
1                   1                    true
1                   2                    true
1                   1                    true

Fetched 10 rows
```

For details about using this model type, see **Logistic Regression**.

## Support Vector Machine

Support vector machine (SVM) tries to find a hyperplane to divide data into two classes with these objectives:

- The hyperplane has the maximum margin, meaning the most distance between the two classes.
- The model correctly classifies the highest percentage of data points.

By default, SVM models in Ocient try to balance these two objectives. You can increase the priority of either objective by using the `regularizationCoefficient` option.

For data sets with two features, the SVM hyperplane represents a straight line on a Cartesian graph.

For three features, the hyperplane represents a plane.

This example uses the SVM model on the same classification data set of student performance as used in the logistic regression section.

SQL

```
CREATE MLMODEL svm1 TYPE SUPPORT VECTOR MACHINE ON (
    SELECT *
    FROM mldemo.lr_input
) options('metrics'->'true');

Modified 0 rows
```

The `machine_learning_models` and `support_vector_machine_models` system catalog tables for SVM contain almost the same information as logistic regression.

SQL

```
SELECT name,
    on_select,
    num_arguments,
    negative_case,
    positive_case,
    correctly_classified
FROM sys.machine_learning_models a,
    sys.support_vector_machine_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'svm1';
name                                          on_select
-------------------------------------------------------------------------------
svm1                                          select * from mldemo.lr_input

Fetched 1 row
```

The system catalog tables indicate the same percentage of correctly classified rows as the logistic regression model (about 84 percent).

The SVM model can increase the accuracy further by using a kernel. A kernel is a transformation to make data linearly separable. SVM in Ocient allows you to specify any kernel of your choice.

For example, suppose that a circle can separate two classes of data, dividing data points between those inside and outside the circle. The SVM model cannot find a line to divide the two classes very well, or this problem is not linearly separable. However, you can transform the data into three dimensions (three features) to make it linearly separable. This is the idea of a kernel.

You specify the kernel using the options `function1`, `function2`, `function3`, etc. Each function defines the formula for the kernel to create new features. Functions can use features from the original data set, represented by `x1`, `x2`, `x3`, etc.

To explain this, revisit the circle example. Suppose that the circle centered at the point `(2, 2)` is the class inside. Otherwise, the circle is the class outside. The data that is separable by a circle in two dimensions is linearly separable in three dimensions with the features `x1`, `x2`, `x1^2 + x2^2`.

This statement creates the data and the model.

© 2026 Ocient, Inc

SQL

```
CREATE TABLE mldemo.circle AS (
    SELECT x,
        y,
        CASE
            WHEN SQRT((x -2) ^ 2 + (y -2) ^ 2) <= 1 then 'INSIDE'
            ELSE 'OUTSIDE'
        END AS label
    FROM (
            SELECT RAND() * 10 as x,
                RAND() * 10 as y
            FROM sys.dummy10000
        )
);

Modified 10000 rows

CREATE MLMODEL svm2 type SUPPORT VECTOR MACHINE ON (
    SELECT x,
        y,
        label
    FROM mldemo.circle
) options(
    'metrics'->'true',
    'function1'->'x1',
    'function2'->'x2',
    'function3'->'x1^2 + x2^2'
);

Modified 0 rows
```

The example includes three functions, meaning that the kernel increases from two to three dimensions. The kernel functions refer to the original feature values `x1` and `x2`. If you examine the `correctly_classified` value in the `machine_learning_models` and `support_vector_machine_models` system catalog tables, you can see a model that classifies nearly everything correctly.

SQL

```
SELECT NAME,
    negative_case,
    positive_case,
    correctly_classified
FROM sys.machine_learning_models a,
    sys.support_vector_machine_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'svm2';
name                                                negative_case
-------------------------------------------------------------------------------
svm2                                                cast('OUTSIDE' as CHAR)

Fetched 1 row
```

One advantage of SVM kernels is that they are automatic. The model saves all the kernel information and transforms the data as needed. Hence, you can execute this model to predict a new point without redefining the kernel. You can pass in the two features the model was built over, and a prediction comes out.

> The **sys.machine_learning_model_options** table is the location where the SVM model saves kernel information.
>
> This table saves all the options that you specify. Some models also add additional keys to this dictionary to save certain information needed for when the model is executed.

SQL

```
SELECT svm2(2, 2);
COALESCE(('INSIDE'), (NULL));
--------------------------------------------
INSIDE

Fetched 1 row
```

For details about using this model type, see **Support Vector Machine**.

# Binary Classification with Neural Networks

A neural network using the `FEEDFORWARD NETWORK` model type can perform binary classification. To use this model for classification, you must either convert labels to either `0` and `1` (using the `log_loss` option) or convert labels to `-1` and `1` (using the `hinge_loss` option). Both options can achieve the same result.

This model can handle more complex cases, but using a different model for linearly separable data might be easier. In other words, a neural network model is useful when data is difficult to separate linearly using a kernel.

This example shows a feedforward network model using the `log_loss` option. Note the `CASE` statement to convert labels to `0` or `1`.

SQL

```
CREATE MLMODEL logloss TYPE FEEDFORWARD NETWORK ON (
    SELECT x,
        y,
        CASE
            WHEN label = 'INSIDE' THEN 0
            ELSE 1
        END AS target
    FROM mldemo.circle
) options(
    'metrics'->'true',
    'hiddenLayers'->'2',
    'hiddenLayerSize'->'2',
    'outputs'->'1',
    'lossFunction'->'log_loss'
);

Modified 0 rows
```

This query finds that the classification accuracy is about 97 percent.

SQL

```
SELECT COUNT(*) / 10000.0
FROM (
        SELECT x,
            y,
            label,
            CASE
                WHEN logloss(x, y) = 0 then 'INSIDE'
                ELSE 'OUTSIDE'
            END AS predicted
        FROM mldemo.circle
    )
WHERE label = predicted;

(_count(*)_0)/((10000.0))
--------------------------
0.9698

Fetched 1 row
```

To use the `hinge_loss` option, use `-1` and `1` in the `CASE` statement.

SQL

```
CREATE MLMODEL hingeloss TYPE FEEDFORWARD NETWORK ON (
    SELECT x,
        y,
        CASE
            WHEN label = 'INSIDE' THEN -1
            ELSE 1
        END AS target
    FROM mldemo.circle
) options(
    'metrics'->'true',
    'hiddenLayers'->'2',
    'hiddenLayerSize'->'2',
    'outputs'->'1',
    'lossFunction'->'hinge_loss'
);
Modified 0 rows
```

© 2026 Ocient, Inc

The accuracy of the `hinge_loss` version is exactly the same as the `log_loss` version.

SQL

```
SELECT count(*) / 10000.0
FROM (
        SELECT x,
            y,
            label,
            CASE
                WHEN hingeloss(x, y) = -1 THEN 'INSIDE'
                ELSE 'OUTSIDE'
            END AS predicted
        FROM mldemo.circle
    )
WHERE label = predicted;

(_count(*)_0)/((10000.0))
--------------------------
0.9698

Fetched 1 row
```

For details about using this model type, see **Feedforward Neural Network**.

## K-Nearest Neighbors

K-nearest neighbors (KNN) can only use numeric features, but KNN handles multi-classification in the Ocient System. This algorithm can handle an arbitrary number of target classes.

One drawback with KNN is that it does not work at training time other than to take a snapshot of the training data. The algorithm operates on the data when you execute the model, so it can be a slow model for large data sets.

To demonstrate KNN functionality, this example uses a similar circle of size (2, 2) with some modifications to use more classes:

- Data within a unit circle of (2, 2) is classified as `INSIDE`.

- Data within a radius of 2 is classified as `MIDDLE`.
- Any other data is classified as `OUTSIDE`.

SQL

```
CREATE TABLE mldemo.circles as (
    SELECT x, y,
        CASE
            WHEN SQRT((x -2) ^ 2 + (y -2) ^ 2) <= 1 THEN 'INSIDE'
            WHEN SQRT((x -2) ^ 2 + (y -2) ^ 2) <= 2 THEN 'MIDDLE'
            ELSE 'OUTSIDE'
        END AS label
    FROM (
            SELECT RAND() * 10 as x,
                RAND() * 10 as y
            FROM sys.dummy10000
        )
);

Modified 10000 rows
```

KNN works by finding the `k` nearest points to the one the model is trying to predict a classification for. `k` is an integer value that you must specify during model creation.

The model calculates distances using normal Euclidean distances. You can override the definition of distance by specifying a formula using the `distance` option.

After the model identifies the points, it computes a score for each class and returns the class with the highest score. The `weight` option can influence each score for the specified point. By default, the `weight` value is based on the inverse of the distance (`1.0/(d+0.1)`). In other words, a point closer to the point you are trying to predict has a larger influence on the output result than a point further away. Any point outside of the nearest `k` points has no influence.

This example uses three classes.

SQL

```
CREATE MLMODEL knn1 TYPE K NEAREST NEIGHBORS ON (
    SELECT x,
        y,
        label
    FROM mldemo.circles
) options('k'->'3');

Modified 0 rows
```

These queries test some values to see if the classifications are correct.

SQL

```
SELECT knn1(2, 2);

-------------------------------------------
INSIDE

Fetched 1 row

SELECT knn1(0.5, 2);

-------------------------------------------
MIDDLE

Fetched 1 row

SELECT knn1(5,5);

-------------------------------------------
OUTSIDE

Fetched 1 row
```

KNN models perform work when you execute the model, and the amount of work increases as the input data increases.

One solution to this is data reduction, which means finding a smaller subset of rows to build the KNN model over, enough to ensure that the accuracy of the model is still high. This method front-loads the work when you create the model so that it is much faster to execute on new data.

To use the data reduction feature, set the `dataReduction` option to `true`. By default, the execution stops when the database finds a model that is 90 percent accurate over the training data or when the reduced model increases to 1,000 rows of data. You can override these defaults by setting the `maxReducedRows` or `targetAccuracy` options.

Additionally, if you are using data reduction, you can ask the database to collect metrics on the percent of rows correctly classified by the model because this is much faster to do on the reduced data set.

This example builds another KNN model over the same data and uses data reduction to find a model that is at least 95 percent accurate.

SQL

```
CREATE MLMODEL knn2 TYPE K NEAREST NEIGHBORS ON (
    SELECT x,
        y,
        label
    FROM mldemo.circles
) options(
    'k'->'3',
    'dataReduction'->'true',
    'metrics'->'true',
    'targetAccuracy'->'0.95'
);

Modified 0 rows
```

Query the `machine_learning_models` and `k_nearest_neighbor_models` system catalog tables to see the snapshot table used for the model and its accuracy.

SQL

```
SELECT table_name,
    correctly_classified
FROM sys.machine_learning_models a,
    sys.k_nearest_neighbor_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'knn2';

table_name                                    correctly_classified
--------------------------------------------------------------------
temp.knn86947930347148676                     0.9541

Fetched 1 row
```

The model with data reduction correctly classifies about 95 percent of the training data. To see the size of the KNN model snapshot, you can query it by its table name.

SQL

```
SELECT COUNT(*) FROM temp.knn86947930347148676;

count(*)
--------------------
300

Fetched 1 row
```

The snapshot is only 300 rows. Without data reduction, the row count would be much larger by orders of magnitude.

For details about using this model type, see **K Nearest Neighbor Classification**.

## Multi-Class Classification with Neural Networks

The `FEEDFORWARD NETWORK` model type can also perform multi-class classification when the feature classes are numeric. Multi-class classification works by using vectors, where each position in the vector indicates the score for that class. The **argmax** value of the score of each vector returns the class index.

Much of this example is similar to the previous **Binary Classification with Neural Networks** tutorial, with these modifications to the model options:

- Set the `lossFunction` option to `cross_entropy`.
- Set the `outputs` option to specify the number of classes for the model to use (in this example: `3`).
- Set the `useSoftMax` option to `true`, which applies a **softmax** function to the final vector.

> When the loss function is `cross_entropy_loss`, the option `useSoftMax` defaults to `true`.

SQL

```
CREATE MLMODEL crossentropy TYPE FEEDFORWARD NETWORK ON (
    SELECT x,
        y,
        CASE
            WHEN label = 'INSIDE' THEN { { 1.0,
            0.0,
            0.0 } }
            WHEN label = 'MIDDLE' THEN { { 0.0,
            1.0,
            0.0 } }
            ELSE { { 0.0,
            0.0,
            1.0 } }
        END AS TARGET
    FROM mldemo.circles
) options(
    'metrics'->'true',
    'hiddenLayers'->'2',
    'hiddenLayerSize'->'2',
    'outputs'->'3',
    'lossFunction'->'cross_entropy_loss',
    'useSoftMax'->'true'
);

Modified 0 rows
```

Execute this model to return a vector.

```
SQL

SELECT crossentropy(5,5) AS predicted;

predicted
--------------------------------------------------------------------------------
[[1.3436428911280516E-7, 1.811726873154417E-7, 0.99999968446302 36]]

Fetched 1 row
```

To get the classification, use the `VECTOR_ARGMAX` function to retrieve the index of the largest value. This function returns the 1-based index of the largest value in the vector.

```
SQL

SELECT VECTOR_ARGMAX(crossentropy(5,5)) AS predicted;

predicted
--------------------
3

Fetched 1 row
```

This query finds the overall accuracy of the model.

© 2026 Ocient, Inc

SQL

```
SELECT count(*) / 10000.0
FROM mldemo.circles
WHERE (
        label = 'INSIDE'
        AND VECTOR_ARGMAX(crossentropy(x, y)) = 1
    )
    OR (
        label = 'MIDDLE'
        AND VECTOR_ARGMAX(crossentropy(x, y)) = 2
    )
    OR (
        label = 'OUTSIDE'
        AND VECTOR_ARGMAX(crossentropy(x, y)) = 3
    );

(_count(*)_0)/((10000.0))
--------------------------
0.9298

Fetched 1 row
```

The model is about 93 percent effective. You can improve the accuracy by modifying the **Model Options**, including:

- `hiddenLayers`
- `hiddenLayerSize`
- `lossFuncNumSamples`

Increasing the resources of these options can improve accuracy, but could increase the time needed to train the model.

For details about using this model type, see **Feedforward Neural Network**.

## Multi-Class Classification with Support Vector Machines and Logistic Regression

Both logistic regression and SVM are binary classifiers, but you can use either to build a multi-class classifier to handle any number of classes. OcientML can perform this automatically with either model.

This example shows the `CREATE` statement for the SVM model, which uses the same data as the **K Nearest Neighbors** and **Multi-Class Classification with Neural Networks** examples.

SQL

```
CREATE MLMODEL circ1 TYPE SUPPORT VECTOR MACHINE ON (
    SELECT x,
        y,
        label
    FROM mldemo.circles
) options(
    'metrics'->'true',
    'function1'->'x1',
    'function2'->'x2',
    'function3'->'x1^2 + x2^2'
);

Modified 0 rows
```

This statement uses the same kernel as the example for performing binary classification on **Support Vector Machines**.

This query checks the metrics in the `machine_learning_models` and `support_vector_machine_models` system catalog tables to see the accuracy.

SQL

```
SELECT correctly_classified
FROM sys.machine_learning_models a,
    sys.support_vector_machine_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'circ1';

correctly_classified
---------------------
0.9579

Fetched 1 row
```

This model is slightly more accurate than the neural network classifier.

This example tries logistic regression.

SQL

```
CREATE mlmodel circ2 TYPE LOGISTIC REGRESSION ON (
    SELECT x,
        y,
        label
    FROM mldemo.circles
) options('metrics'->'true');

Modified 0 rows

SELECT correctly_classified
FROM sys.machine_learning_models a,
    sys.logistic_regression_models b
WHERE a.id = b.machine_learning_model_id
    AND NAME = 'circ2';

correctly_classified
---------------------
0.9028

Fetched 1 row
```

Logistic regression shows lower accuracy than the neural network model.

These classification models can handle non-numeric data.

## Naive Bayes

The first of these models is naive Bayes. This model can handle binary or multi-class classification and features of any data type.

By default, naive Bayes treats each feature as a discrete value. For example, if you assign features with values of `1`, `2`, `3`, and `4`, the model does not give any numeric significance to them. In this case, this model cannot predict the class for the sample with a feature value of `3.5` because that value is not explicitly assigned as a feature.

However, the naive Bayes model can define certain input features as continuous features. These should be numeric values. In this case, the naive Bayes model finds the best-fit normal distribution for that feature to do the probability calculations.

Naive Bayes models essentially use the probability rules of Bayes' Theorem to compute the most likely class based on the training data. The rules are only correct if the features are independent (uncorrelated). However, in practice, the models tend to work well with real-world data.

This example uses this simple table to demonstrate naive Bayes models.

Ocient Proprietary and Confidential

SQL

```
SELECT * FROM mldemo.cars;

color                                                type
---------------------------------------------------------------------------------
yellow                                               sports
yellow                                               sports
yellow                                               suv
red                                                  sports
yellow                                               suv
red                                                  suv
red                                                  sports
yellow                                               suv
red                                                  sports
red                                                  sports

Fetched 10 rows
```

`color`, `type`, and `origin` are the input features, which are all strings. `true` and `false` are the class labels. In this case, all of the input features are discrete.

This example builds the naive Bayes model.

SQL

```
CREATE MLMODEL nb1 TYPE NAIVE BAYES ON (
    SELECT color,
        type,
        origin,
        stolen
    FROM mldemo.cars
) options('metrics'->'true');

Modified 0 rows
```

This query examines the information in the `machine_learning_models` and `naive_bayes_models` system catalog tables for naive Bayes models.

SQL

```
SELECT NAME,
    on_select,
    num_arguments,
    result_probability_table,
    feature_result_matrix_table,
    correctly_classified
FROM sys.machine_learning_models a,
    sys.naive_bayes_models b
WHERE a.id = b.machine_le arning_model_id
    AND NAME = 'nb1';

name                                                on_select
-------------------------------------------------------------------------------
nb1                                                 select color, "type", origin, stolen

Fetched 1 row
```

In the model, the `correctly_classified` value indicates the accuracy is 80 percent, meaning just two rows are classified incorrectly. The two table names in the `temp` schema hold all the necessary data for executing the model as a function.

This query calls the model to classify new data.

SQL

```
SELECT nb1('red', 'suv', 'domestic') AS prediction;

prediction
-----------
false

Fetched 1 row
```

Here is another example with a different data set to show how continuous features work with naive Bayes models.

SQL

```
SELECT * FROM mldemo.golf;

humidity            play
-------------------------
70                  false
75                  true
86                  true
95                  false
80                  true
85                  false
96                  true
90                  true
91                  false
90                  false
70                  true
70                  true
80                  true
65                  true

Fetched 14 rows
```

In this case, the only input feature is a continuous feature, but you can have multiple continuous features, and you can have a mix of continuous and discrete features.

To build a naive Bayes model over this data, you must set which input features are continuous in the model.

SQL

```
CREATE MLMODEL nb2 TYPE NAIVE BAYES ON (
    SELECT *
    FROM mldemo.golf
) options('continuousFeatures'->'1', 'metrics'->'true');

Modified 0 rows
```

The `continuousFeatures` option is a comma-separated list (no spaces) of input column indexes that are continuous. Indexes start at 1.

This query checks the `correctly_classified` value in the `machine_learning_models` and `naive_bayes_models` system catalog tables.

SQL

```
SELECT correctly_classified
FROM sys.machine_learning_models a,
    sys.naive_bayes_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'nb2';

correctly_classified
--------------------
0.7142857142857143

Fetched 1 row
```

Naive Bayes is a powerful classification algorithm, but it operates as a black box, making it hard to assess how it makes classification decisions.

For details, see **Naive Bayes Classification**.

## Decision Trees

Unlike naive Bayes, the decision tree model allows you to see how the model works and makes its decisions.

A decision tree branches based on the value of a single feature, while the leaves of the tree are the output classes. For SQL syntax, this model uses multiple nested `CASE` statements. You can examine the whole nested `CASE` statement that defines the model, but it might be very long.

The decision tree model in Ocient has limited support for continuous features. The model finds the average value of the feature and allows a two-way branch based on whether the value is lower or higher than the average.

Creating a decision tree model is exactly like a naive Bayes model, except with a different type. Decision trees also use the `continuousFeatures` option, which works the same way.

These decision tree examples use the same data sets as the naive Bayes examples.

SQL

```
CREATE MLMODEL dt1 TYPE DECISION TREE ON (
    SELECT color,
        "type",
        origin,
        stolen
    FROM mldemo.cars
) options('metrics'->'true');

Modified 0 rows
```

This query examines the `machine_learning_models` and `decision_tree_models` system catalog tables.

SQL

```
SELECT correctly_classified
FROM sys.machine_learning_models a,
    sys.decision_tree_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'dt1';

correctly_classified
----------------------
0.8

Fetched 1 row
```

This model has the same 80 percent accuracy as the naive Bayes model.

This query examines the `CASE` statement that defines the model.

SQL

```
SELECT case_statement
FROM sys.machine_learning_models a,
    sys.decision_tree_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'dt1';

case_statement
-------------------------------------------
CASE
    WHEN x3 = cast('domestic' as CHAR) THEN CASE
        WHEN x1 = cast('red' as CHAR) THEN CASE
            WHEN x2 = cast('sports' as CHAR) THEN cast('true' as BOOLEAN)
            ELSE cast('false' as BOOLEAN)
        END
        WHEN x1 = cast('yellow' as CHAR) THEN cast('false' as BOOLEAN)
        ELSE cast('false' as BOOLEAN)
    END
    WHEN x3 = cast('imported' as CHAR) THEN CASE
        WHEN x2 = cast('suv' as CHAR) THEN CASE
            WHEN x1 = cast('red' as CHAR) THEN cast('false' as BOOLEAN)
            WHEN x1 = cast('yellow' as CHAR) THEN cast('true' as BOOLEAN)
            ELSE cast('false' as BOOLEAN)
        END
        WHEN x2 = cast('sports' as CHAR) THEN cast('true' as BOOLEAN)
        ELSE cast('false' as BOOLEAN)
    END
    ELSE cast('false' as BOOLEAN)
END

Fetched 1 row
```

Like with the naive Bayes model, the decision tree model can predict new data.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT dt1('red', 'suv', 'domestic') AS prediction;

prediction
-----------
false

Fetched 1 row
```

This example builds a model over the golfing data.

SQL

```
CREATE mlmodel dt2 TYPE DECISION TREE ON (
    SELECT *
    FROM mldemo.golf
) options('continuousFeatures'->'1', 'metrics'->'true');

Modified 0 rows
```

Review the `machine_learning_models` and `decision_tree_models` system catalog tables to see the accuracy of this model.

SQL

```
SELECT correctly_classified
FROM sys.machine_learning_models a,
    sys.decision_tree_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'dt2';

correctly_classified
----------------------
0.7142857142857143

Fetched 1 row
```

Again, the decision tree shows similar accuracy to the naive Bayes model.

# Clustering Analysis and Dimensionality Reduction

Apply clustering and dimensionality reduction in Ocient with OcientML using k-means, PCA, and related algorithms for unsupervised exploration of data.

This tutorial uses examples to explain the clustering and dimensionality reduction capabilities in OcientML™.

## Clustering Models

Clustering models bear similarities to classification, but they use unsupervised learning, which means they do not use any class labels. Instead, the algorithm tries to identify groupings on its own by finding clusters of data that seem closer to each other and farther away from other clusters.

These models generate an integer label, but its ordering is arbitrary. The Ocient® clustering models require you to specify upfront the number of clusters.

### K-Means Clustering

K-means is by far the most well-known clustering algorithm because it is simple and fast. K-means performs particularly well if you can scale your features so clusters are roughly circular and equal in size.

These examples demonstrate the k-means model. The examples do not use a data set that is primed for optimal performance of the model, such that they show the shortcomings of the k-means model and how it can perform relatively well even with sub-optimal data.

The examples use a data set of three-dimensional points.

Fetched 10 rows
```

This example shows a k-means model created over this data. You can specify multiple options, but the only one that is required is the `k` value, which represents the number of clusters.

SQL

```
CREATE MLMODEL kmeans1 TYPE KMEANS ON (
    SELECT x,
        y,
        z
    FROM mldemo.clusters_3d
) options('k'->'3');

Modified 0 rows
```

This data set has labels, but they are hidden from the model to allow for unsupervised learning.

These example queries compare how well the unsupervised k-means clustering performs against the actual correct classes and labels.

Before you can do that, you must figure out which cluster numbers correspond to which labels.

SQL

```
SELECT COUNT(*),
    cluster_num
FROM (
        SELECT kmeans1(x, y, z) AS cluster_num
        FROM mldemo.clusters_3d
        WHERE label = 'LEFT'
    )
GROUP BY cluster_num;

count(*)            cluster_num
--------------------------------
3165                0
146329              1

Fetched 2 rows

SELECT COUNT(*),
    cluster_num
FROM (
        SELECT kmeans1(x, y, z) AS cluster_num
        FROM mldemo.clusters_3d
        WHERE label = 'RIGHT'
    )
GROUP BY cluster_num;

count(*)            cluster_num
--------------------------------
3877                0
145761              2

Fetched 2 rows

SELECT COUNT(*),
    cluster_num
FROM (
        SELECT kmeans1(x, y, z) AS cluster_num
        FROM mldemo.clusters_3d
        WHERE label = 'CENTER'
    )
GROUP BY cluster_num;
```

```
count(*)            cluster_num
-------------------------------
700868              0

Fetched 1 row
```

The results indicate that cluster `0` is the `CENTER` class, cluster `1` is `LEFT`, and cluster `2` is `RIGHT`.

With that information, you can compute the overall accuracy.

SQL

```
SELECT count(*) / 1000000.0
FROM mldemo.clusters_3d
WHERE (
        kmeans1(x, y, z) = 0
        AND label = 'CENTER'
    )
    OR (
        kmeans1(x, y, z) = 1
        AND label = 'LEFT'
    )
    OR (
        kmeans1(x, y, z) = 2
        AND label = 'RIGHT'
    );

(_count(*)_0)/((1000000.0))
---------------------------
0.992958

Fetched 1 row
```

The accuracy is very good. This calculation indicates that the model never miscategorized `CENTER`, but there were some wrong classifications for the `LEFT` and `RIGHT` labels, although they were rare.

For details, see **K-Means Clustering**.

## Gaussian Mixture Models

Gaussian mixture models (GMMs) also perform clustering, however they use a significantly more complex algorithm. GMMs can handle several things that k-means cannot, such as:

- GMMs can handle clusters that are not circular, i.e., they have different variances in different directions.
- GMMs can handle clusters that have an arbitrary rotation, i.e., they can have covariances.
- GMMs can handle the fact that all clusters might not be equally as likely, i.e. if a point is located right between two clusters, then it is more likely to be the one more common in the training data.
- GMMs can show the probability of a new point belonging to each cluster rather than outputting a single cluster value.

GMMs operate by finding a weighted mixture of k multi-variate Gaussians that is most likely to represent the population from which the data was sampled. Each Gaussian in the mix has a mean vector, which represents the center of each cluster.

After you create the model, it is simple to determine the cluster that a point most likely belongs to. The examples demonstrate how to find the highest probability cluster.

This example makes a model over the same data set. This model requires the `numDistributions` option, which represents the number of clusters.

SQL

```
CREATE MLMODEL gmm TYPE GAUSSIAN MIXTURE MODEL ON (
    SELECT x,
        y,
        z
    FROM mldemo.clusters_3d
) options('metrics'->'true', 'numDistributions'->'3');

Modified 0 rows
```

This query executes the GMM model.

```
SQL

SELECT gmm(0,0,0) AS class_probabilities;

class_probabilities
-------------------------------------------------------------------------------
[[2.0445296213545875E-4, 0.999582295498657, 2.1325153920763012E-4]]

Fetched 1 row
```

The results are very different than executing a k-means model because these are probabilities. In this case, the output means the probability of `(0,0,0)` being the second class is very high (greater than 99.9 percent), while the probability of it being the other classes is essentially zero.

To find the most likely class, use the `VECTOR_ARGMAX` function, which returns a 1-based class index.

```
SQL

SELECT VECTOR_ARGMAX(gmm(0,0,0)) AS class_probabilities;

class_probabilities
--------------------
1

Fetched 1 row
```

You can write a query to assess the accuracy of this model. But first, you must figure out the association between classes and labels.

SQL

```
SELECT COUNT(*),
    cluster_num
FROM (
        SELECT VECTOR_ARGMAX(gmm(x, y, z)) AS cluster_num
        FROM mldemo.clusters_3d
        WHERE label = 'LEFT'
    )
GROUP BY cluster_num;

count(*)            cluster_num
----------------------------------------

```

This model misclassified 20 rows, which is far better than the 7,042 rows the k-means model misclassified. This is a direct result of the additional complexity of the GMM.

GMM models can handle much more complex situations than k-means models, but this comes at the cost of more time training and executing the model. The time a GMM model takes compared to a k-means model depends on the number of clusters.

For details, see **Gaussian Mixture**.

# Dimensionality Reduction

Dimensionality reduction algorithms reduce the number of input features while still keeping as much of the meaningful properties of the data as possible. Models are quicker to build, and often higher quality after a dimensionality reduction model reduces the number of input features.

A common first step in an analysis is to use dimensionality reduction to simplify the data. See these examples that demonstrate how to use dimensionality reduction as a preprocessing step before using other model types.

## Principal Component Analysis

Principal component analysis (PCA) is an unsupervised algorithm that only operates on the inputs, and does not understand what the data is being used for. It is also a linear dimensionality reduction algorithm, meaning that the new features it generates are linear combinations of existing features.

PCA generates as many new features as there are input features. So by itself, it is not reducing the number of dimensions. However, PCA creates new features that try to maximize variance and sorts the new features in terms of the amount of variance they

contain. The system catalog tables provide information on how much variance is contained by the new features. You can use this information to find how many trailing new features to drop.

This PCA tutorial uses a new data set. Start with a regression problem that is trying to find the best-fit polynomial for `f(x1, x2, x3) = y`. The tutorial starts with a **Polynomial Regression** model to see how well it does using three input features, and then it uses PCA to reduce the number of variables without losing accuracy.

This example shows the Polynomial Regression model.

SQL

```
CREATE MLMODEL poly TYPE POLYNOMIAL REGRESSION ON (
    SELECT x1,
        x2,
        x3,
        y
    FROM mldemo.pca_poly
) options('order'->'2', 'metrics'->'true');

Modified 0 rows
```

The system catalog table shows that the model fits the data perfectly.

SQL

```
SELECT coefficient_of_determination
FROM sys.machine_learning_models a,
    sys.polynomial_regression_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'poly';

coefficient_of_determination
----------------------------
1.0

Fetched 1 row
```

In this instance, PCA can reduce the three independent variables to two.

The first step is to build a PCA model over the input features.

SQL

```
CREATE MLMODEL pca1 TYPE PRINCIPAL COMPONENT ANALYSIS ON (
    SELECT x1,
        x2,
        x3
    FROM mldemo.pca_poly
);

Modified 0 rows
```

The model does not include `y` because PCA operates over only the input features.

Examine the `machine_learning_models` and `principal_component_analysis_models` system catalog tables.

SQL

```
SELECT importance
FROM sys.machine_learning_models a,
    sys.principal_component_analysis_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'pca1';

importance
-------------------------------------------------------------------------------
[0.6022962127628679, 0.33286202821081917, 0.06484175902631285]

Fetched 1 row
```

The `importance` value indicates that over 93 percent of the signal is in the first two PCA output features, which means it is possible to have a robust model even if you remove the third feature.

This example uses the Polynomial Regression model to access the PCA output features. The example executes the `pca1` PCA function with the PCA input features followed by

the number of features. This number starts at `1`, so this example uses PCA features `1` and `2`, but not the last feature.

SQL

```
CREATE MLMODEL poly2 TYPE POLYNOMIAL REGRESSION ON (
    SELECT pca1(x1, x2, x3, 1),
        pca1(x1, x2, x3, 2),
        y
    FROM mldemo.pca_poly
) options('order'->'2', 'metrics'->'true');

Modified 0 rows
```

Notice that the example still references all three input features, but this model now has only two independent variables. As a result, the model trains 15 percent faster than the version with three independent variables. It is also a much simpler model. The model has six terms in the polynomial regression instead of 10, when there were three independent variables.

This query examines how well the model fits the data.

SQL

```
SELECT coefficient_of_determination
FROM sys.machine_learning_models a,
    sys.polynomial_regression_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'poly2';

coefficient_of_determination
----------------------------
0.9952839146818417

Fetched 1 row
```

The model is a great fit with more than 99 percent accuracy.

In contrast, here is an example where PCA is not a good idea. This example goes back to the three-dimensional clusters data set used in the **Clustering Models** examples.

This example creates the PCA model and checks the `importance` value of the PCA output features in the `machine_learning_models` and `principal_component_analysis_models` system catalog tables.

SQL

```
CREATE MLMODEL pca2 TYPE PRINCIPAL COMPONENT ANALYSIS ON (
    SELECT x,
        y,
        z
    FROM mldemo.clusters_3d
);

Modified 0 rows

SELECT importance
FROM sys.machine_learning_models a,
    sys.principal_component_analysis_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'pca2';

importance
--------------------------------------------------------------------------------
[0.3688781607553818, 0.3333390832624229, 0.2977827559821952]

Fetched 1 row
```

In this case, all three PCA output features are fairly evenly weighted. By removing the last feature, the model covers only about 70% of the signal. This strongly indicates that proceeding with a two-feature model would be problematic and inaccurate.

## Linear Discriminant Analysis

While PCA is unsupervised, linear discriminant analysis (LDA) is a supervised dimensionality reduction algorithm. LDA works only with numeric classification algorithms, but the classification can be binary or multi-class. Hence, LDA understands how the data should be used, making it operate differently.

Creating an LDA model is mostly similar to PCA. One difference is that LDA also requires a class or label.

This tutorial uses the three-dimensional cluster data that the PCA model struggled to work with. The example uses LDA to reduce the features of the cluster data by using the label already contained in the data set.

SQL

```
CREATE MLMODEL lda1 TYPE LINEAR DISCRIMINANT ANALYSIS ON (
    SELECT x,
        y,
        z,
        label
    FROM mldemo.clusters_3d
);

Modified 0 rows
```

As with PCA, there is an `importance` column in the system catalog tables.

SQL

```
SELECT importance
FROM sys.machine_learning_models a,
    sys.linear_discriminant_analysis_models b
WHERE a.id = b.machine_learning_model_id
    AND name = 'lda1';

importance
--------------------------------------------------------------------------------
[1.0000000000000133, -1.4051695910079908E-20, -1.3342566035320652E-14]

Fetched 1 row
```

This output strongly indicates that only the first LDA output feature matters, which means that it is possible to make a single feature classification model.

This example takes the LDA-reduced model as input and uses it to create a neural network model, using the `FEEDFORWARD NETWORK` model. Note that this model uses the `cross_entropy_loss` option to enable multi-class classification.

SQL

```
CREATE MLMODEL three_d_clusters_with_1_feature TYPE FEEDFORWARD NETWORK ON (
    SELECT lda1(x, y, z, 1),
        CASE
            WHEN label = 'LEFT' THEN { { 1.0,
            0.0,
            0.0 } }
            WHEN label = 'RIGHT' THEN { { 0.0,
            1.0,
            0.0 } }
            ELSE { { 0.0,
            0.0,
            1.0 } }
        END AS target
    FROM mldemo.clusters_3d
) options(
    'metrics'->'true',
    'hiddenLayers'->'2',
    'hiddenLayerSize'->'4',
    'outputs'->'3',
    'lossFunction'->'cross_entropy_loss',
    'useSoftMax'->'true'
);

Modified 0 rows
```

Execute the model for a new point to see if it returns a reasonable value.

```SQL
SELECT three_d_clusters_with_1_feature(lda1(0, 0, 0, 1)) AS predicted;

predicted
-------------------------------------------------------------------------------
[[0.007386760165583984, 0.0022085315302674473, 0.9904047083041486]]

Fetched 1 row
```

In this case, the query asks for a prediction for the input `0, 0, 0`. This input first passes through the LDA model because that is what the neural network model was built on.

The query asks the LDA model for its first component, and then runs the neural network on that value. The neural network outputs a vector of class probabilities; `VECTOR_ARGMAX` returns the 1-based index of the highest probability.

In this example, the highest probability class is the third class, which the query defines as `CENTER`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT count(*) / 1000000.0
FROM mldemo.clusters_3d
WHERE (
        VECTOR_ARGMAX(
            three_d_clusters_with_1_feature(lda1(x, y, z, 1))
        ) = 1
        AND label = 'LEFT'
    )
    OR (
        VECTOR_ARGMAX(
            three_d_clusters_with_1_feature(lda 1(x, y, z, 1))
        ) = 2
        AND label = 'RIGHT'
    )
    OR (
        VECTOR_ARGMAX(
            three_d_clusters_with_1_feature(lda1(x, y, z, 1))
        ) = 3
        AND label = 'CENTER'
    );

(_count(*)_0)/((1000000.0))
----------------------------
0.818108

Fetched 1 row
```

This model is nearly 82 percent accurate despite being simplified from three features to one. While the accuracy is worse, the time required to train this model is greatly reduced.

# Transactions

Learn how the OcientAIQ Unified Data Platform supports transactions in Ocient SQL and in the JDBC and pyocient drivers, including the supported SQL statements.

The Ocient® System supports transactions. A transaction groups one or more SQL statements into a single unit of work that the database either commits as a whole or discards as a whole. Transactions let you apply a set of related changes together and roll them back if any statement fails.

The following SQL statements are supported in transactions.

- **COMMIT**
- **CREATE TABLE AS SELECT**
- **CREATE TRANSACTIONAL PIPELINE**
- **INSERT**
- **QUIESCE PIPELINE**
- **ROLLBACK**
- **SELECT**
- **SET AUTOCOMMIT**
- **START PIPELINE**
- **STOP PIPELINE**
- **WITH**

If you execute a SQL statement that a transaction does not support, the database throws an error.

## Transaction Support in Ocient SQL

By default, a connection uses autocommit mode, in which the database commits each SQL statement immediately. To group several statements into a single transaction, disable autocommit with the **SET AUTOCOMMIT** statement. After you disable

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

autocommit, the database adds each subsequent statement to the current transaction until you end it.

To end a transaction, execute the **COMMIT** statement to permanently save all changes made since the transaction started. To discard those changes instead, execute the **ROLLBACK** statement. For the syntax and examples of these statements, see the **Transactional Control Language (TCL) Statement Reference**.

## Transaction Support in the Drivers

The Ocient JDBC driver supports transactions. You can disable autocommit and execute the COMMIT and ROLLBACK commands from the Ocient JDBC CLI program. For details, see **Commands Supported by the Ocient JDBC CLI Program**.

The pyocient module also supports transactions. You can set the autocommit attribute and call the commit and rollback methods on a connection object. For details, see **Ocient Python Module (pyocient)**.

# Ocient Security Guide

Enhance Ocient System security with best practices for authentication, network security, encryption, access control, auditing, and regulatory compliance. This page lists ports and protocols needed for internal and external communication.

This security guide is intended to assist organizations in hardening Software as a Service (SaaS) or customer-deployed Ocient® Systems. OcientCloud® and Ocient Management Services include Ocient support personnel configuring these settings based on organizational requirements and the applicable service agreement. Implement these security features and measures to protect an Ocient System and ensure data privacy.

This guide is not exhaustive and represents a security baseline for an Ocient System. Depending on your environment architecture and services, not all security features and measures might apply.

## Authentication and Access Control

This section applies to the database application of the Ocient System. You can install the database application on a standard Linux® operating system (OS) distribution and apply authentication and access controls to the application host.

### Identity Provider or Single Sign-On (SSO)

You can configure the OcientAIQ™ Unified Data Platform to use any OpenID Connect (OIDC) identity provider (such as OKTA®) for SSO. For details, see **Authentication Methods**.

Due to the potential sensitive data access provided through the Ocient System, use multi-factor authentication (MFA) for all accounts that access the Ocient System.

Ocient recommends implementing an OIDC identity provider on the Ocient System and utilizing MFA for authentication access. Any local accounts should be limited to emergency access to recover SSO issues.

### Role-Based Access Control (RBAC) Groups

© 2026 Ocient, Inc

The Ocient System includes default System and Database Roles. The system also allows database administrators to create access groups with specific tables or views. You can assign these access groups to database users to restrict access to data based on the data type or classification.

Ocient recommends assigning System and Database Roles based on the principles of least privilege, separation of duties, and need-to-know. Access groups with specific tables, rows, or views can further restrict access based on data security requirements.

For details, see **Manage Users, Groups, and Roles**.

# Network Security

This section applies to the network segment that hosts the Ocient System.

## Secure Bucket Access and Data Streaming

The Ocient System supports data loading using the Apache® Kafka® stream, cloud bucket (e.g., Amazon® Web Services℠ (AWS℠) S3), or local file source. For details, see **SOURCE Options**.

### Secure Bucket Access

If loading data from a cloud bucket like AWS S3, Google® Cloud™ GCP storage bucket, and so on, use network access controls, IP whitelisting, or data-in-transit encryption between the Loader Nodes in the Ocient System and the cloud bucket. Only Loader Nodes need access to a data source.

### Secure Data Streaming

The Ocient System supports Kafka Source data streaming to Loader Nodes: `source-configuration`

Ocient recommends utilizing data-in-transit encryption between the Kafka data source and Loader Nodes.

## Network Exposure and Firewall

The Ocient System hosts should remain in the same network segment. However, you must apply host and network-based firewalls.

Ocient recommends using deny-all allow-by-exception firewall policies on hosts and network infrastructure to secure Ocient System environments.

> The hosts in the Ocient System should not be publicly accessible but within organizational network boundaries and security (or communication service provider (CSP) network boundaries and security).

The Ocient System uses these ports, protocols, and services externally and internally.

### Communications External to the Ocient System

| Port | Protocol | Service | Source | Destination |
|---|---|---|---|---|
| 4050 | TCP | JDBC | JDBC Connectors | Ocient SQL Hosts |
| 8080 | TCP | LAT | LAT Client | Ocient Loader Ho |
| 8090 | TCP | Extractor Engine | Metrics Platform | Ocient Loader Ho |
| 9090 | TCP | rolehostd | Metrics Platform | Ocient Loader Ho |

### Communications Internal to the Ocient System

| Port | Protocol | Service | Source | Destination |
|---|---|---|---|---|
| 5050 | TCP | rolehostd | Ocient LAT Hosts | Ocient Loader Ho |
| 17600 | TCP | rolehostd | Ocient SQL and Metadata Hosts | Ocient SQL and Metadata Hosts |
| 17700 | TCP | rolehostd | Ocient SQL, Loader, and Foundation Hosts | Ocient SQL, Loac and Foundation Hosts |
| 17800 | TCP | rolehostd | Ocient Loader and Foundation Hosts | Ocient Loader ar Foundation Hosts |
| 17900 | TCP | rolehostd | Ocient SQL, Metadata, Loader, and Foundation Hosts | Ocient SQL, Metadata, Loade and Foundation Hosts |

# Data Security and Encryption

This section covers the data security and encryption of the database application. Apply the data security and encryption controls to the Linux OS host.

### Data-at-Rest Encryption

The Ocient System supports self-encryption drives (SED) that meet the Trusted Computing Group (TCG) Opal standard or better.

Ocient recommends utilizing NVMe drives that support Opal or SED and implementing data-at-rest encryption. Encryption strength should be based on data and system sensitivity. For details, see **Server Hardware Requirements** and **Data Drive Requirements**.

### Data-in-Transit Encryption

You can encrypt external connections using JDBC through transport layer security (TLS) or secure sockets layer (SSL). For details, see **Secure Connections Using TLS**.

Ocient recommends using at least TLS 1.2 for external connections to the Ocient System.

## System and Application Security

This section applies to both the Linux OS host and the database application.

### Operating System Hardening

For operating systems supported by the Ocient System, see **Ocient System Requirements**.

Ocient recommends the use of an industry-standard OS hardening baseline like the CIS Benchmarks™ or the Defense Information Systems Agency (DISA) Security Technical Implementation Guides (STIGs).

### Operating System Patching

You must frequently and consistently update hosts running the Ocient System to remediate any existing vulnerabilities within the OS.

Ocient recommends performing periodic vulnerability assessments or scans and updating OS packages based on severity and timeframe.

### Application Patching

Ocient tracks, monitors, and remediates vulnerabilities within the Ocient System application and publishes updated software releases periodically.

Ocient recommends keeping your Ocient System application updated to the most current version.

For details, see **Ocient Software Upgrade**.

### Application and System Maintenance

Ocient recommends performing regular and periodic application and system maintenance to preserve system performance. For details about the Ocient System maintenance activities, see **Maintenance Overview**.

## Secrets and Key Management

This section applies to secrets and keys within the Ocient System and database application. The section does not include Linux OS host secrets and keys but should have appropriate authentication and access controls applied. For details, see **Set Up Data Encryption**.

### SED Key

Ocient recommends using a Key Management Interoperability Protocol (KMIP) compliant key management platform to handle SED lock and unlock operations.

By default, during system installation, if the install detects Opal-compliant hardware, the install enables full disk encryption with the encryption key stored on the OS drive. For details, see **Data Drive Requirements**.

## Auditing and Log Management

This section applies to auditing within the database application. The section does not include Linux OS host and infrastructure logs, but should have appropriate auditing controls applied.

### Audit Management

The Ocient System stores security audit logs for the database application in the `/var/log/` directory on the Linux OS host. You can see these files in that directory.

| File | Description |
|---|---|
| `rolehostd.log` | Contains all of the error, informational, and debug logs from the running database system. |
| `query.json` | Contains information on all queries and statements executed on the system. This file includes information such as the user who ran the query (or command), the time and duration, and many other details. |
| `security.json` | Contains information on both successful and unsuccessful connections to the system. |

For details, see **Log Monitoring**.

### SIEM or System Log Forwarding

Ocient recommends using a security information and event manager (SIEM) or system log (syslog) forwarder to ingest the `rolehostd.log`, `query.json`, and `security.json` audit log files located on the Linux OS host.

## Privacy

This section covers privacy controls of the database application.

### Database View Restrictions

Ocient recommends implementing database table views based on the sensitivity of the data loaded into the database application, organizational policies, and legal requirements. You can grant access to specific columns or rows to specific users and groups by using database table views. For details, see **Views**.

### Redacted Queries

The Ocient System supports redacted SQL statements in the database. Redacted text appears as `***`. For details about the privileges that control redaction, see **Data Control Language (DCL) Statement Reference**.

### Data Subject Requests

Ocient recommends using these guides to respond to data subject requests related to the General Data Protection Regulation (GDPR) or California Consumer Privacy Act (CCPA).

### Delete

To remove records from an Ocient System, see **Remove Records from an Ocient System**.

### Update

To update or rectify records in the Ocient System, see **INSERT INTO TABLE**.

# Set Up Data Encryption

Set up Ocient data encryption on TCG Opal-compliant drives using the Thales CipherTrust Manager KMS with KMIP to securely manage encryption secrets.

The Ocient® System enables you to set up data encryption on data drives that support The Computing Group (TCG) Opal Specification and store the encryption secrets in an external Key Management System (KMS) utilizing the Key Management Interoperability Protocol (KMIP). This series of workflows demonstrates generating and storing secrets using the Thales[MD] CipherTrust Manager KMS.

## Prerequisites

A KMIP server, such as Thales CipherTrust Manager, must be available to store secrets.

- The Ocient node must be a registered client of the KMIP server.
- The client certificate and key file must be on the client, e.g., `/var/opt/ocient/kmip/client.crt` and `/var/opt/ocient/kmip/client.key`.
- The CA certificate must be present on the client, e.g., `/var/opt/ocient/ca.pem`.
- The client must be able to communicate with the KMIP server.

The **SEDutil** CLI utility must be installed to manage the SED configuration of the drive. The `sedutil-cli` command must be available on the system path variable `PATH`.

Ensure all NVMe drives intended for use with Ocient are:

- Bound to the kernel NVMe driver.
- Have no partition table.
- Be in the Opal factory state.
  - Use `--revertTPer` or `--revertNoErase` SEDutil commands.
- Have these initial settings for the drives and `SIDPassword` set to `admin`:
  - `Locked = N`
  - `LockingEnabled = N`

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- `LockingSupported = Y`
- `MBRDone = N`
- `MBREnabled = N`
- `MBRAbsent = N`
- `MediaEncrypt = Y`

## Set Up Data Encryption

Use a configuration file and script to generate the secret or key.

1. Generate a configuration file with the path /var/opt/ocient/ockmip.conf. The configuration file uses the **PyKMIP** configuration file format, such as this text.

```none
[client]
host=thales01.example.com
port=5696
certfile=/var/opt/ocient/kmip/client.crt
keyfile=/var/opt/ocient/kmip/client.key
ca_certs=/var/opt/ocient/kmip/ca.pem
```

2. Run this command.

```shell
sudo /usr/local/bin/ockmip init
```

The script performs these operations for each drive that is detected as unused by the OS (no partition table present or with an Ocient partition):

- Generate a password or key for locking the drive.
- Store the secret password or key on the KMIP server.
- Enable Opal locking on the drive and set the `admin1` password to the generated secret.

© 2026 Ocient, Inc

- Set the `SIDpassword` to `admin` to enable reverting the drive to the factory state in case the `admin1` password is lost.

To enable the script to run on start before the drives are bound to the `uio` or `vfio` driver by the system `bind-uio-driver.service` installed by the `ocient` package, run this command.

Shell

```
sudo /usr/local/bin/ockmip install
```

On reboot, the `ockmip` service unlocks the drives before they are bound to the `uio` or `vfio` driver and available for use by the `rolehostd` process.

The full setup sequence is as follows:

1. Configure the `ockmip.conf` configuration file with all of the appropriate settings.
2. Stop the `rolehostd` process if it is running.
3. Unbind drives from the `uio` or `vfio` driver back to the NVMe driver.
4. If Ocient has already been bootstrapped on the node, use the `import-drives` command. Otherwise, use the `init-drives` command.

shell

```
## Ocient has been bootstrapped.
ockmip import-drives
```

shell

```
## Ocient has not been bootstrapped.
ockmip init-drives
```

5. Set the node role configuration to `useOpal: false` within the `rolehostd.conf` file.
6. Back up any existing keys in `/var/opt/ocient/localKeyStore` in case you encounter any issues.

7. Install the `systemd` service to unlock drives on the reboot.

shell

```
ockmip install
```

8. Optionally, perform a power off and power on to ensure the installation was successful and that the `ockmip.service` successfully unlocks drives on boot.

Migration process output might be similar to this output.

Text

```
[root\@ppolllercs00006 ocient]# ockmip -l DEBUG import-drives
[2024-09-12 12:45:32,853][INFO] Using conf file /var/opt/ocient/ockmip.conf
[2024-09-12 12:45:33,427][INFO] importing drive(s)
[2024-09-12 12:45:33,427][INFO] Importing secret for /dev/nvme15 BTAX240306A015PF
...
```

After reboot, the `ockmip` service output might be similar to this output.

Text

```
[root\@dpolllercs0002e log]# systemctl status ockmip
○ ockmip.service - Oneshot service to unlock NVMe drives via ockmip script using
     Loaded: loaded (/etc/systemd/system/ockmip.service; enabled; preset: disable
     Active: inactive (dead) since Wed 2024-09-11 19:11:55 UTC; 31min ago
    Process: 3217 ExecStart=/usr/local/bin/ockmip unlock (code=exited, status=0/S

...
```

The `rolehostd` process should start up without the process managing encryption because the `ockmip` service handles it.

# Troubleshooting

For more details on the possible commands, see the help using this command.

```shell
sudo /usr/local/bin/ockmip --help
```

To diagnose issues, examine the log located at `/var/opt/ocient/log/ockmip.log`

To perform actions on a particular drive or set of drives, you can manually specify with the `--drives` parameter.

```shell
sudo ockmip unlock --drives /dev/nvme1n1 --drives /dev/nvme2n1
```

### `NCERRInsufficentPermissions` Error

When attempting to register the drives, you see this error.

```text
[2024-08-26 17:27:51,350][INFO] Using conf file /var/opt/ocient/ockmip.conf [2024
```

To fix this, regenerate the certificate on the endpoint of the Thales device (as the root CA has no trust) in the Thales Administrator.

## Disk Replacement

After you swap a disk, initialize it using the `ockmip` utility to add the encryption secret to Thales.

### `ockmip.service` Status

Check the status after the boot of the system to ensure that all drives have been correctly unlocked.

# Workload Management Walkthrough

Walkthrough for configuring workload management in Ocient with service classes, query priorities, and resource limits to balance interactive and batch loads.

Workload Management (WLM) in the OcientAIQ™ Unified Data Platform allows a Database Administrator to set restrictions and priorities for groups of users. The main use case for this is to effectively control multiple workflows across the system, prioritizing or limiting resources to groups when needed. Query restrictions are set and assigned using a service class that can be used for multiple user groups. For a full list of restrictions and their definitions, see the documentation.

This example shows how to set up three service classes with differing priorities, explaining the tradeoffs and design decisions one should make when setting up these restrictions.

## Create Service Classes

Before creating service classes, the System Administrator or Database Administrator first determines the logical grouping of users on their system and their relative priority. In addition, the response time and concurrency requirements of different user groups are understood. Using these inputs, the administrator can design the service classes that allow their users to receive the proper resource allocations that deliver query requirements.

In this example, define the priority at the service level by creating three service classes to service High, Medium, and Low priority users. Different settings are configured to provide an illustration of the types of configuration that you can use to control features such as concurrency, result sizing, or scheduling priority.

### Prerequisites

1. An Ocient® System has been set up with an operational SQL Node.
2. A user with the system administrator role has access to the system

### Step 1: Login as a System Administrator User

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

To create service classes, you must have the **System Administrator** role. For a full list of user permissions and their definitions, see the **Data Control Language (DCL) Statement Reference**.

First, connect to the system database with the command.

Shell

```
connect to jdbc:ocient://my_SQL_ip_address:4050/system;user=admin@system;password=s
```

## Step 2: Set up the High Priority User Class

User groups that need fast performance and need access to the most system resources should fall under this service class. Their queries should see minimal impact from outside workloads.

> When defining a service class, the system sets any omitted service class field to the maximum or least restrictive value.

### Example Service Class

SQL

```
CREATE SERVICE CLASS high_priority_sc
  scheduling_priority = 100.0,
  max_concurrent_queries = 10,
  max_elapsed_time = 3600;
```

### Example System Catalog View

SQL

```
SELECT * FROM sys.service_classes;

id                                   database_id                          name
-------------------------------------------------------------------------------
42649e8e-ae7f-4de5-bb2b-846d158fcb91 23291ad0-ce94-4e1a-bdc9-178463ef6ec4 Default
06b92c4c-b0b1-4a14-880c-7d257af3b2b5 23291ad0-ce94-4e1a-bdc9-178463ef6ec4 high_pric
```

`scheduling_priority` — A numeric value that defines the query's priority in the database. A default query being run with no service class has a priority set to 1.0. This priority number is used as an ordered list for scheduling with higher values receiving priority. It is not a weighted value, so only the ordering, not the relative sizes of the priority levels matter. When setting the priority for a high-priority service class, set this value to be greater than 1.0.

`max_concurrent_queries` — The number of concurrent queries that can be run at a given time for the entire service class. If the max concurrency is hit, queries enter a queue. A value of -1 indicates unlimited queries, however it is a best practice to set this value so no individual workloads can monopolize the system.

`max_elapsed_time` — The maximum amount of time, in seconds, a query can run. This restriction helps reduce the length of queries holding concurrency slots and allows concurrent workloads using the same service class to all make progress. It is recommended to set `max_elapsed_time` if `max_concurrent_queries` is set to prevent extremely long-running queries from blocking other concurrent queries. If a service class needs to run sets of queries with very different expected elapsed times, it might be an indication that a separate service class is warranted.

## Step 3: Set up the Medium Priority User Class

User groups that do not necessarily need the fastest performance fall under the medium priority service class. Higher-priority queries impact the performance of queries in this service class, but these queries receive priority over lower-priority ad hoc workloads.

### Example Service Class

SQL

```
CREATE SERVICE CLASS medium_priority_sc scheduling_priority = 10.0, max_concurrent_
```

### Example System Catalog View

```sql
SELECT * FROM sys.service_classes;

id                                   database_id                          name
-----------------------------------------------------------------------------------
42649e8e-ae7f-4de5-bb2b-846d158fcb91 23291ad0-ce94-4e1a-bdc9-178463ef6ec4 Default
06b92c4c-b0b1-4a14-880c-7d257af3b2b5 23291ad0-ce94-4e1a-bdc9-178463ef6ec4 high_pric
bf3a939d-d773-4c7c-9c30-4bc14e7b9422 23291ad0-ce94-4e1a-bdc9-178463ef6ec4 medium_pr
```

`scheduling_priority` — For a “medium” priority, this value should be set to a number in-between the highest priority service class and the default service class.

`max_temp_disk_usage` — From 0-100, this field represents the maximum percentage of unused disk space that a query can see before failing. When setting up the cluster, it is important to keep some disk space unused on a Foundation Node so queries can spill to disk. Note that this percentage is tracked on a system-wide basis per node, not within a service class. As one service class uses its allocation of temporary disk space to fulfill a query, it also reduces the total temporary disk available to all other service classes. Even if those service classes have a max_temp_disk_usage set, if the total available temp disk space is below the amount needed to run a query, it can fail. For example, if a higher-priority service class is using over 50% of the unused disk space during a medium-priority query that needs to spill to disk, the medium-priority query fails during its first attempt to spill without using any disk space. Spill to disk scheduling uses the same priority used for normal execution.

## Step 4: Set up the Low Priority Service Class

User groups that are less performance sensitive fall under the low-priority service class. The design goal is for these queries to have minimal effect on other workloads. Examples of users in this service class are analysts who want to run ad hoc queries or processes that run time-insensitive background reports.

### Example Service Class

SQL

```
CREATE SERVICE CLASS low_priority_sc
  scheduling_priority = 1.0,
  max_concurrent_queries = 1,
  max_elapsed_time = 60,
  max_rows_returned = 100,
  max_temp_disk_usage = 0,
  cache_max_bytes = 0,
  cache_max_time = 0,
  max_elapsed_time_for_caching = 0;
```

### Example System Catalog View

SQL

```
SELECT * FROM sys.service_classes;

id                                   database_id                          name
-----------------------------------------------------------------------------------
42649e8e-ae7f-4de5-bb2b-846d158fcb91 23291ad0-ce94-4e1a-bdc9-178463ef6ec4 Default
06b92c4c-b0b1-4a14-880c-7d257af3b2b5 23291ad0-ce94-4e1a-bdc9-178463ef6ec4 high_pric
bf3a939d-d773-4c7c-9c30-4bc14e7b9422 23291ad0-ce94-4e1a-bdc9-178463ef6ec4 medium_pr
dd1f9f03-edff-4c7e-acd7-32997b6fceaa 23291ad0-ce94-4e1a-bdc9-178463ef6ec4 low_prior
```

`scheduling_priority` — For a low priority, this value should be set to a low number like 1.0. If a service class wants to be lower priority than default queries, it can schedule a value lower than 1.0.

`max_temp_disk_usage` — Setting this limitation to 0 means that the system does not allow any queries in the low-priority service class to spill to disk. In this example, the goal of the designer is to prevent the low-priority service class from impacting more important workloads that might need the entire temp disk space. In other cases, it could be suitable to allow low priority service class queries to use temp disk.

`cache_max_bytes`, `cache_max_time`, `max_elapsed_time_for_caching` — Result set caching is a feature that attempts to cache result sets for commonly used queries. This result set cache is shared across service classes. For a lower-priority user, it makes sense to limit the time allowed in the cache or cap the maximum number of bytes used in the cache so a higher-priority service class can take advantage of it. In this example, the

result set cache is explicitly disabled for low priority users by setting these values to zero. For details, see the **Result Set Caching**.

### Step 5: Assign Service Classes to User Groups

After setting up the service classes, you need to assign them to user groups. When a service class is assigned to user groups, users in each user group can run queries under the restrictions set for the given service class. This process can be repeated for all service classes and users.

#### Examples

SQL

```
/* Create a user group. */
CREATE GROUP low_priority_group;

/* Assign the service class to the user group. */
ALTER GROUP low_priority_group SET service class = low_priority_sc;

/* Add a user to a user group. */
ALTER GROUP low_priority_group ADD USER analyst1;
```

## Dynamic Workload Management Priority Adjustment

When a query executes, you can set the priority of a query at the service class level, database session level, or the query level. The system chooses the maximum value from these three priority levels.

While the engine executes a query, the engine can dynamically adjust the priority using a specified adjustment interval. You can change the percentage amount to dynamically adjust query priority using the `priority_adjustment_factor` (or `ADJUSTFACTOR`) and the time period that indicates the frequency for the adjustment of the query priority during query execution using the `priority_adjustment_time` (or `ADJUSTTIME`). You can override this limit at the query level or the session level.

Define the priority at the service level by creating service classes. You can override the priority at the service level by using the priority at the session or query level. For details, see **Users, Groups, and Service Classes**.

Define the priority at the session level using the command line. This code instructs the engine to dynamically adjust the priority every 15 seconds and decrease the query priority by 25%.

SQL

```
SET PRIORITY "5.0";
SET ADJUSTTIME 15;
SET ADJUSTFACTOR "0.75";
```

To reset the priority adjustment factor, enter this SQL statement.

SQL

```
SET ADJUSTFACTOR RESET;
```

Or, define the priority at the query level in the SQL statement, such as this statement.

SQL

```
SELECT * FROM table1 USING
  SCHEDULING_PRIORITY = 10.0,
  PRIORITY_ADJUSTMENT_FACTOR = 1.75,
  PRIORITY_ADJUSTMENT_TIME = 120;
```

Alternatively, you can also specify a service class to use at the query level. This example creates the service class `lower_priority` and assigns it to the query.

SQL

```
CREATE SERVICE CLASS lower_priority
  SCHEDULING_PRIORITY = 10.0,
  PRIORITY_ADJUSTMENT_FACTOR = 0.75,
  PRIORITY_ADJUSTMENT_TIME = 120;

SELECT * FROM table1 USING SERVICE CLASS lower_priority;
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

If you do not identify a specific service class for a query with the `USING SERVICE CLASS` clause and the query does not match any service classes that use the `STATEMENT_TEXT` parameter, the query uses a composite of least restrictive parameters allowed by the service classes eligible for the query.

Using a service class at the query level requires a user to be assigned to a user group that is included in that specific service class.

## Low-Latency Settings

Low-latency service class settings are intended to reduce runtime overhead for classes of subsecond queries with minimal processing work. Classes of queries that are good candidates utilize indexes on their filters, have low cardinality, and perform minimal work, such as simple aggregations or scalar functions. Low-latency service class settings might hinder query performance when queries have high cardinality or perform computationally intense work. Workload management is key to isolating these simple, low-latency queries to specific service classes where you can apply these optimizations in isolation.

Queries for latency-sensitive applications, such as populating live dashboards and key-value retrieval might benefit from service-class level settings that help the Ocient System to make runtime choices to reduce latency. These choices often help queries with low cardinality and minimal computational work, but they can be detrimental to queries that violate these assumptions. Database administrators should use service classes to isolate low-latency components of a system from computationally intensive components.

A system administrator can turn on one simple or two advanced settings.

| Setting | Description | Value |
|---|---|---|
| `LOW_LATENCY` | This optional service class setting enables you to control the `HALF_PARALLELISM` and `LOAD_BALANCE_SHUFFLE` settings. When you set this setting to `true`, it is equivalent to setting `HALF_PARALLELISM = true` and `LOAD_BALANCE_SHUFFLE = false`. When you do not set this setting or set it to `false`, the Ocient System clears the `HALF_PARALLELISM` and `LOAD_BALANCE_SHUFFLE` settings. | Optionally set to `true` or `false`. The default value is unset. |
| `HALF_PARALLELISM` | This optional service class setting controls execution parallelism overrides. When you do not set this setting, the system uses cost-based heuristics to determine runtime parallelism. When you set this | Optionally set to `true` or `false`. The default value is unset. |

| Setting | Description | Value |
| --- | --- | --- |
| | setting to `true`, the system always uses half parallelism for queries that match this service class. When you set this setting to `false`, the system always uses full parallelism for queries that match this service class.<br>Half parallelism can help latency by reducing the amount of administrative work the system needs to do to run a query, but it reduces the computational power allocated to the query. | |
| `LOAD_BALANCE_SHUFFLE` | This optional service class setting controls load balancing shuffles above I/O operators. When you do not set this setting, the Ocient System uses statistics-based heuristics to determine whether to use load balance shuffles. When you set this setting to `true`, the system always performs a load balance shuffle for queries that match this service class. When you set this setting to `false`, the system never performs a load balance shuffle for queries that match this service class.<br>Load balance shuffles are useful for distributing uneven data distributions on disk, which can occur during live-loading of tables or small cardinality tables with compute-heavy computations. However, this load balancing incurs some system-coordination overhead, which hampers low-latency queries. | Optionally set to `true` or `false`. The default value is unset. |

There is further convenience for organizing these parameters in a service class by enclosing `HALF_PARALLELISM` or `LOAD_BALANCE_SHUFFLE` settings in a `LOW_LATENCY` key-value setting map.

SQL

```
CREATE SERVICE CLASS ll_service_class
  LOW_LATENCY = {HALF_PARALLELISM = true,
                 LOAD_BALANCE_SHUFFLE = true};

SELECT * FROM table1 USING SERVICE CLASS ll_service_class;
```

## Other Service Class Considerations

Service classes are a powerful tool to properly allocate resources in the database to the users that need them most. When deciding on the restrictions for your individual use case, consider the total number of service classes that the system creates. Some settings

like `max_concurrent_queries` and result set caching values like `cache_max_bytes` and `cache_max_time` can have a cumulative effect on resource availability as the number of service classes increases. For details about result set caching, see **Result Set Caching**.

For example, concurrency limitations are set on an individual service class level. While the intention might be to limit low priority service classes to only a couple of concurrent queries, the total effect of many service classes with a couple of concurrent queries each can start to affect high priority workloads due to the number of concurrent queries running across all lower priority service classes.

# Workload Management and Service Classes

Use Ocient workload management and service classes to prioritize queries, allocate CPU and memory, and enforce concurrency limits across users and applications.

Service classes define limits on groups in the Ocient® System. You can design service classes using these limits. Use these parameters to control the limits.

| Parameter | Description | Values |
|---|---|---|
| `MAX_TEMP_DISK_USAGE` | Limit the percentage of temporary disk space used by the total service class relative to the amount of remaining free space. If all running queries for a particular service class exceed the given percentage, queries fail. | A percentage integer from 0-100. |
| `MAX_ELAPSED_TIME` | Limit query runtime. The database process kills any queries that exceed this limit. | -1 for unlimited, or a positive integer for the number of seconds. |
| `MAX_CONCURRENT_QUERIES` | Limit the maximum number of queries that can run concurrently for a given service class. The database process queues additional queries. | -1 for unlimited, or a positive integer for the number of queries. |
| `MAX_ROWS_RETURNED` | Limit number of rows returned by a query. The database process kills queries that exceed this limit. | -1 for unlimited, or a positive integer for the number of rows. |
| `MINIMIZE_QUERY_DEBUG_RECORDS` | Stop the load of the `sys.completed_operator_instances` system catalog table and the generation of specific debug logs associated with the query. | Boolean `true` for minimizing the capture of metadata and logs, and `false` or unset (default) for capturing this data. |
| `SCHEDULING_PRIORITY` | Limit initial effective query priority. | Any decimal value between the `MIN_PRIORITY` and `MAX_PRIORITY`. |
| `CACHE_MAX_BYTES` | Maximum number of bytes in a result set if the result set can be stored in the cache. This value is the number of bytes in the wire- | -1 for none, or a positive integer for the number of bytes. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Parameter | Description | Values |
| --- | --- | --- |
| | protocol representation, or what is sent to a client. | |
| `CACHE_MAX_TIME` | Maximum time rows are cached. | -1 for none, or a positive integer for the number of seconds. |
| `MAX_ELAPSED_TIME_FOR_CACHING` | Maximum elapsed time for caching. If you set this parameter, queries that exceed maximum elapsed time return no results, but continue to run in the background until either the query reaches the maximum elapsed time for caching or the query successfully completes and caches the result set. For details, see documentation. | -1 for none, or a positive integer for the number of seconds. |
| `MAX_COLUMNS_IN_RESULT_SET` | Limit number of columns returned by a query. The database process kills queries that exceed this limit. | -1 for unlimited, or a positive integer for the number of columns. |
| `PRIORITY_ADJUSTMENT_FACTOR` | Percentage amount to adjust query priority. You can override this limit at the query level or the session level. Formula is: `(new_priority = current_priority * priority_adjustment_factor)` | 0 to disable dynamic priority adjustment (default), or a positive double value that is greater than 0. Values less than 1 decrease priority over time until the priority reaches the service class minimum priority, while values greater than 1 increase priority over time until the priority reaches the service class maximum priority. |
| `PRIORITY_ADJUSTMENT_TIME` | Time period that indicates the frequency for the adjustment of query priority during execution of the query. You can override this limit at the query level or the session level. | 0 to disable dynamic priority adjustment (default), or a positive integer (unsigned 32-bit integer) for the number of seconds that is greater than 0. |
| `MIN_PRIORITY` | Limit the minimum query priority. The current effective priority cannot be smaller than this value. | 0 (default) or any decimal value (double) greater than 0. |
| `MAX_PRIORITY` | Limit the maximum query priority. The current effective priority cannot be greater than this value. | -1 (default) that indicates infinity or any decimal value (double) greater than 0. |
| `STATEMENT_TEXT` | The system uses the specified service class for any queries that match the specified text pattern. The system uses service classes with statement text before any | A string that uses either LIKE or REGEX pattern matching.<br>For example, `STATEMENT_TEXT REGEX ".*my_table.*\|.*your_table.*"` would |

| Parameter | Description | Values |
| --- | --- | --- |
| | service classes that lack statement text.<br>If there are multiple service classes with statement text available, the system attempts to match them in alphabetical order. This matching allows you to set up service classes so that the system can assign certain query types automatically to higher-priority service classes. | match any queries that include the strings `my_table` or `your_table`. |
| `LOW_LATENCY` | Optional settings that enable you to manage low-latency service classes. | Boolean `true` or `false`, or a Key-Value setting map. |
| `MEMORY_OPTIMAL_STRATEGY` | Direct the Ocient System to reduce query memory usage, even if the operation might increase execution time. Contact Ocient Support when you change this parameter. | Boolean `true` instructs the system to apply stricter scheduling and execution rules to minimize memory consumption and avoid excessive concurrent usage. Otherwise, setting this parameter to `false` instructs the system to disable such strategies, even if the service class default enables them. By default, this parameter is unset. If you leave this parameter unset, the system reverts to higher-level default behavior or other service class settings. |

## Service Class Setting Applicability

When a user is present in multiple groups with different service class limits, the system applies the least restrictive limit for each parameter. For example, if User A is in groups G1 and G2, which have service class time limits of 10 seconds and 20 seconds, when User A runs a query, the query has a time limit of 20 seconds. This behavior is slightly different for concurrency. If the service class concurrency limits for the groups the user belongs to are 1 and 2, a query can use a concurrency slot from either service class. A user with multiple service classes can experience a query executing with a slot from one service class but using a time limit or other limits from a different service class. Additionally, the system does not apply service class concurrency limits when a query affects only system tables.

## Choose Parameter Values

If you set a service class at the session or query level, the system uses the value set by that service class, with the query-level service class taking precedence.

Otherwise, if you set a value for this parameter at the session or query level, the system uses the most restrictive of the two.

If the Ocient System chooses the value from multiple service classes, the system takes the least restrictive value from all service classes. Then, the system takes the most restrictive of that value and the query or session level value, if it exists.

> This selection does not hold true for parameters related to result set caching: `cache_max_time` and `cache_max_bytes`. For details about the behavior, see **Result Set Caching**.

If you choose a service class using statement text matching, the system compares its value to the query or session level value, and the system does not review any other service classes.

## Next Steps

A tutorial for designing a set of service classes for workload management is available in the **Workload Management Walkthrough**.

See **Users, Groups, and Service Classes** for service-class-related DDL statement references, such as creating, altering, and applying a service class.

# Result Set Caching

Use result-set caching in Ocient to accelerate repeated queries by returning cached results, with controls for cache invalidation, size, and per-query options.

The OcientAIQ™ Unified Data Platform allows query result sets to be cached on the server and returned quickly on subsequent queries. The service class under which the query executes manages result set caching. As with other service class attributes, you can override this by using keywords on the query.

## When to Use Result Set Caching

In general, result set caching is most advantageous for queries that require high processing to produce a small result. For example, a query that uses aggregate functions, such as finding the average over many rows, would be a good candidate for result caching.

To help evaluate whether to use result set caching, you can examine your query metadata, such as storage cost and processing time. To view these metrics and to see which are stored in cache, query the **sys.completed_queries** table.

## Query Matching Behavior

Result set caching uses the normalized text of the query (i.e., with comments removed, whitespace reduced, and case normalized) to determine whether two queries match. If they match, the system uses the cached result of a previous query.

> Query matching requires strict text matching. Queries cannot use cached results if they have different values for arguments such as time ranges or other filters.

## Configuring Query Caching

You can configure caching behavior for the service class (see **SERVICE CLASS**) or for an individual query (see **USING**).

You can specify configurations for result set caching with these attributes:

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| | |
|---|---|
| `cache_max_bytes` | **Controls whether the database stores the results of any specified query in the cache.**<br>**All queries executed using a service class specifying this attribute have their results stored in the cache if the size of the result is smaller than this value. You can determine the size of a result set in bytes by querying the `bytes_returned` field of the `completed_queries` virtual table. The default value is 0, and thus by default, the database does not cache any results.**<br>**The database caches results in memory on the SQL Nodes. These results are not cached if there is insufficient memory available.** |
| `cache_max_time` | Affects whether a specified query uses results from the cache rather than executing the query. If there is a cached result with the same query text, executed less than `cache_max_time` seconds ago, the database uses that cached result. The default value is 0, and thus by default, the database does not return any cached results.<br>The cache considers all SQL Nodes, and if a potential cached result is only available on a different SQL Node, the database redirects the query to that node. If you specify the force attribute on the connection, which disables load balancing and redirection, the database considers only cached results on the current node. |

When a specified query uses multiple service classes, the system uses the most restrictive configuration values. For example, if a query uses `service_class_a` with `cache_max_bytes` set to 512 and `service_class_b` with `cache_max_bytes` set to 0, the system does not cache the results. This is because 0 is the most restrictive value, and caching is disabled regardless of the result set size.

You can override the values for `cache_max_bytes` and `cache_max_time` at query time by specifying them in the query itself.

### Query Override Example

SQL

```
SELECT COUNT(*) FROM TRADES USING CACHE_MAX_BYTES=32, CACHE_MAX_TIME=60;
```

This example states that the query result is cached if it is less than or equal to 32 bytes, and the cache is used if the value stored in the cache is less than 60 seconds old. It is very important to note that attributes specified on the query cannot increase the values from the service classes, only reduce them.

Both `cache_max_bytes` and `cache_max_time` can be explicitly not specified in a service class by using the value -1. -1 is effectively treated as 0 if not overridden. `unspecified`, or -1 values can always be overridden by other service classes or on the query. A typical use case is to:

- Specify `cache_max_bytes` as 0 for service classes used by ad hoc queries, where results should never be cached and consume memory.
- Specify `cache_max_bytes` and `cache_max_time` as -1 on service classes used by repeated production queries. As mentioned, the system treats these as 0 if not overridden.
- Explicitly override `cache_max_bytes` on repeated production queries whose results should be cached.
- Explicitly override `cache_max_time` on repeated production queries whose results can be retrieved from the cache.

Note that because the default schema used for a query can affect the results of the query, the system treats two queries with identical text but making use of different schemas differently.

Finally, the contents of the cache can be examined using the `result_cache` virtual table.

## Max Elapsed Time For Caching

The system cancels queries when they exceed the `max_elapsed_time` service class value. An additional service class value, however, allows queries to continue beyond `max_elapsed_time` so that their results can be stored in the cache. The service class (or SQL) can specify `max_elapsed_time_for_caching`, which should be a value larger than `max_elapsed_time`. This value indicates the total time the query can continue executing such that its results are stored in the cache.

`max_elapsed_time_for_caching` and `max_elapsed_time` are both measured in seconds. When a query with `max_elapsed_time_for_caching` exceeds `max_elapsed_time`, a warning indicating `Query exceeded time limit, but will continue to run and be cached (Limited to 200 second(s) for caching from query)` is returned to the JDBC driver, where `max_elapsed_time_for_caching` was set to 200 seconds in this example.

`max_elapsed_time_for_caching` is only supported on queries executed using the JDBC driver.

© 2026 Ocient, Inc

# Manage the Result Set Cache

You can store and retrieve query results from the cache depending on the settings of the `cache_max_bytes` and `cache_max_time` values, either using the SQL statement or the service class specified for the query execution.

To view all cached queries and their service classes, query the **sys.result_cache** system catalog table.

You can invalidate the result set cache using these DDL statements. Use these statements when you perform table updates, such as an `INSERT INTO` SQL statement operation or the execution of one of the loading and transformation functions.

### Syntax

Remove the cached result sets for all queries that reference the specified table.

You can invalidate the cached result sets for only tables where you have the `INSERT` privilege. If a cached query references multiple tables, you only need the `INSERT` privilege on any one of those tables.

SQL

```
ALTER TABLE table_name INVALIDATE CACHE [SPREAD_OVER_TIME seconds]
```

| Parameter | Data Type | Description |
|---|---|---|
| `table_name` | string | Name of the database table. |
| `seconds` | numeric | Number of seconds that specifies the interval at which to invalidate a section of the result set cache. |

### Example

This example immediately invalidates the cache and removes the cached result sets for all queries that reference the `employees` table.

SQL

```
ALTER TABLE employees INVALIDATE CACHE;
```

This example invalidates the cache entries for queries that reference the `employees` table for a fraction of the cache every second. Specify the fraction to be 1/10 by using the `spread_over_time` parameter. The database removes 1/10 of the cached result set immediately, then the next 1/10 of the cached result set the subsequent second, and so on. Invalidation causes the re-execution of queries to delay. Spreading the invalidation over time prevents spikes of expensive query executions.

SQL

```
ALTER TABLE employees INVALIDATE CACHE SPREAD_OVER_TIME 10;
```

### Syntax

Remove the cached result sets in the specified database.

SQL

```
ALTER DATABASE database_name INVALIDATE CACHE [SPREAD_OVER_TIME seconds]
```

| Parameter | Data Type | Description |
|---|---|---|
| `database_name` | string | Name of the database. |
| `seconds` | numeric | Number of seconds that specifies the interval at which to invalidate a section of the result set cache. |

### Example

This example immediately invalidates the cache and removes the cached result sets in the `test_database` database.

SQL

```
ALTER DATABASE test_database INVALIDATE CACHE;
```

This example invalidates the cache entries in the `test_database` database for a fraction of the cache every second. Specify the fraction to be 1/10 by using the `spread_over_time` parameter. The database removes 1/10 of the cached result set immediately, then the next 1/10 of the cached result set the subsequent second, and so

on. Invalidation causes the re-execution of queries to be delayed. Spreading the invalidation over time prevents spikes of expensive query executions.

```sql
ALTER DATABASE test_database INVALIDATE CACHE SPREAD_OVER_TIME 10;
```

# Object-Type Level Privileges Management

Grant, verify, and revoke object-type level privileges in Ocient with step-by-step SQL workflows for controlling access to views in a database.

You can assign privileges at different levels of granularity on system and database objects to control access for users in the Ocient® System. The levels are:

- All objects of the specified object type in the system
- All objects of the specified object type in the database
- Specific object

This series of workflows shows how you can manage access to the `VIEW` privilege for all views (where a view is the object type) in a specified database.

## Grant Privileges

This workflow creates a group and grants the `VIEW` privilege to all views and the ability to read the views in the database to the group.

1. Create the `view_analyst` group. You can see the created group using the `sys.groups` system catalog table.

```
SQL

CREATE GROUP "view_analyst";
```

2. Grant the `VIEW` privilege for views on the `test` database to the `view_analyst` group.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

```sql
GRANT VIEW VIEW ON DATABASE "test" TO GROUP "view_analyst";
```

3. Grant the `SELECT` privilege on the database to the group.

```sql
GRANT SELECT ON DATABASE "test" TO GROUP "view_analyst";
```

4. View the granted privileges using the `sys.privileges` system catalog table. The Ocient System grants the `USE` privilege on the database implicitly.

```sql
SELECT privilege, privilege_target, object_type,
    grantee, grantor
FROM sys.privileges
WHERE grantee = 'view_analyst' and grantor != 'view_analyst';
```

*Output*

```
privilege                                          privilege_target
-------------------------------------------------------------------------------
VIEW                                               VIEW
USE                                                NULL
SELECT                                             NULL

Fetched 3 rows
```

## Verify Privileges

This workflow creates a user, assigns this user to the created group, and creates a view with generated data. The workflow shows the information that the user has access to in the database based on the granted privileges.

1. Create the `test_user` user.

SQL

```
CREATE USER test_user PASSWORD='**';
```

2. Add the user to the `view_analyst` group.

SQL

```
ALTER GROUP "view_analyst" ADD USER test_user;
```

3. Create the `view` view that selects five generated rows.

SQL

```
CREATE VIEW "test"."view" AS (SELECT * FROM sys.dummy5);
```

4. Connect to the database at the `10.10.1.1` IP address with port number `4050` as the `test_user` user.

Shell

```
connect to jdbc:ocient://10.10.1.1:4050/test;user=test_user;password=**;
```

5. View the privileges of the user using the `sys.privileges` system catalog table. This user has no privileges of their own.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT privilege, privilege_target, object_type, grantee, grantor
FROM sys.privileges
WHERE grantee = 'test_user' AND grantor != 'test_user';
```

*Output*

Text

```
privilege                                          privilege_target
-------------------------------------------------------------------------------
Fetched 0 rows
Warning: No data found
```

6 See the metadata for views that the user has access to within this database. The user has access to the `test` view only.

SQL

```
SHOW VIEWS;
```

*Output*

Text

```
table_catalog                                      table_schema
-------------------------------------------------------------------------------
test                                               test

Fetched 1 row
```

7 Verify that the user can select the data in the `view` view.

SQL

```
SELECT * FROM "test"."view";
```

*Output*

Text

```
c1
-----------
1
2
3
4
5

Fetched 5 rows
```

# Manage Users, Groups, and Roles

Manage users, groups, and roles in Ocient with SQL DCL statements to enforce role-based access control over databases, tables, views, and other objects.

The OcientAIQ™ Unified Data Platform can have one or more databases, each of which can run multiple applications. Administrators have the ability to define and manage users in Ocient® to meet the needs of a multi-tenant environment. Through user, group, and role management capabilities in Ocient, administrators can make sure that users only have privileges to the objects and databases they need. They can also set security settings for passwords. For details, see **Database Password Security Settings**.

## Users

Users in Ocient are represented by a username and password. They can have privileges to the system or one or more databases within the system. Privileges of a user can be granted directly to the user or inherited through groups or roles. Users can also belong to zero or many groups and can have zero or many pre-defined roles in the system. A user identifier might be used by someone logging directly into Ocient through the Ocient command-line interface (CLI) or by an application connecting to a database.

The `sys.users` system catalog table displays information about users in the database.

### Fully Qualified User Names

A Fully Qualified User Name (FQUN) is the combination of a username and the database on which the user was created. For example: `jsmith@metrics`. It is not mandatory for users to use an FQUN to connect to their own database.

An FQUN uniquely identifies a user and follows the pattern `"<user_name>@<database_name>"`, where `<user_name>` is the username and `<database_name>` is the name of the database. Use an FQUN to reference a user associated with a database other than the one you are connected to.

| user id | user name | database name | fully qualified user name (FQUN) |
|---|---|---|---|
| 000 | alice | db1 | alice@db1 |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| user id | user name | database name | fully qualified user name (FQUN) |
|---|---|---|---|
| 001 | alice | db2 | alice@db2 |
| 002 | jimmy | system | jimmy@system |

If you do not specify an FQUN when you reference a user object, Ocient assumes the user is associated with the database of the active connection.

This example shows the intended use of the FQUN and how the database is implicitly selected when you connect to the database.

Given an Ocient System with two databases, `operations` and `metrics`, create two administrator users and give administrator rights to each on their respective database.

| FQUN | Database | Password |
|---|---|---|
| admin@operations | operations | password1 |
| admin@metrics | metrics | password2 |

These are two separate users. Those users can set up their database for the remainder of their users, including:

- Create users with various roles and privileges.
- Set up SSO controls for each database.
- Create tables.
- Create pipelines to load data.
- Create service classes.

It is not mandatory for users to use an FQUN to connect to their database. The first user can connect to the `operations` database as the user `admin` with `password1`. The system treats this login as the user `admin@operations`.

Similarly, the second user can connect to the `metrics` database as the user `admin` with `password2`.

In this example, neither user has to use their FQUN, because they only work with the database described by their FQUN.

When you have permission to connect to more than one database, you must use your FQUN for any database that does not match your FQUN. For example, if the user `jsmith@metrics` also has access to the `auctions` database, then that user can connect with their FQUN `jsmith@metrics`.

# Groups

A group is a collection of users that has a set of privileges assigned to it. Administrators can create groups that represent an application or a specific job role for users within the database. For example, a group named `US_Analysts` might only have privileges that allow access to data from the US. Groups belong to individual databases. In other words, you cannot define a group with privileges that span multiple databases.

A service class defines a set of limits on groups. The database applies service classes on a per-group basis. By default, all groups are in the `DEFAULT` service class that has no limits. For details, see **Workload Management and Service Classes**.

The `sys.groups` system catalog table displays information about groups in the database. You can also use the **CURRENT_GROUPS** function to view the fully-qualified names of the groups in the database.

# Roles

Similar to groups, users can inherit privileges by being granted one of the pre-defined roles in Ocient. The system pre-defines the names of and privileges assigned to roles in Ocient. Roles can apply to the Ocient System or one of the user-defined databases.

## System Roles

- **Security Administrator** — Can read, create, and modify all users or groups.
- **System Administrator** — Can read, create, and modify system objects such as tables, clusters, databases, etc. Can also kill running queries system-wide.
- **System Analyst** — Read-only access to the entire system.

You can grant system roles to individual users whether they are members of a specific User Database or defined on `system`.

## Database Roles

- **DB Public** — Can grant and distribute privileges using this `PUBLIC` role. Every user created in the database has this role.
- **Database Administrator** — Can read, create, and modify database objects such as tables, clusters, databases, etc. The database administrator can also create users for the database and kill running queries.
- **Database Analyst** — Read-only rights to database objects and data within the database.

These roles are named with the convention `"<database_name> <role_name>"`, where `<database_name>` is the name of the database and `<role_name>` is the name of the role. The `sys.roles` system catalog table displays this information.

To learn about the syntax for granting privileges, see **Data Control Language (DCL) Statement Reference**.

## Use DCL to Assign User Privileges

To assign or revoke privileges to users, administrators can use Data Control Language (DCL) statements. You can execute DCL statements like any other SQL statements against the Ocient System and databases. These statements allow for quick and easy modification of user access. For details, see the **Data Control Language (DCL) Statement Reference**.

### System Database

Every Ocient System includes an administration interface named `system`.

The Ocient System lists `system` as a database, but it is not actually an active database. `system` serves as a connection point for administration, particularly during the initial system setup to configure other databases, storage, user access, and other configurations.

When connected to `system`, users can see metadata for all User Databases to which they have rights. Only users who have System Administrator or System Analyst roles can see metadata for Nodes, Node Service Roles, storage spaces, and storage clusters.

A user can log into `system` if any of these conditions are true:

- You create the user on that database — e.g., `johndoe@system.`

- You assign the user the role of either System Administrator or System Analyst.
- The non-system user (e.g., `myuser@some_database`) has been granted `SYSTEM` privileges through DCL, e.g., `GRANT USE on SYSTEM to USER some_user@some_database;`

### User Databases

User Databases are defined by users. These databases can house tables, views, and data. You can create and scope users to a database to allow multi-tenancy on an Ocient System or limit the ability of users to see the data or schemas defined in other User Databases.

When you connect to a user database, you can query the user data in this database and see the metadata for this database in system tables.

### Visibility of Catalog Components Based on User Privileges

All system catalog tables (e.g., `sys.tables`, `sys.users`, `sys.databases`) are queryable to all users of Ocient regardless of their connection. The contents of these tables can change based on the rights that the individual user has. For example, if a user is blocked from a specific database, then a query on the system catalog by that user would not show that database or any of its objects.

# Authentication Methods

Overview of authentication methods supported by Ocient, including database password, single sign-on (SSO), OpenID Connect, and token-based access.

Ocient® offers two authentication methods to access the database: Password authentication and Single Sign On (SSO) authentication. You can use these independently or as an organization according to your security and access control needs. This section explains each authentication method and how it can be configured on Ocient.

## Password-Based Authentication

Users created using DCL are required to set a password that the system uses for authentication when connecting to the database.

Administrators can use **Database Password Security Settings** to manage settings such as minimum password length and password expiration policies.

### Fully Qualified User Name (FQUN)

To connect to the database, you must provide an FQUN. For database users, the FQUN has this form.

```
Text
<user_name>@<database>
```

For example, the FQUN of the user `alice`, a member of the database `example_database`.

```
Text
alice@example_database
```

### How To Connect using Password Authentication

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Set the FQUN in the connection string along with the password of the user. For example, this code is the command `alice` uses to connect to `example_database` using the Ocient JDBC driver.

Text

```
connect to jdbc:ocient://<host>:<port>/example_database;user=alice@example_database
```

The following Ocient driver properties must be set when connecting using password authentication:

- user — `alice@example_database`
- password — “

## Single Sign On (SSO)

The Ocient System allows administrators to add a Single Sign-On integration, allowing users to authenticate using an external Identity Provider (idP). A database, including the `system` database, can have 0 or 1 SSO integrations.

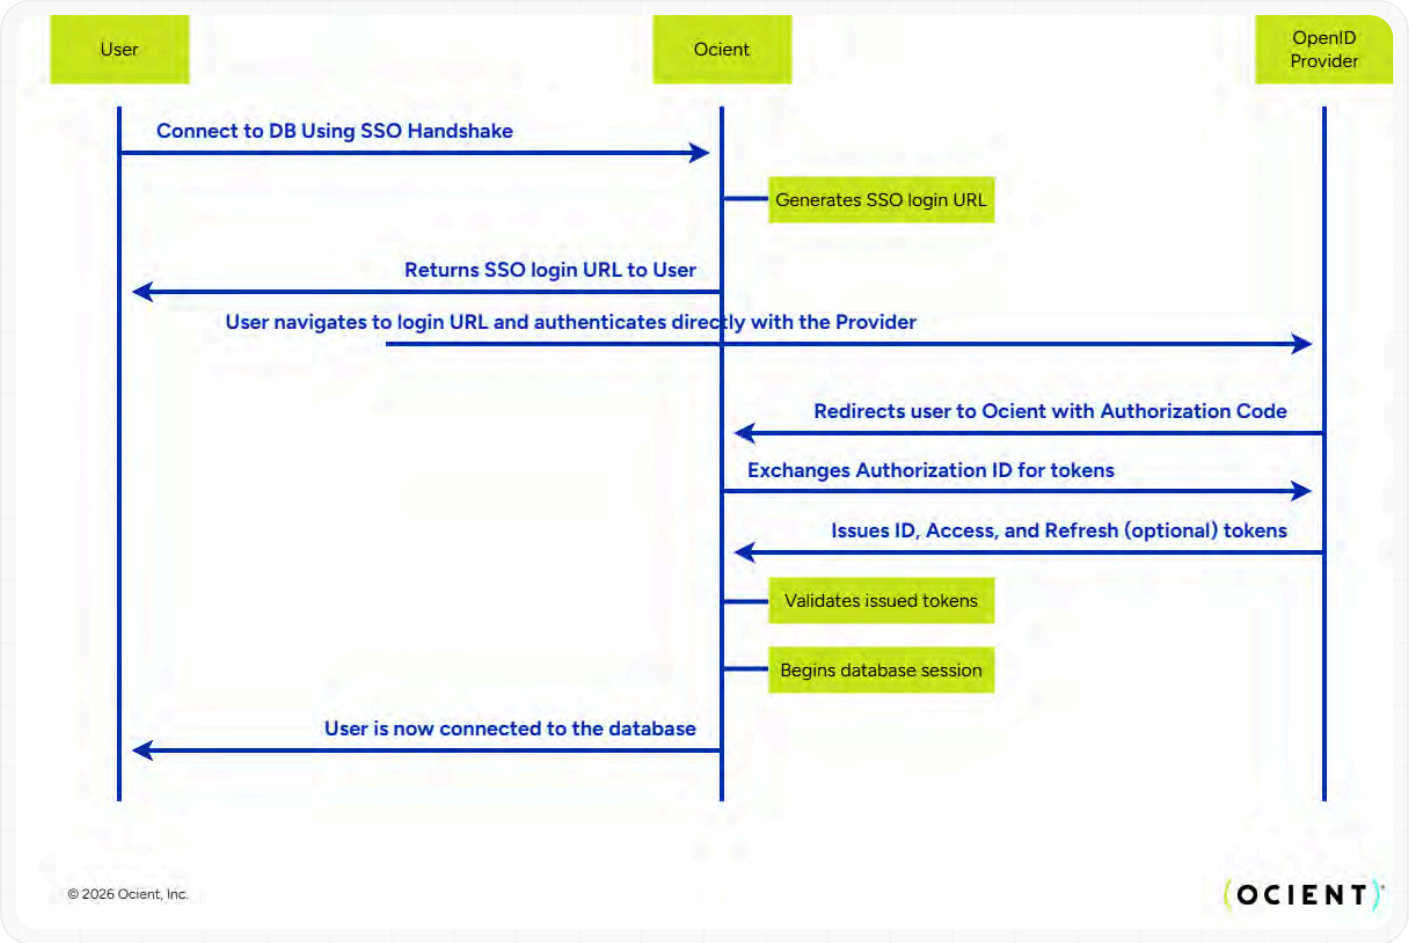
> The existence of an SSO integration has no effect on users who authenticate with the Password Authentication flow.

**Supported Protocols:**

The Ocient System supports the following SSO protocols:

| Protocol | Description |
| --- | --- |
| **OpenID Connect** | OpenID Connect (OIDC) is a simple JSON-/REST-based identity protocol built on top of the OAuth 2.0 protocol. It enables client applications to rely on the authentication performed by an OpenID Connect Provider to verify the identity of a user. Clients can also obtain basic profile information about a user in an interoperable and REST-like manner from OpenID Connect Providers. |

## OpenID Connect



There are two flows that allow users to connect to the database using an external OpenID Connect Provider.

## Authorization Code Flow

This is the most commonly used authentication method and makes use of the **OAuth 2.0 Authorization Code Grant**.

When you connect to the database, the Ocient driver directs you to the authorization endpoint of the OpenID Provider, where you log in with your SSO credentials. After the Provider authenticates you, it redirects you back to the database with a temporary code, which the database exchanges for an ID token, Access token, and optionally, a Refresh token.

See this image for a sequence diagram of the flow.

### Connect using the Authorization Code Flow

The client handshake method must be set to SSO, and the connection username and password set to the empty string.

For example, this code is the command any user would use to connect to the `example_database` database using the Ocient JDBC driver.

Text

```
connect to jdbc:ocient://<host>:<port>/example_database;handshake=SSO;user=;passwor
```

These Ocient driver properties must be set when connecting using the Authorization Code flow:

- handshake — `SSO`
- user — `<empty_string>`
- password — `<empty_string>`

> The `user` and `password` properties are required and must be set to the empty string.

## SSO Token Flow

Users can provide either an **ID Token** or an **Access Token** issued by the OpenID Provider to connect to the database.

The provided ID or Access token must contain these claims:

- iss — The issuer must match the issuer contained in the discovery document of the OpenID Provider.
- aud — The token audience must contain the `client_id` used when configuring the OpenID Provider in the database.

> Ocient recommends including the `email` scope in any token provided to Ocient. The system uses the value of the email claim to identify the user in the database audit trails.
>
> Ocient supports these signing algorithms for ID Tokens:
>
> - RSA 256
> - RSA 384
> - RSA 512

### Connect using the SSO Token Flow

These Ocient driver properties must be set when connecting using an OpenID token:

- handshake — `SSO`
- user — `id_token` or `access_token`
- password — `<token_data>`

The handshake must be set to SSO, with the username set to the token type and the password set to the token payload.

For example, this format is the JDBC command to connect to the `example_database` database using an ID Token.

Text

```
connect to jdbc:ocient://<host>:<port>/example_database;handshake=SSO;user=id_token
```

This format is the JDBC command to connect to `example_database` database using an Access Token.

Text

```
connect to jdbc:ocient://<host>:<port>/example_database;handshake=SSO;user=access_t
```

## Configure the OpenID Provider

Before users can authenticate using SSO, you must register the database with the OpenID Provider. This process varies depending on the provider, but typically, the steps for doing so are:

1. Create an application for the Ocient System in the Provider. Select the “Native Application” application type.
2. Enable the Authorization Code, Refresh Token, and Device Authorization grant types.
3. Grant permission to the appropriate users to use the newly created application.
4. Enter this Redirect URI.

| Application | Redirect URI |
| --- | --- |
| JDBC Driver | `http://localhost:7050/ocient/oauth2/v1/callback` |

| Application | Redirect URI |
| --- | --- |
| OpenAPI or UI | `https://<advertised_ip>/v1/callback` |

> For the OpenAPI or UI application, the redirect URI must use `https` format.
>
> The connectivity pool defines the OpenAPI or WebUI `advertized_ip` setting. For more information, see **CONNECTIVITY POOL**.

Record the token `issuer` and `client_id` of the newly created application. You need these values to configure the Ocient System.

## SSO Parameters

These SSO parameters are configurable by using DDL statements.

| Name | Required | Value Type | Default Value | Description |
| --- | --- | --- | --- | --- |
| `issuer` | Yes | string | None | The **complete U** for the OAuth 2.( and OpenID Connect Authorization Server. This property value is the expected `\"iss\"` claim i access tokens validated by the database. |
| `client_id` | Yes | string | None | The **client identifier** as registered with t OpenID Provider. |
| `client_secret` | Yes | string | None | The **client secr** as registered wit the OpenID Provider. This property is requi for some SSO workflows. |
| `default_group` | Yes | string | None | The group users assigned if no group is specifie the |

| Name | Required | Value Type | Default Value | Description |
| --- | --- | --- | --- | --- |
| | | | | `group_claim_map` `gs` property for the OpenID Provider. |
| `redirect_host` | No | string | Depends on the connector (pyocient or JDBC). | Specifies the hos name during SS redirection. |
| `redirect_ssl` | No | Boolean | Depends on the connector (pyocient or JDBC). | Set to `true` to enable SSL callb during SSO redirection (i.e., redirect uses `https`). Set to `false` to disable (i.e., redirect uses `http`). |
| `disabled` | No | Boolean | `false` | Set to `true` to disable the OIDC integration for maintenance temporarily. ⚠ If you set this property to `true` all authentication requests using th connection fail. |
| `enable_id_token_au` `thentication` | No | Boolean | `false` | Set this property `true` if the identifier token a contains the authorization tok In most circumstances, t option is necessa only for machine to-machine connections with user interaction, such as a server using a script to connect to an Ocient System. |
| `user_id_claims` | No | list of strings (e.g., value [, ...] | [“email”] | Set the claims us to identify users audit trails. The system resolves |

| Name | Required | Value Type | Default Value | Description |
| --- | --- | --- | --- | --- |
| | | | | specified claims from both the ID token and the userinfo endpoin response. If you not set a value, t system uses the `"email"` claim i is present, otherwise it uses `["iss", "sub"]` |
| `additional_scopes` | No | list of strings (e.g., value [, ...] | [] | Specifies additio scopes to reques when executing Authorization Co Flow. |
| `additional_audienc es` | No | list of strings (e.g., value [, ...] | [] | Specifies additio audiences to acc when validating tokens. This property is usefu for authorization servers without t token exchange capability. Each additional audience is a cas sensitive URL fro a provider, simila to the `issuer` value. |
| `groups_claim_ids` | No | list of strings (e.g., value [, ...] | [] | Specifies the tok claims that can b used to map the user to a Databa group. If you specify the `groups_claim_ma ngs` property, y must also specify the `groups_claim_id` property. |
| `groups_claim_mappi ngs` | No | map of strings (e.g., key = value [, ...]) | | Specifies mappir from the Provide group to the Database group. |

| Name | Required | Value Type | Default Value | Description |
| --- | --- | --- | --- | --- |
| `roles_claim_ids` | No | list of strings (e.g., value [, ...] | [] | Specifies the tok claims that can b used to map the user to a Databa role. If you speci the `roles_claim_map gs` property, yo must also specify the `roles_claim_ids` property. |
| `roles_claim_mappin gs` | No | map of strings (e.g., key = value [, ...]) | | Specifies mappir from the Provide role to the Database role. |
| `allowed_groups` | No | list of strings (e.g., value [, ...] | [] | Specifies a list of external identity provider groups that are permitte to authenticate through this SSO integration. If yo specify the `allowed_groups` property, only us who are membe of the specified identify provider groups can acce the Ocient Syste<br><br>If this property is empty or you do not specify it, the group-based filtering is disabl and the system allows all authenticated us from the provide unless they are explicitly blocke Group names mu match exactly as they appear in th claims of the identify provider group. |

| Name | Required | Value Type | Default Value | Description |
| --- | --- | --- | --- | --- |
| `allowed_roles` | No | list of strings (e.g., value [, ...] | [] | Defines a list of external identity provider roles th are authorized tc access the Ocier System through SSO integration. Only users assig to the specified roles in the exter provider can authenticate.<br><br>If this property is empty or you do not specify it, rol based access control is disable for this integratic Role names mus correspond exac to the role claims provided by the identity provider the authenticatic response. |
| `blocked_groups` | No | list of strings (e.g., value [, ...] | [] | Specifies a list of external identity provider groups that are explicitly denied access through this SSO integration. The system blocks us who are member of any specified group in the external identity provider from authenticating, regardless of oth permissions they have. Setting thi property takes precedence over the `allowed_groups` property if a use belongs to both a allowed group ar |

| Name | Required | Value Type | Default Value | Description |
| --- | --- | --- | --- | --- |
| | | | | a blocked group. Group names mu match exactly as they appear in th claims of the identify provider group. |
| `blocked_roles` | No | list of strings (e.g., value [, ...] | [] | Defines a list of external identity provider roles th are explicitly prohibited from accessing the Ocient System through this SSO integration. The system denies access to users assigned to any the specified role overriding any other access permissions. Setting this property takes precedence over the `allowed_roles` property in cases where a user is i both an allowed role and a blocke role. Role names must correspond exactly to the ro claims of the identity provider group. |
| `allow_offline_acce ss` | No | Boolean | `false` | When the `allow_offline_a ss` property is `true`, Ocient requests offline access from the OpenID Connect identity provider including `access_type=off e` and |

| Name | Required | Value Type | Default Value | Description |
| --- | --- | --- | --- | --- |
| | | | | `prompt=consent` the authorizatior URL. |

After all parameters have been retrieved, a database administrator can execute a DDL SQL statement using this syntax.

SQL

```
ALTER DATABASE database
    { SET | ALTER } SSO INTEGRATION sso_protocol <sso_property> [, ...]

<sso_property> ::=
    -- literal or string
    property_name = value |
    -- list
    property_name = [ value [, ...] ] |
    -- map
    property_name = { key = value [, ...] }   # map
```

SQL

```
ALTER DATABASE example_database
    SET SSO INTEGRATION oidc
        issuer = "https://example.com",
        client_id = "xxxxxx",
        default_group = "default",
        additional_scopes = [email, groups, profile, offline_access],
        user_id_claims = [claim1, claim2],
        groups_claim_ids = [claim3],
        groups_claim_mappings = { idp_group1 = ocient_group1, idp_group2 = ocient_g
```

- The user must be a database administrator (or have the “Security Administrator” role for the “system” database).
- The user must be connected to the database.
- Any String key or value can be placed between double quotations (e.g., `default_group` OR `"default_group"` ).
- String values that contain characters other than `([a-zA-z] | [0-9] | '_')` must be placed between double quotations (e.g., `this.is.a.complex-$tring` ⇒ `"this.is.a.complex-$tring"` ).
- The `NULL` value can be used to clear existing configurations of `LIST` or `MAP` properties (e.g., `user_claim_ids = NULL` ).

To remove the connection, execute this SQL statement.

SQL

```
ALTER DATABASE example_database REMOVE SSO INTEGRATION;
```

The OpenID Connect protocol requires TLS for communication between the end user, the database, and the OpenID Provider. A valid TLS key and certificate pair must be configured on the SQL Nodes, which behave as a server during the Authorization Code Flow.

## Set Up Machine-To-Machine SSO Integration

You can use DDL SQL statements to add client credentials for SSO connection to individual databases or to a connectivity pool that operates across SQL Nodes.

These steps set up SSO client credentials on a database, but can also apply to connectivity pools.

### 1 Create an SSO protocol.

Use the **CREATE SSO INTEGRATION** SQL statement to make an SSO integration protocol with your preferred configuration. This configuration must include these properties:

- The `enable_id_token_authentication` SSO property must be set to `true` .
- The `additional_audiences` SSO property must use the URL from the OIDC provider, similar to the `issuer` value.

SQL

```
CREATE SSO INTEGRATION sso_test PROTOCOL oidc
    issuer = "https://accounts.google.com",
    client_id = example_database_app_id,
    default_group = example_database_group,
    enable_id_token_authentication = true,
    additional_audiences = ["https://accounts.google.com"];
```

2 **Assign the SSO protocol.**

Use the **ALTER DATABASE SET SSO INTEGRATION** SQL statement to integrate the SSO protocol into a database. For connectivity pools, use the **ALTER CONNECTIVITY_POOL SET SSO INTEGRATION** SQL statement.

SQL

```
ALTER DATABASE example_database
    SET SSO INTEGRATION sso_test;
```

3 **Connect to your system.**

Use a JDBC connection string that includes the access token value `<access_token>`. This string connects to the local host at port number `4050`, uses the SSO protocol, and with the username `id_token`.

Shell

```
CONNECT TO jdbc:ocient://localhost:4050/system;handshake=SSO;user=id_token;pa
```

## Set Up Cross-Database SSO Integration

Set up authentication using SSO integration across databases. Identify the database that has SSO integration using the `username@database` format, where `username` is the access or identifier token and `database` is the database for the SSO integration. Each SSO

integration has a client identifier `client_id`. You must obtain the access token using the same client identifier used in the SSO integration for authentication.

When you authenticate using SSO integration as a user, the system assigns you to a group defined in the integration. Such users always have groups qualified with the SSO integration of the database. These groups have fully qualified names such as `sso_users@system`, where `sso_users` is the name of the group and `system` is the name of the database. You can use a fully qualified group name from any database. Without the `@database` qualification, the referenced group specifies the current database. To grant cross-database privileges to such groups, you must reference them using their fully qualified names. You can find a list of the groups the current user is a member of by using the **CURRENT_GROUPS** function.

To manage privileges and groups, use the `GRANT`, `REVOKE`, `ALTER GROUP`, and `DROP GROUP` SQL statements. For details about privileges, see **Data Control Language (DCL) Statement Reference**.

### Requirements

- Configure the SSO integration in the source database.
- The SSO user must be a member of a group that has the USE privilege on the target database. If the SSO user is not a member of any groups, the default group for the SSO integration must have the USE privilege on the target database.
- The token (either an access or an identifier token) must be valid for the SSO integration in the source database.

### Create a Cross-Database SSO Integration

These steps guide you through setting up a cross-database SSO integration.

1. Create a default group `sso_users`.

```
SQL

CREATE GROUP sso_users;
```

2 Create the SSO integration `test_sso` in the source database using the `CREATE SSO INTEGRATION` SQL statement. Specify your issuer and client identifier for the `issuer` and `client_id` parameters.

SQL

```
CREATE SSO INTEGRATION test_sso PROTOCOL OIDC
    enable_id_token_authentication = true,
    issuer = 'https://your-idp.com/oidc',
    client_id = 'your_client_id',
    default_group = sso_users,
    additional_scopes = [profile, email, groups, offline_access],
    protocol_version = 'v1',
    groups_claim_ids = [groups];
```

3 Set the SSO integration as the default for the database `source_db`. This step is optional. To set up SSO integration for the `system` database, substitute `source_db` with `system`.

SQL

```
ALTER DATABASE source_db SET SSO INTEGRATION test_sso;
```

4 Grant cross-database privileges to the target database `target_db` for the default group `sso_users`.

SQL

```
GRANT USE ON DATABASE target_db TO GROUP sso_users;
```

5 Connect to the target database `target_db` at the local host with port number `4050` using the JDBC driver with an access token on the source database `access_token@source_db`. Specify a password token.

Text

```
Properties props = new Properties();
props.setProperty("user", "access_token@source_db");
props.setProperty("password", token);
props.setProperty("handshake", "sso");
Connection conn = DriverManager.getConnection("jdbc:ocient://host:4050/target
```

Or, connect using the device flow by using the name of the source database `@source_db`.

Text

```
Properties props = new Properties();
props.setProperty("user", "@source_db");
props.setProperty("handshake", "sso");
props.setProperty("ssoOAuthFlow", "deviceGrant");
Connection conn = DriverManager.getConnection("jdbc:ocient://host:4050/target
```

6 Verify your connection using these queries.

Check the current user using the **CURRENT_USER** function.

SQL

```
SELECT CURRENT_USER();
```

Check the current groups using the CURRENT_GROUPS function.

SQL

```
SELECT CURRENT_GROUPS();
```

Check the current database using the **CURRENT_DATABASE** function.

```sql
SELECT CURRENT_DATABASE();
```

View session information using the `sys.sessions` system catalog table and the identifier of the current session by using the **CURRENT_SESSION_ID** function.

```sql
SELECT * FROM sys.sessions WHERE id = CURRENT_SESSION_ID();
```

You can also retrieve information about the defined groups using the `sys.groups` system catalog table.

## Driver Connection Properties

These tables describe the connection properties you can specify.

### pyocient Parameters

This table lists the DSN parameters that apply to SSO integration. For details, see **Ocient Python Module: pyocient**.

| Parameter | Description | Example |
|---|---|---|
| `handshake` | Authentication method to use for connection. | `sso` |
| `ssoOAuthFlow` | Type of OAuth flow. | `deviceGrant` or `authorizationCode` |
| `identityprovider` | The name of the SSO integration. | `test_sso` |

### JDBC Driver Properties

This table lists the JDBC connection properties that apply to SSO integration. For details, see **CONNECT**.

| Property | Description | Example |
|---|---|---|
| `handshake` | Authentication method to use for connection. | `sso` |

| Property | Description | Example |
| --- | --- | --- |
| `ssoOAuthFlow` | Type of OAuth flow. | `deviceGrant` or `authorizationCode` |
| `identityprovider` | The name of the SSO integration. | `test_sso` |

The `ssoOAuthFlow` values are case-sensitive.

The `authorizationCode` flow requires a web browser on the client machine. The driver opens the sign-in page of the identity provider in the browser, and the browser returns the authorization code to the driver on a local port. The default port is `7050`.

On machines without a web browser, such as headless servers, use the `deviceGrant` flow. The driver displays a verification URL and a user code. Open the URL in a browser on any device and enter the code to complete the sign-in.

## User Access Control and Workload Management with SSO

The database maintains an internal User Access Control model consisting of groups, roles, and service classes. The database relies on group or role membership to determine the privileges of a user or service class. The following integration properties allow administrators to grant SSO users membership to a Database group or role:

- The `groups_claim_ids` and `roles_claim_ids` properties define the token claims that specify the Provider-defined groups or roles of the user.
- The `groups_claim_mappings` and `roles_claim_mappings` properties define mappings between a Provider and Database groups or roles.
- The `additional_scopes` property should include any request scopes needed for the Provider to include the group or role claims in tokens it issues.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Because SSO users can map to multiple groups, when choosing which group to assign creator privileges, the system follows this criteria:

- Filter by authorization using only groups with CREATE privileges on the relevant schema or database.
- When multiple authorized groups exist at different levels, the system uses hierarchy precedence to ensure that privileges are assigned at the most specific scope. The enforced hierarchy is that schema-level group privileges take precedence over database-level group privileges.
- If multiple groups match at the same level, the system selects the group name by using alphabetical order.

For example, if an SSO user belongs to the `analytics_team` group (with CREATE privileges at the database level) and `finance_schema_admins` group (with CREATE privileges at the schema level), and creates a table in the `finance` schema, the system assigns creator privileges to `finance_schema_admins`.

For details about privileges, see **Data Control Language (DCL) Statement Reference**.

Consider an example where the Provider lists all groups the user belongs to in the token claim `"user_groups"` when the application requests the `"example_scope"` scope. In this scenario, the administrator wants to associate the Provider Group `"Example Provider Group"` with the Database Role `"example_database Analyst"`.

SQL

```
ALTER DATABASE example_database
    ALTER SSO INTEGRATION oidc

        /* Tell the Database to request the "profile", "email" and "offline_access"
        additional_scopes = [ profile, email, offline_access ],

        /* Tell the Database to look for the "user_groups" token claim to establish
        roles_claim_ids = [ user_groups ],

        /* Map provider group "Example Provider Group" to database role "example_da
        roles_claim_mappings = { "Example Provider Group" = "example_database Analy
```

By default, the database grants all users membership to the “Public Role” of the database for the current connection. Unlike other default roles, you can grant additional privileges to the “Public Role”.

Additionally, database administrators can revoke access to users with membership to any of the specified Provider groups or roles. To revoke access, execute this statement.

SQL

```
ALTER DATABASE example_database
    ALTER SSO INTEGRATION oidc
        blocked_groups = [ <provider_group_name> [, ...] ],
        blocked_roles  = [ <provider_role_name>  [, ...] ];
```

The user must have the ALTER privilege on all Ocient-defined groups or roles specified by `groups_claim_mappings`, `roles_claim_mappings`, `blocked_groups`, and `blocked_roles`.

## User Claim Identifiers (IDs)

By default, audit trails, including but not limited to system-level log messages, identify users connecting using SSO by the `email` claim. The system resolves the specified claims from both the ID token and the userinfo endpoint response. If the `email` claim is not present in either source, the identifier is `iss` and `sub` claims separated by `::`, for example: `"https://ocient.okta.com::00u5rslndgXm9Ey7y5d7"`.

Some identity providers return a minimal claim set from their userinfo endpoint. For example, Microsoft® Entra ID (formerly Azure AD) v2.0 uses a generic OIDC-compliant userinfo endpoint that does not include commonly used claims such as `preferred_username` or `upn`. These claims might only be present in the ID token. Prior to V29, the system resolved `user_id_claims` only from the userinfo endpoint response, which caused claims available only in the ID token to fail to resolve. Starting in V29, the system checks both sources, so these claims resolve correctly.

To change the FQUN, alter the `user_claim_ids` SSO integration property.

For example, to change the FQUN to a combination of the `first_name` and `last_name` claim values, execute this SQL statement.

SQL

```
ALTER DATABASE example_database
    ALTER SSO INTEGRATION oidc
        user_claim_ids = [first_name, last_name, email];
```

After executing this statement, users are identified with the `<first_name>::<last_name>::<email>` format. (For example: `John::Smith::jsmith@example.com`)

> Updating the `user_claim_ids` property has no effect on users that are already connected to the database.

### System Catalog Tables

Properties that do not contain sensitive data can be viewed using the `sys.oidc_integrations` virtual table. In addition to the configurable properties, a `database_id` column is included in the schema.

To view the configuration for a specific database (if one exists), execute this SQL statement.

SQL

```sql
SELECT *
    FROM sys.databases
    JOIN sys.oidc_integrations
    ON databases.id = oidc_integrations.database_id
    WHERE databases.name = 'example_database';
```

> The user must be a database administrator to view the OpenID Connect properties.

# Database Password Security Settings

Configure password security in Ocient with controls for expiration, lockout, complexity, history, and user account states to meet compliance requirements.

You can manage password security in the OcientAIQ™ Unified Data Platform by using a variety of settings and managing user states.

## Password Security Settings

Ocient® includes password security settings to meet specific security requirements or preferences. Five settings are available to configure your password security.

| Security Setting | Description |
|---|---|
| `password_minimum_length` | The minimum length of passwords. The maximum password length supported by the Ocient System is 32. |
| `password_complexity_level` | An integer value representing the password complexity algorithm. Supported values are:<br>`1` — Level 1. The password must contain at least one upper case character, lower case character, and number.<br>`2` — Level 2. In addition to the requirements specified in level 1, the password must contain at least one non-alphanumeric character. |
| `password_no_repeat_count` | The number of unique passwords that a user must use before they can reuse a password. Even if this setting is set to `0`, when the system determines that the password lifetime has been reached, you must change the password to a unique value. |
| `password_lifetime_days` | The password must be changed after this number of days. After the password is older than this period, the user changes to the `PASSWORD_EXPIRED` state on their next login. |
| `password_invalid_attempt_limit` | The number of login attempts with an invalid password before a user changes to the `DISABLED` state. |

ⓘ Except for the `password_no_repeat_count` setting, a value of 0 for any of these settings means that the system ignores that setting.

## Password Security Setting Hierarchy and Precedence

© 2026 Ocient, Inc

You can set all these settings at the system, database, or group levels. The Ocient System uses the most restrictive value. For example, if `password_minimum_length` is `8` at the system level, `10` at the database level, and `12` at the group level, the system applies the value `12` to the user.

> You can only add a user to a group after you create the user in the system. Upon user creation, `password_minimum_length`, `password_complexity_level`, and `password_no_repeat_count` settings are based only on system- and database-level settings.

## System Catalog Table for Security Settings

The `sys.security_settings` system catalog table shows current security settings. The table contains settings for only databases and groups if any settings are non-zero.

After setting the `password_invalid_attempt_limit` value, you can inspect the value using the `sys.security_settings` system catalog table.

SQL

```
SELECT password_invalid_attempt_limit FROM sys.security_settings;
```

> The `sys.users` system catalog table contains information about users, their current state, and details about their security status, such as the last time the password was updated or the number of failed login attempts.

## Password Recovery

The Ocient System does not enable you to recover a password. If you forget your password, contact the user who has the Security Administrator or Database Administrator role. Users with those roles can set a new password.

## User States

Ocient local users, not SSO-based users, are in one of these states:

- `ENABLED`
- `DISABLED`

- `PASSWORD_EXPIRED`

### `ENABLED` State

Enabled users have normal access privileges to the system. They can connect and execute SQL statements. This state is the default state for all users.

### `DISABLED` State

A disabled user cannot connect to the system, and if they are currently connected, they cannot execute any SQL statements. Users become disabled automatically if they exceed the `password_invalid` number of failed password attempts.

An administrator must set the state of the user to `ENABLED` for the user to resume access.

### `PASSWORD_EXPIRED` State

This state enables a user to log on. However, the only SQL statement they can execute is `ALTER USER <example_user> SET PASSWORD='yyyy'`. The user receives a warning that their password is expired when they authenticate.

Whenever the `password_lifetime_days` number of days has elapsed after the last time the password changed, the system automatically transitions a user to the `PASSWORD_EXPIRED` state on their next login.

You can inspect the last password change timestamp in the `password_updated_at` column in the `sys.users` system catalog table.

### Change User State

To change the state of the user to these different states, use the **ALTER USER** SQL statement.

# Storage Optimization

Reduce storage footprint in an Ocient System using table-level compression, system-level configuration, and data lifecycle management techniques.

The Ocient® System provides several tools and techniques to reduce the storage footprint of your data while maintaining query performance and fault tolerance. This page organizes these techniques into three categories: optimizations you apply when designing tables, optimizations you configure at the system or storage-cluster level, and ongoing practices for managing data lifecycle and storage efficiency over time.

## Table-Level Storage Optimizations

Careful schema design at table creation time yields the largest storage savings. Use these techniques when defining tables:

- Apply column compression — Choose a compression scheme for each column based on its data type and cardinality to reduce on-disk size. The system supports ZSTD compression for strong general-purpose compression, Global Dictionary Compression (GDC) for low-cardinality variable-length columns, and dynamic compression (the default) for automatic lightweight encoding with no configuration required. You can stack GDC and ZSTD for additional savings. For details, see **Table Compression Options** and **Global Dictionary Compression**.
- Use appropriate data types — Select the narrowest data type that fits your data. For example, use `SMALLINT` or `INT` types instead of `BIGINT` when the value range allows. For columns with low cardinality, consider GDC to convert variable-length values to fixed-width integers.
- Leverage complex types to avoid extra tables — Use arrays, tuples, and arrays of tuples to denormalize one-to-many relationships into a single column instead of creating separate child tables. This denormalization eliminates the storage overhead of duplicated foreign keys and additional indexes. For details, see **Array, Tuple, and Matrix Overview**.
- Index selectively — Secondary indexes improve query performance but consume additional storage. Create indexes only on columns that appear frequently in query predicates. Avoid redundant indexes on columns that are already covered by the

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

clustering key or a clustering index. For details about the different index types available and when to use each one, see **Secondary Indexes**.

- Configure the redundancy mode — When creating a table, you can choose between `COPY` and `PARITY` redundancy for each segment part. `PARITY` redundancy uses erasure coding, which consumes less storage than full replication ( `COPY` ) but incurs additional CPU overhead during rebuilds or degraded-state queries. For details, see the `REDUNDANCY` parameter in **Tables**.

## System-Level Storage Configuration

Configure the storage cluster and storage spaces to balance fault tolerance against storage overhead and minimize parity overhead. The system spreads data evenly across all nodes to maximize parallelism and use all available capacity. When a table uses `PARITY` redundancy, the system calculates the storage overhead of erasure coding as `PARITY_WIDTH / (WIDTH - PARITY_WIDTH)`. You can minimize this overhead by keeping `PARITY_WIDTH` as small as your fault-tolerance requirements allow and setting `WIDTH` as large as possible. For example, a 10-node segment group with `PARITY_WIDTH = 2` incurs 25% parity overhead, while `PARITY_WIDTH = 3` on the same width incurs approximately 43% overhead. Any nodes beyond the segment group width are overprovisioned, providing fault tolerance for load operations. You cannot change storage space configurations after creation, so evaluate your needs carefully before creating one. For configuration examples, see **Configure Storage Spaces**.

## Data Lifecycle and Ongoing Storage Management

Use these practices to control storage growth and reclaim space over time:

- Table retention policies — Automatically remove aged data by configuring the `RETENTION POLICY` on tables with a TimeKey® column. The system periodically evaluates each row against the retention period and deletes rows that exceed it. This approach is ideal for time series and streaming workloads where historical data has diminishing value. For details, see **Table Retention Policies**.
- `TRUNCATE TABLE` SQL statement for space reclamation — When removing large volumes of data, use the `TRUNCATE TABLE` SQL statement instead of the `DELETE` statement. Both operations reclaim disk space, but the `DELETE` statement can reclaim storage only for segment groups in which all rows have been removed. The

`TRUNCATE TABLE` statement removes all rows from the table and reclaims all associated storage. For details, see **Remove Records from an Ocient System**.

- Removal of unused indexes — Periodically audit secondary indexes using the system catalog. Dropping an index prevents it from being created in future segments, reducing storage growth over time. Use the `DROP INDEX` SQL statement to remove unneeded indexes. For details, see **Secondary Indexes**.
- Monitoring of storage utilization — Use the `sys.storage_used` system catalog table to inspect per-node, per-table storage consumption. Identifying the largest tables and their compression ratios reveals opportunities for further optimization. For details, see **System Catalog**.

# TimeKeys and Clustering Keys

Use time keys and clustering keys in Ocient to organize table data on disk for fast time-range filtering, efficient pruning, and improved query throughput.

Segment keys define how an Ocient® System partitions data on disk based on particular columns in a database. These keys allow the system to quickly filter rows and skip irrelevant records for queries involving those columns.

For this reason, segment keys are integral tools for optimizing query performance for pivotal columns. Although segment keys are optional, deploying them on every database table in your system is a good practice because they require practically no additional processing or storage resources.

Ocient supports two types of segment keys:

- **TimeKey** — A segment key that partitions data based on a single time-series data column.
- **Clustering Key** — A series of columns that are frequently queried together. The system subdivides these segments on disk for faster reference.

Together, these segment keys form the basis for the Ocient time-cluster storage engine, which subdivides data and metadata for optimal performance.

## Attributes of Segment Keys

### Advantages

Ocient segment keys share these important advantages:

- Improved performance for query filtering and record retrieval.
- Minimal resource demand for storage or input and output (I/O).
- Easy to use. Without sophisticated system knowledge, you can create segment keys with basic data definition language (DDL) statements.

### Limitations

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

There are no significant downsides to using segment keys. However, they have some limitations for deployment:

- You can implement segment keys only upon table creation as part of the initial **CREATE TABLE** statement. You cannot add them later to a table.
- Each database table can support only one key of each type. For faster performance on additional columns, you can also add clustering indexes and other secondary indexes. For details, see **Clustering Indexes** and **Secondary Indexes**.
- Segment keys are restricted to specific column data types.

## TimeKeys

TimeKeys partition data based on a single time-series column in a database table. This column should normally be either a DATE or TIMESTAMP data type.

For optimal performance, you can configure a TimeKey® column with two arguments that comprise a time bucket. The time bucket is a unit of time combined with a number value (e.g., `HOUR, 2` or `DAY, 1`). This value sets the granularity for the partitioning.

In general, this value should match the level of filtering that you expect your queries to request. For example, a database table you expect to query for transactions by minute should probably have a small TimeKey bucket value, such as an hour. If you expect your queries to filter by broader time values, your table can have a TimeKey bucket of one day or larger.

The Ocient System uses the TimeKey and the bucket granularity to partition rows into segments that incorporate a minimum and maximum time value for all rows. For queries that involve time filtering, the TimeKey allows an Ocient System to immediately skip data segments that are outside the query bounds without any I/O processing.

This syntax example creates a single TimeKey column and must be included in the column definition of a `CREATE TABLE` SQL statement. For the full syntax, see **CREATE TABLE**.

SQL

```
column_name [ data_type ] TIME KEY BUCKET (bucket_granularity, bucket_value [, NOIN
```

| Parameter | Type | Description |
| --- | --- | --- |
| `column_name` | string | An identifier for the column. |
| `data_type` | string | Optional.<br>The data type of the column.<br>For the TimeKey column, this column should be DATE or TIMESTAMP type. The TimeKey column can also support INT or BIGINT type, but these data types do not use a `bucket_value` argument. |
| `bucket_granularity` | numeric | The granularity of the TimeKey column, based on the specified TIME type in `bucket_value`. |
| `bucket_value` | string | The TIME type to parse the TimeKey column. Supported values include: `[ DAY, HOUR, MINUTE, SECOND ]`<br>For example, `BUCKET(1, DAY)` sets the time-bucket granularity to a fixed width of one day. |

For DDL examples of tables that use TimeKey columns, see **CREATE TABLE SQL Statement Examples**.

## Time Bucket Indexing

For tables with defined TimeKey columns, the system generates a hidden column named `_TIME_BUCKET` and uses it during clustering to group rows by approximate time ranges, which improves time-range filtering performance.

The `_TIME_BUCKET` column is not visible in a standard `SELECT *` query or data export of the table. To view this column, you must explicitly query it by name.

### Example

This example query specifies the `_TIME_BUCKET` column along with an explicit value (for the purposes of the example, assume the TimeKey column is a TIMESTAMP column).

SQL

```sql
SELECT "_TIME_BUCKET", time_col, metric
FROM my_table
WHERE "_TIME_BUCKET" = TIMESTAMP('2024-01-01 00:00:00');
```

## TimeKey Column Without the Time Bucket

If you want to define a TimeKey that uses bucket semantics but without a `_TIME_BUCKET` column, you can opt out by using the `NOINDEX` keyword.

**Example**

This example of a TimeKey column definition includes the `NOINDEX` keyword to explicitly prevent the time bucket from impacting the system clustering behavior. This option is useful if you want bucketed semantics for certain operations with no impact on storage ordering or index generation.

SQL

```
time_col TIMESTAMP TIME KEY BUCKET(1, DAY, NOINDEX)
```

## Clustering Key

Every table in an Ocient System can support a Clustering Key to speed up query operations on a series of adjacent columns.

The Clustering Key determines how data is ordered into segments on disk. This ordering acts like an index, enabling an Ocient System to quickly locate any relevant rows of the Clustering Key columns.

Every database table should define one Clustering Key on a sequence of frequently queried columns for best results.

Clustering Key columns can be of any fixed-length data type except for `DECIMAL`. Variable-length columns can also support Clustering Keys if they are configured with global dictionary compression. For details, see **Global Dictionary Compression**.

In addition to the Clustering Key, you can also define clustering indexes. Unlike the Clustering Key, clustering indexes do not involve ordering data into segments. They create separate indexes for each specified column set, which boosts performance but requires some additional storage.

This syntax example creates a Clustering Key across multiple columns and must be included in a `CREATE TABLE` SQL statement. For the full syntax, see **CREATE TABLE**.

SQL

```
CLUSTERING KEY key_name (ck_col1, ck_col2 [, ...])
    [, INDEX index_name (idx_col1, idx_col2 [, ...])
    [, INDEX ... ] ]
```

| Parameter | Type | Description |
|---|---|---|
| `key_name` | string | An identifier for the Clustering Key. |
| `ck_col1, ck_col2 [, ...]` | string | A series of specific columns comprising the Clustering Key.<br>Clustering Key columns must not be nullable. Specify `NOT NULL` in the column definition for the respective columns. For details, see **Column Definition**.<br>No limit exists on the number of columns for the Clustering Key. |
| `index_name` | string | Optional.<br>An identifier for a clustering index.<br>You must include the definition of columns that comprise the index using the `idx_col1, idx_col2 [, ...]` parameter. |
| `idx_col1, idx_col2 [, ...]` | string | Optional.<br>A series of specific columns comprising a clustering index.<br>You can apply clustering indexes only to columns included in the Clustering Key. Specify any number of columns in any specified order.<br>You must include the identifier for the index using the `index_name` parameter. |

## Select Clustering Key Columns

You can define a Clustering Key and any additional clustering indexes as arguments of a **CREATE TABLE** SQL statement.

The column ordering of a clustering key is significant. You must specify columns in rank order.

### Table Example

This `CREATE TABLE` SQL statement example shows the definition of a clustering key on columns `(CK1, CK2, CK3)`. The data types of these columns are irrelevant to this

example.

```sql
CREATE TABLE example_table (
    ...,
    CK1 INT,
    CK2 INT,
    CK3 INT,
    ...,
    CLUSTERING KEY ck_example (CK1, CK2, CK3),
);
```

The Clustering Key primes the records for search and filter operations on its columns in descending order of importance. This means the first column `CK1` is the most important of the subset while the third `CK3` is the least important.

To boost performance with a Clustering Key, a query must make references to the columns following this key order.

For a Clustering Key in the `(CK1, CK2, CK3)` pattern, these sequences of query column references are effective:

- `CK1`
- `(CK1,CK2)`
- `(CK1,CK2,CK3)`

### Query Example

This example `SELECT` query follows the key order for its filter operations.

```sql
SELECT * FROM example_table (
WHERE CK1 > 1
    AND CK2 = 0
    AND CK3 < 0;
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

⚠ For a Clustering Key in the `(CK1, CK2, CK3)` pattern, these sequences of query column references are ineffective:

- `(CK1, CK3)`
- `(CK2, CK3)`
- `(CK3, CK2)`

To improve performance on queries that reference columns in these sequences, you can use clustering indexes. For details, see **Adding Clustering Indexes**.

To check the order of column references in a query, you can test a query using an **EXPLAIN PIPELINE** SQL statement. This statement shows the I/O pipeline and how the system references indexes.

For DDL examples of tables that use Clustering Key columns, see **CREATE TABLE SQL Statement Examples**.

## Add Clustering Indexes

A table can only have one Clustering Key, but it can also have any number of clustering indexes to boost performance. Clustering indexes act similarly to the Clustering Key, but they do not order data into segments. Instead, each clustering index creates a separate index for the specified column set, which can impact storage and loading overhead.

Clustering indexes can provide flexibility to your tables, allowing your queries to reference the same columns as your Clustering Key, but in different sequences.

ⓘ You must define clustering keys and clustering indexes when you first create a table. You cannot add them at a later time.

### Example

Define a Clustering Key across the first four columns `(CK1, CK2, CK3, CK4)` in the `example_table` table in this `CREATE TABLE` SQL statement.

The statement also includes two clustering indexes using the `INDEX` definition. The first creates an index for a subset of just two columns `(CK2, CK3)` from the Clustering Key. The second index uses all of the key columns `(CK2, CK4, CK1, CK3)`, but in a different sequence.

© 2026 Ocient, Inc

SQL

```sql
CREATE TABLE example_table (
    CK1 INT NOT NULL,
    CK2 INT NOT NULL,
    CK3 INT NOT NULL,
    CK4 INT NOT NULL,
    COL5 INT NOT NULL,
    CLUSTERING KEY ck_example (CK1, CK2, CK3, CK4),
    INDEX idx_01 (CK2, CK3),
    INDEX idx_02 (CK2, CK4, CK1, CK3)
);
```

ⓘ In the example, `COL5` is not part of the Clustering Key, meaning this column cannot be included in any clustering indexes.

## Permissions

To create TimeKeys and Clustering Keys, you must have the `CREATE` privilege for the current database.

## Observability

You can query these system catalog tables to get information on the effectiveness of your configurations for segment keys and indexes:

- **sys.indexes** — Includes information on the index identifier, type, and other information.
- **sys.index_columns** — Contains information on indexes by their column position.
- **sys.segment_parts** — Contains data on the segment parts associated with each segment key.

For examples of querying segment and index metadata tables, see **Discover Insights From System Catalog Tables**.

# Secondary Indexes

Create and use secondary indexes in Ocient to accelerate selective queries on high-cardinality columns, with syntax, constraints, and performance tips.

Secondary indexes are extremely important for optimizing database queries. When used effectively, indexes allow the database to skip irrelevant records when reading data from storage. On large data sets, this can have a big impact, turning a query that would take minutes to execute into one that finishes in seconds or less.

The tradeoff for using secondary indexes is that they do require additional disk space and loading resources. It is generally a good idea to be strategic about which columns you index. A column is usually a good candidate for an index if you expect it to be frequently referenced in queries, especially for searching and filtering (e.g., in a WHERE or ON clause of a SQL statement).

Creating an index does not trigger the re-indexing of existing segments. Only segments that are generated after the execution of the `CREATE INDEX` statement contain the new index. For that reason, create indexes early on before you load large amounts of data into a table.

You can create indexes on columns containing various data types as long as you meet the requirements in this table. Depending on the data type, the Ocient® System can assign a default index type if you decline to specify one.

## Index Type Requirements and Defaults

This table describes index types that are assigned by default to columns based on the data type. Container data types have special requirements for using indexes.

Unless you explicitly specify an index type, the data type of a column determines a default index type for the system to create.

| Data type | Requirement | Default Index Type (if not specified) |
|---|---|---|
| INT, BIGINT, SMALLINT, FLOAT, DOUBLE, BINARY, DECIMAL, HASH, CHAR, IP / IPV4, | None | `INVERTED` |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Data type | Requirement | Default Index Type (if not specified) |
|---|---|---|
| TIME, TIMESTAMP, DATE, UUID | | |
| VARCHAR | None | `HASH` |
| TUPLE | Inner data types are fixed length or VARCHAR | `HASH` |
| ARRAY | Inner data types are fixed length or VARCHAR.<br>or<br>Inner data type is a tuple containing only fixed-length data types | `HASH` |
| POINT, LINESTRING, POLYGON | None | `SPATIAL` |

You can apply indexes regardless of whether they have GDC compression.

`CREATE INDEX` on tuples currently supports indexing only on individual tuple component columns and not entire tuples.

## Column Requirements for Index Optimization

All index types can speed up queries that involve filter expressions on their designated columns.

An index takes effect when its specified column is queried with a filter expression of either `\<column_name> <op> <literal>` or `<literal> <op> \<column_name>`.

The column and operator must meet one of these requirements.

| Operator | Requirements |
|---|---|
| `=`, `!=`, `>`, `<`, `<=`, `>=`, or `BETWEEN`. | The column must have a non-container data type. |
| `IS NULL` or `IS NOT NULL` | Column must be nullable. |
| `LIKE`, `NOT LIKE`, `=`, `!=`, `SIMILAR TO`, or `NOT SIMILAR TO` | Index type is `NGRAM`. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### Array operator requirements

Additionally, columns with arrays can use indexes if any of these criteria are met.

| Operator or Function | Syntax Example |
| --- | --- |
| The operator is *contains* or *not contains*, i.e., `@>`. | `\<filter_expression> = [NOT] (\<column_name> @> \ <scalar_literal> \| \<array_literal>)` |
| The operator is *is contained* or *not is contained by*, i.e., `<@`. | `\<filter_expression> = [NOT] (\<scalar_literal> \| \<array_literal> \<@ \<column_name>)` |
| The operator is *overlap* or *not overlap*, i.e., `&&`. | `\<filter_expression> = [NOT] (\<column_name> && \ <array_literal>) \| (\<array_literal> && \ <column_name>)` |
| The filter expression uses the `for_some` or `for_all` function. The operator is `=`, `!=`, `>`, `<`, `<=`, or `>=`. | `\<filter_expression> = [NOT] (for_all(\ <column_name>) \<op> \<literal>) \| (for_some(\ <column_name>) \<op> \<literal>)` |

> `BETWEEN` is not supported for `for_some` or `for_all` operators with filter expressions. If the index type is `NGRAM`, the operator can also be `LIKE`, `NOT LIKE`, `SIMILAR TO`, or `NOT SIMILAR TO`.

For syntax information for secondary indexes, see the **CREATE INDEX** reference section.

# Secondary Index Types

Ocient supports four index types alongside the clustering index: `INVERTED`, `HASH`, `NGRAM`, and `SPATIAL`. An index notionally stores a mapping of the column value to the rows that contain that value, and the index type differentiates the format in which the column values are stored and accessed.

For container data types (e.g., arrays and tuples), the index stores the internal elements of the container and is used on predicates that target the internal values. However, a mapping of NULL column values is generally stored for both scalar and container data types, so the index can always be used for `column IS NULL` predicates.

## `INVERTED` Index Type

An `INVERTED` index supports fixed-length column types. The value stored internally in the index is the whole column value, and its storage size is the same as the width of the data

type.

This index allows for exact lookups from a column value to rows and supports strict equality comparisons and range comparisons (e.g., `<`, `>`, `>=`, `\<=`, `BETWEEN`). The index supports EQUALS predicates that perform exact matches on array values (e.g., `CONTAINS`, `OVERLAPS`, and `for_all()` and `for_some()` functions that use `EQUALS` or `IS NULL`), and range comparisons on array values using `for_all()` and `for_some()`.

The system does not use the inverted index for all range comparisons on an index column. Instead, the system determines in advance when it is more performant to use the inverted index for range comparisons. For example, ranges that cover a smaller number of values are more likely to utilize the index.

| Data Type | Function | Supported Operators | Array Operators and Supported Functions |
|---|---|---|---|
| Fixed-length columns<br><br>INT, BIGINT, SMALLINT, FLOAT, DOUBLE, BINARY, DECIMAL, HASH, CHAR, IP / IPV4, TIME, TIMESTAMP, DATE, UUID | Supports range and exact matches.<br><br>The system stores the whole column value (storage is the same as data-type width). | `=`, `!=`, `<`, `>`, `>=`, `<=`, `BETWEEN` | `for_all()`, `for_some()` |

## `HASH` Index Type

The system supports a `HASH` index on variable-length column types, which stores a hash of the indexed column value rather than the full value. You can use `HASH` indexes for exact comparisons, and they support equality and CONTAINS or OVERLAPS filters. The system supports range operators, such as `<` and `>`, and uses sorting logic to determine how `VARCHAR` types compare to each other.

The internal implementation of a `HASH` index requires additional record filtering, making the `HASH` index more computationally intensive than the `INVERTED` index. The additional filtering is attributable to the `HASH` index being a probabilistic index type; because hash collisions are possible, values returned by the index might include false positives that the database must filter internally during query execution to remove invalid results.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Do not use the `HASH` index for variable-length geospatial types, including `LINESTRING` and `POLYGON`. For better results, use the `SPATIAL` index instead.

In most cases, a `HASH` index on a `VARCHAR` column requires less storage than an `NGRAM` index.

| Data Type | Function | Supported Operators | Array Operators and Supported Functions |
|---|---|---|---|
| Variable-length columns VARCHAR, VARBINARY | Supports range and exact matches.<br><br>The system stores a hash of the indexed column. | `=`, `!=`, `<`, `>`, `>=`, `<=`, `BETWEEN` | `@>`, `<@`, `&&`, `for_all()`, `for_some()` |

## `NGRAM` Index Type

The Ocient System supports an `NGRAM` index on variable-length column types. An `NGRAM` index stores substrings of size `n` of the column values. For example, using the default `n_value` size of 3, you can divide the column value `Ocient` into the 3-grams { “Oci”, “cie”, “ien”, “ent” }. The system stores these 3-grams separately in the index and can find them individually.

The `NGRAM` index type helps optimize queries that involve either exact or partial matching filters. When the system uses an N-gram index with a filter string, the database divides the filter value into N-grams in the same manner as the column values, and the system finds each filter N-gram in the index.

`NGRAM` index results are probabilistic because the rows matched by the index can include strings that contain the right N-grams but do not satisfy the filter predicate. As a result, the Ocient query engine must filter column values returned from the index lookup for valid matches. The database uses the index to speed up string similarity where possible, but the index does not support all filters. At a minimum, a filter literal must contain at least one sequence of characters of the `n_value` length that must be present in the resulting column value. For instance, `LIKE` and `SIMILAR TO` expressions that are composed entirely of wildcards cannot use the `NGRAM` index.

For an example of partial matching, see this query on a table that has an `NGRAM(3)` index on the `example_column` column.

SQL

```
SELECT example_column FROM example_table WHERE example_column LIKE 'Ocie%';
```

The filter string `'Ocie%'` results in the filter 3-grams { “Oci”, “cie” } . The database finds these 3-grams in the index and returns any rows that contain those substrings, for example, “Ocient”, “The Ocient database”, and “cieOci”. Of these strings, only “Ocient” satisfies the `LIKE` filter. The database filters out false positives and returns the valid rows.

For an exact matching example, see this query on the same table with the `NGRAM(3)` index.

SQL

```
SELECT example_column FROM example_table WHERE example_column = 'Ocie%';
```

In this case, the database uses similar logic by finding the substrings { “Oci”, “cie”, “ien” } in the index. The database returns only strings that exactly match the input string. While `NGRAM` can significantly increase performance on equality matches, it is generally slower than a `HASH` index.

| Data Type | Function | Supported Operators | Array Operators and Supported Functions |
|---|---|---|---|
| Variable-length columns<br><br>VARCHAR, VARBINARY | Supports exact and partial matches.<br><br>System stores substrings of the `n_value` size of the column values. | `=` , `!=` , `<` , `>` , `>=` , `<=` , `BETWEEN` , `LIKE` , `SIMILAR TO` | `@>` , `<@` , `&&` , `for_all()` , `for_some()` |

## `SPATIAL` Index Type

The `SPATIAL` index type helps expedite queries on geographic data types, including POINT, LINESTRING, and POLYGON values. In a table with a column of these objects, a SPATIAL index finds rows quickly using a geographic literal filter.

This index groups geographic objects together by using a **packed Hilbert R-tree** algorithm. The index allows queries to quickly search through rows by traversing only a subsection of the full data set.

For array types, the `SPATIAL` index is limited to a maximum of one million items per row.

| Data Type | Function | Supported Operators | Array Operators and Supported Functions |
|---|---|---|---|
| Geographic columns that contain `POINT`, `LINESTRING`, or `POLYGON` values. | Supports bounding-box matches that can traverse a Hilbert R-tree structure. | Supports **Geospatial Operators** including: `&&`, `@`, `~=`, `~`.<br>Supports Spatial Relationship functions including:<br>**ST_CONTAINS**<br>**ST_CONTAINSPROPERLY**<br>**ST_COVERS**<br>**ST_COVEREDBY**<br>**ST_CROSSES**<br>**ST_DISJOINT**<br>**ST_DWITHIN**<br>**ST_INTERSECTS**<br>**ST_OVERLAPS**<br>**ST_TOUCHES**<br>**ST_WITHIN** | `for_all()`, `for_some()`<br>Array operators can use the supported **Geospatial Operators**, but not the Spatial Relationship functions. |

## `ZONE_MAP` Index Type

The `ZONE_MAP` index type is a lightweight structure that stores the range of values present in a segment for the indexed column, enabling queries to skip over entire segments with no rows matching a compatible filter.

Unlike other secondary indexes that store values for each row, the system stores `ZONE_MAP` indexes in the metadata of each system segment. The metadata stored for the indexed column includes its minimum and maximum values, as well as any special values (e.g., NULL).

In cases when a compatible filter is outside the bounds of the indexed column, the system can skip processing the segment without performing I/O to fetch raw column data.

To use `ZONE_MAP` indexes most effectively, use them on columns that are also included in a table clustering key because these columns set how the system orders segments on

disk. For details, see **Clustering Key**.

| Data Type | Function | Supported Operators | Array Operators and Supported Functions |
|---|---|---|---|
| Fixed-length columns<br><br>INT, BIGINT, SMALLINT, FLOAT, DOUBLE, BINARY, DECIMAL, HASH, CHAR, IP / IPV4, TIME, TIMESTAMP, DATE, UUID | Supports range and exact matches on a whole segment level.<br><br>The system stores the minimum and maximum values for the column per segment. | `=`, `<`, `>`, `>=`, `<=`, `BETWEEN` | None |

## Create Secondary Indexes Based on Anticipated Queries

These examples demonstrate how to set up indexes based on the expected queries that are frequently executed on the table.

The examples each involve designing indexes to expedite queries on a set of telecommunications data. These queries include:

- Exact matches for approximate location data ( `ipaddress` ).
- Range filtering for data usage ( `totalpackets` ).
- Partial matching for requests to specific URLs ( `httprequesturl` )
- Bounding box matching for exact location data ( `location` )

These examples use a shared table of internet data records, `ip_data`. The columns and their data types in this table are shown here.

SQL

```
starttime (TIMESTAMP)
endtime (TIMESTAMP)
totalpackets (BIGINT)
httphost (CHAR) nullable
httprequesturl (CHAR) nullable
httpstatuscode (SMALLINT) nullable
httpuseragent (CHAR) nullable
destinationport (INT)
sourceport (INT)
ipaddress (IPV4)
ipprotocol (BYTE)
location (POINT)
```

## Optimize an Exact Match Query Using an `INVERTED` Index

This query uses the `ip_data` table to analyze the location of a customer within an approximate time range.

For this use case, a secondary index helps optimize this query template.

SQL

```
SELECT starttime,
       CHAR(ipaddress),
       sourceport,
       destinationport,
       totalpackets
FROM   ip_data
WHERE  starttime BETWEEN '<start_time>' AND '<end_time>'
  AND  ipaddress = '<ip_address>'
LIMIT  10;
```

The crucial column is the `ipaddress`, as it is the crux for the exact matching used in this query.

If data storage is not a problem, this query is ideal for an `INVERTED` index. This index supports exact matching for the IPV4 data type of the `ipaddress` column.

Create an inverted index on this column using this SQL statement.

© 2026 Ocient, Inc

SQL

```
CREATE INDEX destination_ipaddress ON ip_data (ipaddress) USING INVERTED;
```

## Optimize a Range Query Using an `INVERTED` Index

Similar to the exact match query, this query also includes a range filter for the numeric value in the `totalpackets` column.

SQL

```
SELECT starttime,
       CHAR(destinationipaddress),
       sourceport,
       destinationport,
       totalpackets
FROM   ip_data
WHERE  flowstarttime between '<start_time>' AND '<end_time>'
  AND  ipaddress = '<ip_address>'
  AND  totalpackets between 200 and 400
LIMIT 10;
```

An `INVERTED` index is the best choice for this use case. This index supports range filtering for all fixed-length types, including the BIGINT values in the `totalpackets` column.

Create an `INVERTED` index on this column using this SQL statement.

SQL

```
CREATE INDEX totalpackets ON ip_data (totalpackets) USING INVERTED;
```

## Optimize an Exact String Match Using a `HASH` Index

In this case, filter all records where customers accessed the exact web address `ocient.com` .

SQL

```
SELECT starttime,
       CHAR(sourceipaddress),
       CHAR(ipaddress),
       sourceport,
       destinationport,
       httprequesturl
FROM   ip_data
WHERE  starttime between '<start_time>' AND '<end_time>'
  AND  httprequesturl = 'ocient.com'
LIMIT 10;
```

If you expect to filter the `httprequesturl` column only with exact matches, the `HASH` index is usually your best choice. The `HASH` index can greatly speed up exact matching on variable-length data types, and it requires less storage than an `NGRAM` index except in rare edge cases.

SQL

```
CREATE INDEX httprequesturl ON ip_data (httprequesturl) USING HASH;
```

## Optimize a Partial String Match Using `NGRAM` Index

For this use case, filter all records where customers accessed a partial or exact web address. The `LIKE` clause in this query template filters all records for those customers who accessed the Facebook URL.

SQL

```
SELECT starttime,
       CHAR(sourceipaddress),
       CHAR(ipaddress),
       sourceport,
       destinationport,
       httprequesturl
FROM   ip_data
WHERE  starttime between '<start_time>' AND '<end_time>'
  AND  httprequesturl LIKE '%facebook.com%'
LIMIT 10;
```

© 2026 Ocient, Inc

An `NGRAM` index is the best choice for this use case. This index supports partial matching for variable-length data types, including the VARCHAR data type of the `httprequesturl` column.

Create an `NGRAM` index on this column using this SQL statement.

SQL

```
CREATE INDEX httprequesturl ON ip_data (httprequesturl) USING NGRAM(3);
```

In this example, the `NGRAM` index divides the specified column into substrings of three characters, which is the default. This means partial strings such as “Fac”, “ace”, “boo” and other variants are captured in the filter for this query.

You can specify a broader index by setting a higher substring value, such as `NGRAM(4)` or `NGRAM(5)`. Using one of these values would reduce the data storage requirements.

## Optimize a Match Query Using a `SPATIAL` Index

For this use case, filter all records where customers are located in a specific area at a specific time.

This query represents the target area by the bounding box `POLYGON((1 2,1 3,1 4,1 2))`.

SQL

```
SELECT starttime,
       CHAR(sourceipaddress),
       CHAR(ipaddress),
       sourceport,
       destinationport,
       httprequesturl,
       location
FROM   ip_data
WHERE  starttime between '<start_time>' AND '<end_time>'
  AND  ST_CONTAINS(location, POLYGON((1 2,1 3,1 4,1 2)))
LIMIT 10;
```

A `SPATIAL` index is the best choice for this use case because it supports a variety of functions for filtering geospatial data for bounding box areas.

Create a `SPATIAL` index on the `location` column by using this SQL statement.

```sql
CREATE INDEX location ON ip_data (location) USING SPATIAL;
```

## Optimize a Range Query Using a `ZONE_MAP` Index

This query analyzes network traffic originating from a specific range of IP addresses.

```sql
SELECT starttime,
       CHAR(ipaddress),
       sourceport,
       destinationport,
       totalpackets
FROM   ip_data
WHERE  ipaddress BETWEEN '192.168.0.0' AND '192.168.255.255'
LIMIT  10;
```

If you load the data so the system clusters it by IP address (e.g., sorted by `ipaddress`), a `ZONE_MAP` index is highly efficient for this query. This index allows the system to quickly identify and scan only the segments that contain IP addresses within the requested range, skipping all others.

Create a `ZONE_MAP` index on this column using this SQL statement.

```sql
CREATE INDEX starttime_idx ON ip_data (ipaddress) USING ZONE_MAP;
```

# Table Compression Options

Configure Ocient table compression options, including dictionary, run-length, and delta encodings, to reduce storage costs and accelerate scan performance.

The Ocient® System provides a range of options for compressing tables to reduce storage requirements for your data. Compression can be a major component of query optimization when used effectively by reducing I/O requirements and potentially allowing more system space for indexes.

## Ocient Compression Key Concepts

Table columns in Ocient can support these compression options:

- **Global Dictionary Compression (GDC)**
- **Zstandard Compression (ZSTD)**
- **Dynamic Compression**

Ocient System compression adheres to these key concepts:

- By default, the Ocient dynamic compression scheme can determine whether to apply compression on each column if it is statistically advantageous. Sometimes, you might want to use another compression scheme like ZSTD or completely disable compression.
- You can specify custom compression schemes on individual columns through data definition language (DDL) commands, either using a `CREATE TABLE` or `ALTER TABLE` SQL statement.
- GDC can stack onto other compression schemes.

### General Compression Matrix

This table shows the best compression scheme for different column data types. The suggested best compression schemes consider the column data type and cardinality, but other factors can influence which data compression makes sense.

The default compression in the table shows the compression scheme that the database applies if you do not specify an option. This default compression balances performance

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

and compression.

| Data Type | Default Compression | Best Compression |
|---|---|---|
| Fixed-length | `COMPRESSION DYNAMIC` | `COMPRESSION ZSTD` |
| Variable-length and low cardinality | `COMPRESSION NONE` | `COMPRESSION GDC` and `COMPRESSION ZSTD` |
| Variable-length and high cardinality | `COMPRESSION NONE` | `COMPRESSION ZSTD` |
| Arrays | `COMPRESSION NONE` | `COMPRESSION ZSTD` |
| Arrays of variable-length types and low cardinality | `COMPRESSION NONE` | `COMPRESSION GDC` and `COMPRESSION ZSTD` |
| Tuples | Compression depends on each tuple index data type. | The database treats each tuple index position as its own column value and can support its own compression scheme. Fixed-length values default to `COMPRESSION DYNAMIC`, while variable-length values default to `COMPRESSION NONE`.<br>For best performance, apply rules for each tuple index based on the data-type rules outlined in this table.<br>For example:<br>`my_tuple TUPLE<<INT, VARCHAR(255) COMPRESSION GDC(1) COMPRESSION ZSTD, VARCHAR(255)>>`<br>This example defines a tuple column with GDC and ZSTD compression only for the first inner `VARCHAR` value. |

For details about the advantages and disadvantages of each compression scheme, see the `compression_scheme` description in **Column Constraint**.

For details about the compression syntax, see **CREATE TABLE**.

## Global Dictionary Compression

Column parameter: `COMPRESSION GDC`

GDC uses a dictionary encoder to map variable-length column data. Instead of storing the variable length data directly on disk, GDC substitutes each unique string with a corresponding unique integer.

This compression scheme can significantly reduce overall storage requirements for low-cardinality columns with a few distinct values while boosting performance for various operations.

GDC supports an optional `compression_value` argument that specifies how many unique values to use.

### Advantages

- Reduced disk usage — Variable-length data, such as strings or container types, can experience massive storage reduction.
- Improved query performance — By mapping each row to an integer, variable-length rows no longer require a full traversal for selective I/O operations, which improves performance in some queries.
- Faster Joins — Join comparisons have improved performance from using GDC integers instead of the variable-length data.
- Variable-Length Cluster Keys — Variable-length columns can use a clustering key index for improved performance.
- Stackable — Columns can use GDC in tandem with other compression schemes.

### Disadvantages

- Increased complexity — You must know the rough cardinality of your data to size the GDC configuration properly.
- Load complexity — GDC compression adds some overhead to loading data into the Ocient System.
- Not suitable for high-cardinality data — GDC performance decreases as the data cardinality increases.
- Cannot apply retroactively — Unlike other compression options, you must set GDC as part of the initial `CREATE TABLE` SQL statement. You cannot apply it later to the table.

For details, see **Global Dictionary Compression**.

SQL

```
column_name [data_type] COMPRESSION GDC [ (compression_value) ]
```

For details about adding GDC compression to a table schema, see **CREATE TABLE**.

## Zstandard Compression

Column parameter: `COMPRESSION ZSTD`

ZSTD uses the ZSTD library to apply a fast and lossless compression algorithm to any column type, including fixed and variable-length scalars, arrays, and tuples on a per-component basis. In addition, ZSTD works on columns where the database first compresses variable-length data by GDC and then compresses the resulting integral type on disk.

This compression scheme can affect performance by requiring additional processing. Therefore, this compression scheme is usually good for less-frequently accessed columns or columns paired with an index.

ZSTD supports these optional values:

- `COMPRESSION_LEVEL` — This value signifies how much compression the data receives. The default value is `0`. The full range of values is from `-7` (low compression) to `15` (high compression). The database requires less memory when this value is lower, whereas it requires more memory and processing resources when the value is larger.
- `DICTIONARY_SIZE` — This value is the dictionary size that you specify as a positive integer. The value signifies the size of the shared compression dictionary in bytes. The default value is `32768` (32 KB). The full range of values ranges from 4096 (4 KB) to `1048576` (1 MB). This value denotes the amount of memory consumed during segment generation. In general, larger values provide better compression but use more memory.

> The default values for `COMPRESSION_LEVEL` and `DICTIONARY_SIZE` are sufficient for most cases.

### Advantages

- Reduced disk storage — Dramatically decreases disk space usage.
- Flexible — You can apply this compression scheme after table creation using an **ALTER TABLE** SQL statement.

### Disadvantages

- Performance loss — ZSTD does require some extra CPU resources, which means that it can impact query performance.
- Memory usage — ZSTD can demand significant memory usage when many columns use it for parallel query workloads.

```
SQL

column_name [data_type] COMPRESSION ZSTD
   [COMPRESSION_LEVEL = level_value, DICTIONARY_SIZE = size_value]
```

For details about adding ZSTD compression to a table schema, see **CREATE TABLE**.

## Dynamic Compression

Column parameter: `COMPRESSION DYNAMIC`

By default, Ocient tables use dynamic compression to reduce storage space requirements automatically. This method employs a variety of compression schemes on columns based on their data type and a statistical determination of what kinds of compression would be advantageous.

- For fixed-length data, block-size units (typically 4 KB) can receive various compression schemes, including run-length encoding and delta-delta encoding.
- For variable-length data (VARCHAR and VARBINARY), the database compresses data row-by-row, with values individually compressed using LZ4 compression. This method produces a good compression ratio for large values. However, small or medium-sized values have negligible compression rates.

### Advantages

- Ease of use — The Ocient System determines the compression.
- Flexibility — You can apply this compression scheme after table creation using an **ALTER TABLE** SQL statement.

### Disadvantages

- Secondary option — Dynamic compression is designed for balance, but it is generally not as effective at compression as ZSTD.
- Performance loss — This compression scheme has a small performance impact, but is not as costly as ZSTD.

```SQL
column_name [data_type] COMPRESSION DYNAMIC
```

For details about adding dynamic compression to a table definition, see **CREATE TABLE**.

For examples of tables that use compression, see **CREATE TABLE SQL Statement Examples**.

# Global Dictionary Compression

Use global dictionary compression in Ocient to reduce storage costs on repeated string values and accelerate query performance with dictionary-based filters.

Global Dictionary Compression (GDC) is a feature of the database that compresses variable length column data using a dictionary encoder. Instead of storing the variable length data directly on disk, GDC seamlessly substitutes an integer that corresponds to each unique string.

## Advantages of GDC

1. **Reduced disk usage** — A string like `"GDC is really cool!"` takes up 19 raw bytes. With GDC, it takes at most four bytes. This benefit is multiplied by the number of rows in the table and, when applied to arrays, can lead to a dramatic reduction in required storage.
2. **Fixed-width** — Variable length column data can be more difficult to perform selective input or output (I/O). It is much faster for Ocient® to read the 100th element in a list of integers by offsetting 100 times the fixed width of the integer. With variable-length types, a full traversal is required, counting how many elements are passed until the 100th is found. This can improve performance in some queries.
3. **Faster Joins** — When joining on a GDC column, equality comparisons can be performed on the GDC integers instead of the variable-length data. This can improve performance in some queries.
4. **Allows Variable-Length Cluster Keys** — As of version 19.0 of the Ocient System, GDC is the only method by which a variable-length column can be used as a cluster key index.

## Disadvantages of GDC

1. **Increased complexity** — GDC does add some configuration complexity. It requires a user to know the rough cardinality of their data to size the GDC number of bytes and adds system configuration options.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

2. **Load complexity** — GDC compression adds some overhead to loading data into the Ocient System.
3. **Not suitable for high-cardinality data** — If the variable length column has higher cardinality than this, it should not be stored using GDC.

# GDC Syntax

To create a GDC column, add the `COMPRESSION GDC(int)` parameter after the column type specifier when creating a column, where `int` is one of 1, 2, or 4. The integer specifies the number of bytes to be used for the integer keys stored on the disk. This also corresponds to the maximum number of unique keys to be stored in a particular column.

| GDC(int) | Maximum Number of Unique Values |
|---|---|
| GDC(1) | 256 |
| GDC(2) | 65,536 |
| GDC(4) | 4,294,967,296 |

> There is a *soft* limit of 1,000,000 keys even on four-byte integer GDC columns. Contact Ocient Support to evaluate your criteria for changing the limit and to understand the impact of raising limits.

## Apply GDC to a Column

To enable GDC on a column, the keyword is applied in the `CREATE TABLE` or `ALTER TABLE ADD COLUMN` statement. An example of GDC on a `VARCHAR` column:

```
{column_name} VARCHAR(255) COMPRESSION GDC(2)
```

When you apply GDC to one column, the Ocient System creates a view instead of a table from the full column definition.

## Reuse an Existing GDC Map

A user can also specify that a column should share GDC space with another column–possibly even a column of a different table. This would be useful if the same data is used in multiple columns and it is often joined in queries. Use `COMPRESSION GDC EXISTING schema.table.column_name` as shown here:

```
{column_name} VARCHAR(255) GDC EXISTING {schema.table.column_name}
```

### GDC on Array Columns

For arrays of variable-length data, GDC operates on the individual elements of the array. Specify compression after the overall array type:

```
{column_name} VARCHAR(255)[] COMPRESSION GDC(2)
```

### GDC on Tuple Columns

Elements of tuple columns can be compressed with GDC. Specify compression on the specific type to be compressed:

```
{column_name} tuple<int, VARCHAR(255) COMPRESSION GDC(2)>
```

## GDC in the System Catalog

You can use the system catalog to inspect the number of keys used by different columns and the maximum count on each.

**Example Query:**

SQL

```sql
SELECT
  t.id as table_id,
  t.name as table_name,
  c.id as column_id,
  c.name as column_name,
  g.compressed_size,
  g.current_count,
  g.max_count
FROM sys.tables t
INNER JOIN sys.global_map_table_info g
  ON t.id = g.table_id
INNER JOIN sys.columns c
  ON c.id = g.column_id;
```

## Truncation

When a table with GDC is partially truncated, *GDC key mappings for removed rows are not removed*. This can result in stale mappings. The only way to remove unwanted mappings is to drop the column and recreate it.

## GDC Column Representation in the System Catalog

To the end user, a table with GDC columns looks like any other table. However, when creating a table with GDC columns, the table configuration is different in system catalog tables. Instead of a table named `schema.tablename`, GDC tables leverage a built-in view.

This view and several pieces of metadata will be created in the system catalog:

1. A view named `schema.tablename` is added in `sys.views`. This view is the representation of the user of the GDC table, and it automatically converts the GDC keys to the loaded variable-length data. This is the table that the user interacts with for querying data, making alterations, and granting or revoking access.
2. For each GDC column in the table, a table named `syslookup.schema_tablename_columnname` is added in `sys.tables`. These tables store the mappings from strings to integers for each column. These tables should be interacted with only rarely.
3. A table called `sysgdc.schema_tablename` is added in `sys.tables`. This is the table that is stored to disk, including all the non-GDC columns and the integers for each GDC column. This table should be interacted with only rarely.

## GDC Columns and Loading into the Database

GDC stores key mappings in a Raft consensus log that is maintained by all nodes operating with the Admin role. These mappings are created as the data is loaded, and used in queries to fetch the correct variable length data for the stored integers. Mappings can also be created by certain queries if the key does not already exist.

Because the Admin roles are responsible for maintaining the GDC key mappings, there must be a consensus of Admin roles available on the system in order to load new data that includes GDC columns.

# Table Retention Policies

Ocient table retention policies automate data lifecycle by deleting aged records based on time-key columns, reducing manual maintenance and optimizing storage.

The Ocient® System supports table retention policies, an automated way to manage and delete data after a specific time. These policies help maintain storage efficiency on a schedule.

Using DDL SQL statements, you can modify individual tables to specify their own retention policies for how long the system should keep data before automatic removal.

## Requirements

To add table retention policies, you must have `ALTER` and `DELETE` privileges for the system and the specific table.

In addition, a database table must meet these conditions to support retention policies:

- Have a designated TimeKey® column (For details, see **TimeKeys and Clustering Keys**)
- Be a user-created table or system-persistent table. You cannot edit virtual system tables.

## Table Retention Properties

Table retention properties define the specific parameters that control how long data remains in a table before being automatically deleted. These properties determine both the duration of retention and the granularity at which the system evaluates data for removal, ensuring that retention policies operate consistently and predictably. By configuring these properties, you can fine-tune how the system balances data availability with storage efficiency.

### Table Retention and TimeKey

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Retention policies of a table are directly linked to the column defined as the TimeKey of the table. For each row in the table, the TimeKey column represents its age, which the system evaluates to determine whether to retain or delete the row. Table retention policies cannot function properly if the TimeKey column does not represent the age of each row.

Additionally, the TimeKey bucket value also represents the frequency of evaluating the age of each row in the table. For example, a table with a TimeKey bucket of `1 HOUR` and a retention period of `1 DAY` would evaluate each row every hour to determine if it is more than one day old.

Based on the TimeKey bucket frequency for culling older records, the system can potentially retain a row for slightly longer than the set period of a retention policy, up to a maximum retention time of the sum of the retention period and the TimeKey bucket.

> The table retention policy also deletes older rows of any dependent global dictionary compression tables defined on columns of the original table.

## Table Retention Tasks

The system deletes older records as a distributed task, which is visible in the **sys.tasks** and **sys.subtasks** catalog tables. Additionally, each table retention policy creates a scheduled process, which is visible in the **sys.tkt_table_info** system catalog table. For details, see **Distributed Tasks**.

## Retention and Workload Management

Retention policies execute periodically to delete data in two separate phases: a truncate operation and a delete operation.

The truncate operation interfaces directly with the storage layer of the system and is not affected by any workload management configuration.

In contrast, the delete operation runs as a `DELETE` SQL statement and uses a designated `Retention Policy` service class for retention policies. This service class is a built-in class that administrative users can edit. All table retention policies use the same service class.

## Default Retention Policies

A subset of persistent system tables has table retention policies set by default. All retention policies in the system, including those set by default, are visible in the **System Catalog**.

You can also view a retention policy for an individual table by executing an **EXPORT TABLE** statement.

## Add Retention Policies to Tables

You can add table retention policies using a `CREATE TABLE` or `ALTER TABLE` SQL statement.

Table retention policies are optional for all user-defined tables. If a table lacks a retention policy, the default behavior is to retain data in perpetuity.

Retention policies follow this syntax as part of either a **CREATE TABLE option** or an **ALTER TABLE** statement.

SQL

```
RETENTION POLICY AGE retention_granularity retention_value
```

| Parameter | Type | Description |
|---|---|---|
| `retention_granularity` | numeric | A number that represents the amount of time before the system deletes data in the table. You must pair this number with a specific time type, represented by the `retention_value`. |
| `retention_value` | string | The unit of time that represents how long the table retains data. Supported values are: `[ WEEK, DAY, HOUR, MINUTE, SECOND, MILLISECOND ]`<br><br>For example, `1 DAY` schedules the table retention to a granularity of one day. |

### Example

This example creates a retention policy that keeps rows only if they are less than one day old, as specified by the last line, `RETENTION POLICY AGE 1 DAY`. The retention policy depends on the `created_at` column because it is the TimeKey column. The TimeKey

bucket value `(1, HOUR)` determines how frequently the system checks for any rows to remove.

SQL

```
CREATE TABLE IF NOT EXISTS "transact_data" (
    "created_at" TIMESTAMP TIME KEY BUCKET(1, HOUR) NOT NULL,
    "user_id" INT NOT NULL DEFAULT 0,
    "sell_id" BIGINT NOT NULL,
    "purchase_amount" BIGINT NOT NULL DEFAULT 0,
    "buyer_name" VARCHAR(1048576),
    CLUSTERING KEY "primary_index" ("sell_id", "user_id")
) RETENTION POLICY AGE 1 DAY;
```

### Tables

### CREATE TABLE SQL Statement Examples

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# CREATE TABLE SQL Statement Examples

Examples of the Ocient CREATE TABLE SQL statement showing time-keyed tables, clustering keys, secondary indexes, partitioning, and supported data types.

Tables in the OcientAIQ™ Unified Data Platform contain various configuration options that can impact performance, reduce storage requirements, or provide extra data safeguards.

As some table configuration options cannot be added after data is already loaded, it is important that you take the time to design `CREATE TABLE` SQL statements with forethought for the queries that you expect to execute frequently. This topic provides examples of `CREATE TABLE` SQL statements designed for different use cases and describes the configuration choices.

For syntax and parameter information, see **CREATE TABLE**.

## Create a Table with All Data Types

This example creates a table with all supported data types in Ocient®. The intent of this example is to show the required formatting for different data type values, which is shown as the `DEFAULT` value for each column.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```sql
CREATE TABLE data_type_example (
    col_bigint BIGINT NOT NULL DEFAULT 9876543210,
    col_binary BINARY(3) NOT NULL DEFAULT '0xabcdef',
    col_boolean BOOL NOT NULL DEFAULT TRUE,
    col_char CHAR(4) NOT NULL DEFAULT 'val',
    col_date DATE NOT NULL DEFAULT '2000-01-01',
    col_decimal DECIMAL(18,4) NOT NULL DEFAULT 123.45,
    col_double DOUBLE NOT NULL DEFAULT 3.141592,
    col_float FLOAT NOT NULL DEFAULT 2.718,
    col_int INT NOT NULL DEFAULT 123456789,
    col_int_array INT[] NOT NULL DEFAULT 'INT[0,1,2,3]',
    col_ipv4 IPV4 NOT NULL DEFAULT '127.0.0.1',
    col_ip IP NOT NULL DEFAULT '0123:4567:89ab:cdef:0123:4567:89ab:cdef',
    col_smallint SMALLINT NOT NULL DEFAULT 32767,
    col_matrix MATRIX[2][3] NOT NULL DEFAULT '{ {0, 0, 0}, {0, 0, 0} }',
    col_point POINT NOT NULL DEFAULT 'POINT(0 0)',
    col_linestring LINESTRING NOT NULL DEFAULT 'LINESTRING(0 0, 1 1)',
    col_polygon POLYGON NOT NULL DEFAULT 'POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))',
    col_time TIME NOT NULL DEFAULT '12:34:56.012345678',
    col_timestamp TIMESTAMP NOT NULL DEFAULT '2000-01-02 12:34:45',
    col_tinyint TINYINT NOT NULL DEFAULT 127,
    col_tuple TUPLE<<INT, INT>> NOT NULL DEFAULT 'tuple<<INT,INT>>(0,0)',
    col_array_of_tuples TUPLE<<INT, INT>>[] NOT NULL DEFAULT 'TUPLE<<INT,INT>>[tupl
    col_uuid UUID NOT NULL DEFAULT '01234567-89ab-cdef-1357-0123456789ab',
    col_varbinary VARBINARY NOT NULL DEFAULT '0xaabbccddeeff',
    col_varchar VARCHAR NOT NULL DEFAULT 'This is a variable length string'
);
```

## Create a Table for Real-Time Analysis

This example assumes you plan to ingest large quantities of time series data for rapid querying. The most important columns that you plan to reference in queries frequently include:

- `created_at` — A granular timestamp column that represents the primary time reference in the table.
- `user_id` — An integer column to identify each unique user.
- `sell_id` — An integer column representing each transaction by a user.

© 2026 Ocient, Inc

SQL

```
CREATE TABLE IF NOT EXISTS "transact_data" (
    "created_at" TIMESTAMP TIME KEY BUCKET(1, HOUR) NOT NULL,
    "user_id" BIGINT NOT NULL DEFAULT 0,
    "sell_id" BIGINT NOT NULL,
    "purchase_amount" DOUBLE NOT NULL DEFAULT 0,
    "buyer_name" VARCHAR,
    CLUSTERING KEY "ck" ("sell_id", "user_id")
);

CREATE INDEX "purchase_idx" ON "transact_data" ("purchase_amount");
CREATE INDEX "buyer_idx" ON "transact_data" ("buyer_name")
    USING NGRAM(4);
```

This example table makes use of these Ocient System configurations.

| Column Name | Configuration Description |
|---|---|
| `created_at` | This column is the table TimeKey®, which means that the database indexes for filter optimization.<br>The example configures the TimeKey to partition segments by every hour, `(1, HOUR)`, which is the approximate time granularity you expect to use in your query filters. |
| `user_id`, `sell_id` | The example table identifies these two columns as the table Clustering Key. The database pairs these two columns for quick reference, such as filtering one column for row values of the other. |
| `purchase_amount` | The `CREATE INDEX` SQL statement adds a secondary index to this column. As a `BIGINT` data type, the `purchase_amount` column defaults to the `INVERTED` index. |
| `buyer_name` | This `CREATE INDEX` SQL statement adds a secondary index to this column. As a `VARCHAR` column, the `buyer_name` column normally defaults to a `HASH` index, but this example specifies it should be an `NGRAM` index of width `4` instead. |

For details about using the TimeKey and Clustering Key functionality, see **TimeKeys and Clustering Keys**.

For details about other index types, see **Secondary Indexes**.

# Create a Table for Geospatial Data

This example assumes you plan to ingest geospatial data linked to time series data using OcientGeo™. The most important columns that you plan to reference frequently in queries include:

- `route_time` — A granular timestamp column that represents the primary time reference in the table.
- `start_point`, `end_point` — The geospatial point values for the start and destination locations.
- `trip_id` — An integer column to identify each unique trip.
- `vehicle_id` — An integer column that represents each vehicle.

SQL

```
CREATE TABLE "trip_details" (
    "route_time" TIMESTAMP TIME KEY BUCKET(14, DAY) NOT NULL,
    "start_point" POINT NULL,
    "end_point" POINT NOT NULL DEFAULT 'POINT(0 0)',
    "route_path" LINESTRING NOT NULL
        DEFAULT 'LINESTRING(0 0, 1 1)',
    "route_area" POLYGON NOT NULL
        DEFAULT 'POLYGON((0 0, 0 1, 1 1, 1 0, 0 0))',
    "trip_id" BIGINT NOT NULL,
    "vehicle_id" BIGINT NOT NULL,
    CLUSTERING KEY "ck" ("trip_id", "vehicle_id")
);

CREATE INDEX "start_idx" on "trip_details" ("start_point")
    USING SPATIAL;
CREATE INDEX "end_idx" on "trip_details" ("end_point")
    USING SPATIAL;
```

This example table makes use of these Ocient System configurations.

| Column Name | Configuration Description |
|---|---|
| `route_time` | This column is the table TimeKey, which means that the database indexes for filter optimization.<br>The example configures the TimeKey to partition segments by every two weeks `(14, DAY)`, which is the approximate time granularity that you expect to use in your query filters. |

| Column Name | Configuration Description |
| --- | --- |
| `trip_id`, `vehicle_id` | The example table identifies these two columns as the table Clustering Key. The database pairs these two columns for quick reference, such as filtering one column for row values of the other. |
| `end_point`, `route_path`, `route_area` | These columns have `POINT`, `LINESTRING`, and `POLYGON` data types, respectively.<br>Each of these geospatial columns includes default values in its respective format. |
| `start_point`, `end_point` | The `CREATE INDEX` SQL statements for both of these columns assign `SPATIAL` indexes for quicker reference. This index is the default type for any column with a geospatial data type. |

For details about OcientGeo functionality, see **Geospatial Functions**.

## Create a Table With Compression Options

This example table includes multiple compression options to ensure minimal storage for specific columns and extra performance.

> Most data types, except arrays, have `COMPRESSION DYNAMIC` applied by default.

SQL

```
CREATE TABLE "call_records" (
    "utc_timestamp" TIMESTAMP TIME KEY BUCKET(1, DAY) NOT NULL,
    "sectorid" VARCHAR
        COMPRESSION ZSTD,
    "address" VARCHAR
        COMPRESSION NONE,
    "call_type" VARCHAR
        COMPRESSION ZSTD
        COMPRESSION GDC(4),
    "access_information" VARCHAR(500)
        COMPRESSION GDC(4),
    "file_name" VARCHAR
        COMPRESSION ZSTD compression_level = 3,
        dictionary_size = 1048576,
    CLUSTERING KEY "ck" ("call_type", "access_information")
);
```

This example table makes use of these Ocient System configurations.

| Column name | Configuration Description |
|---|---|
| `address` | This column explicitly removes compression by specifying `COMPRESSION NONE` in the `CREATE TABLE` SQL statement. |
| `call_type`, `access_information` | These columns have `VARCHAR` data types configured with Global Dictionary Compression (GDC).<br>This compression scheme maps the variable-length type rows to integers. Among other benefits, this compression allows both columns to support a Clustering Key for faster querying.<br>The `call_type` column stacks multiple compression schemes by including both GDC and ZSTD compression to provide additional storage reduction. |
| `file_name` | This column uses ZSTD compression with extra options. The `compression_level` is set for `3`, meaning the column data is slightly more compressed than the default `0`. The dictionary_size is set for the maximum value, `1048576`, which means greater compression but higher memory demand. |

For details about Ocient compression schemes, see **Table Compression Options**.

## Create a Table for Various Container Types

This example table includes complex container data types, including a two-dimensional array, a tuple with variable-length values, and a tuple with various data types.

SQL

```
CREATE TABLE "container_data" (
    "utc_timestamp" TIMESTAMP TIME KEY BUCKET(1, DAY) NOT NULL,
    "user_id" BIGINT NOT NULL DEFAULT 0,
    "sell_id" BIGINT NOT NULL DEFAULT 0,
    "point_array_col" POINT[],
    "array_col" VARCHAR[] COMPRESSION GDC(4),
    "2D_array_col" INT[][],
    "tuple_col1" TUPLE<<
        VARCHAR(255),
        VARCHAR(500)
        >>,
    "tuple_col2" TUPLE<<
        INT,
        INT[],
        VARCHAR COMPRESSION GDC(1) COMPRESSION ZSTD,
        VARCHAR
        >>,
    "matrix_col" MATRIX[5][10],
    CLUSTERING INDEX "ck" ("user_id", "sell_id")
);

CREATE INDEX "point_idx" on "container_data" ("point_array_col")
    USING SPATIAL;
CREATE INDEX "tuple_idx" on "container_data" ("tuple_col1"[1])
    USING HASH;
CREATE INDEX "tuple_idx2" on "container_data" ("tuple_col2"[2])
    USING INVERTED;
```

This example table makes use of these Ocient System configurations.

| Column name | Configuration Description |
|---|---|
| `point_array_col` | This column is an array of `POINT` values that is indexed using a `SPATIAL` index type as specified by the `CREATE INDEX` SQL statement. |
| `tuple_col1` | This tuple column contains two variable-length values.<br>Each object in the tuple can support its own compression scheme and index.<br>The `CREATE INDEX` SQL statement assigns a `HASH` index to the first value ( `VARCHAR(255)` ). |
| `tuple_col2` | This tuple column contains various data types. Each object in the tuple can support its own compression scheme and index.<br>The two `VARCHAR` objects in the tuple column each have their own unique |

| Column name | Configuration Description |
| --- | --- |
| | compression scheme.<br>The `CREATE INDEX` SQL statement assigns an `INVERTED` index to the second tuple object, the integer array `INT[]`. |

For details about Ocient container types, see **Array, Tuple, and Matrix Overview**.

## Create a Table With a Retention Policy

This example creates a retention policy that keeps rows only if they are less than one day old, as specified by the last line, `RETENTION POLICY AGE 1 DAY`. The retention policy depends on the `created_at` column because it is the TimeKey column. The TimeKey bucket value `(1, HOUR)` determines how frequently the system checks for any rows to remove.

SQL

```
CREATE TABLE IF NOT EXISTS "transact_data" (
    "created_at" TIMESTAMP TIME KEY BUCKET(1, HOUR) NOT NULL,
    "user_id" INT NOT NULL DEFAULT 0,
    "sell_id" BIGINT NOT NULL,
    "purchase_amount" BIGINT NOT NULL DEFAULT 0,
    "buyer_name" VARCHAR(1048576),
    CLUSTERING KEY "primary_index" ("sell_id", "user_id")
) RETENTION POLICY AGE 1 DAY;
```

For details about configuring table retention, see **Table Retention Policies**.

# Manage Distributed Tasks

Distributed tasks run in the background of the Ocient System to keep it running smoothly, with persistent state in the global metadata storage cluster.

Distributed tasks are processes that run in the background of the Ocient® System to keep the system running smoothly and efficiently. These tasks provide persistent storage of task information in the global metadata storage cluster of the Ocient System, allowing tasks to be tracked and retried until completion. For details about storage and related concepts, see **Core Elements of an Ocient System**.

The distributed task infrastructure is completely generic. The system instantiates tasks from factories using generic arguments and establishes communication using interfaces to abstract the business logic in whatever specific protocol is doing the actual work. Tasks must remain unchanged when duplicated and can be restarted on a new node by the infrastructure at any time. Tasks can also be structured recursively, with a parent task comprising several subtasks, which can also have subtasks, and so on.

Distributed tasks provide persistence across outages. To do this, the task infrastructure detects when the node running a task, or the task owner, has become unavailable and moves the task elsewhere. The administrator owner manages node unavailability. This owner is a node in the administrator cluster responsible for monitoring the status of a task and reassigning the task owner when needed. This pairing of administrator and task owners provides load balancing across the administration cluster by removing the need for every task owner to communicate with the administrator owner.

## Task Types

The Ocient System has different task types, such as:

- Data pipeline loading
- Rebuild segments
- Check for disk corruption by verifying segments

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- Rebalance data across storage clusters and nodes

For data pipeline loading, see **Load Data**.

For details about rebuilding segments, checking the disk, and rebalancing data, see **Distributed Tasks**.

## Task Characteristics

The characteristics of a task are a factory, serialized arguments, a location type, and a location identifier:

- Factory — A task class implementation that the Ocient System instantiates generically and executes the actual work of the task.
- Arguments — The inputs to a task the Ocient System stores generically as a string. These inputs can contain anything the task needs, e.g., flags modifying execution modes, identifiers on which to run, etc.
- Location type — The nature of the set of nodes where the task can run. This location can be any node in the system, any node in a specific cluster, or a specific node.
- Location identifier — The specific location entity when the task location type is a cluster or node.

Tasks have optional pre- and post-condition checks and must implement an asynchronous execute method. You can also override the cancel and status poll methods.

## Task Execution

Execute tasks using a pair of nodes: administrator and task owners. The administrator owner must be an active node in the metadata storage cluster. This node is responsible for starting and monitoring the task. The task owner can be any node that meets the location constraints specified by the task creator and executes the actual task. With the exception of subtasks, the Ocient System assigns both owners upon task creation, chosen randomly to balance the load.

© 2026 Ocient, Inc

To see the disposition of tasks in the system, see the `sys.subtasks` system catalog table. For details, see **sys.subtasks**.

### Administrator Owner

The administration owner manages and monitors all steps in the life cycle of their own tasks. After the Ocient System adds a task to the cluster state and assigns an administrator owner, the Administrator Node sends a message to the task owner to submit or poll the current task status. After the task has started successfully, the administrator owner periodically polls the task owner for the task status, updating it in the cluster state as needed.

When a task completes, the administrator owner sets its state to a terminal status and no longer polls or interacts with the task. The Ocient System retains historical tasks in the cluster state until a configurable limit is reached to prevent the state from growing unboundedly.

### Task Owner

The task owner maintains an in-memory map of running tasks by the identifier in the health protocol. The Ocient System pools tasks for execution status as needed. When the Ocient System receives a poll task request from an administrator owner, a task owner checks for the existence of the task, starting it if necessary and returning the current status.

The Ocient System starts a task by instantiating a task object using the factory type and then executing its pre-condition check, method, and post-condition check. If at any point the system encounters a failure, the system stops execution.

When a task completes, the task owner stores the results in memory until it receives an indication from the administrator owner that it is safe to remove the results.

## Handle Outages

### Administrator Owner

An important responsibility of the administrator owner is to detect and handle task owner outages. If a poll fails for any reason, the administrator owner reassigns the

owner in the cluster state and starts the task in the new location. Tasks must remain unchanged when duplicated and resume where they stopped when restarted.

If an administrator owner fails, the administrator leader detects the connectivity change and reassigns the administrator owner. The new administrator owner begins polling the task owner when it receives the update, so the ownership change should not interfere with task execution.

### Task Owner

Generally, the task owner does not need to handle outages. However, in extreme situations, e.g., network splits, an administrator owner might not be able to communicate with its task owner and orphan a task. To prevent orphaned tasks from running in multiple locations in the system, the task owner times out and cancels a running task if it has not heard from the administrator owner in multiple poll cycles.

## Subtasks

When you execute a task using a SQL statement, the task performs the operation by executing one or multiple subtasks. Thus, when you query the system catalog tables for subtasks, you must look for numerous subtasks and their individual progress rather than just one task.

You can also execute tasks as a series of subtasks, that run sequentially, in parallel, or some combination of the two. The series comprises a parent task with a number of child tasks. Each child task has a specified ordering. The Ocient System executes tasks with the same ordering in parallel. And, the system executes groups of child tasks in sequence according to ascending order. The Ocient System assigns an administrator owner when the child task should begin running. The system executes parent tasks directly on the administrator owner. These tasks are only responsible for watching the status of their running child tasks and starting the next child tasks when applicable. Parent tasks complete after all their children tasks complete.

To see the disposition of subtasks in the system, you can query the `sys.subtasks` system catalog table. For details, see **sys.subtasks**.

## Task Cancellation

A client can request to gracefully cancel a task by setting an `is_canceled` flag on the task object. The administrator owner evaluates this state on its next poll cycle and notifies the task owner that the task should be canceled. The exact mechanism by which the running task is canceled varies by type, as some tasks might need to communicate with other protocols to stop execution.

Canceling a parent task causes all of its subtasks to be canceled. A subtask cannot be canceled individually.

If the task is successfully canceled, execution ends with a `CANCELLED` status and reverts back to the administrator owner and Raft state using the normal success or failure paths.

For example, cancel the task named `my_task`.

SQL

```
CANCEL TASK 'my_task';
```

For the full syntax, see **CANCEL TASK**.

# Remove Records from an Ocient System

Remove records from an Ocient System safely using DELETE statements, retention policies, and segment-level operations while preserving data consistency.

Ocient® supports multiple options for removing records from a database. Here, you can find the different methods for removing data along with their advantages and drawbacks to help you determine the method that best fits your needs.

> ⚠ All options for removing data are destructive and cannot be undone after execution. Therefore, be cautious when removing any Ocient records from your database.

## Required Permissions

To remove data, a user must have the `DELETE` privilege for the specified table. For details on privileges, see the **Data Control Language (DCL) Statement Reference**.

## Remove Records Using DELETE

The `DELETE` SQL statement removes specific individual rows from a table based on the `WHERE` filter clause.

Unlike `TRUNCATE`, the `DELETE` statement does not restore the disk space of deleted rows without further system operations. In general, `DELETE` is a good option when removing small row sets, not entire tables.

If a `DELETE` statement has no `WHERE` filter, it removes all rows in the table.

The `DELETE` statement can support concurrent operations to remove rows on the same table, which might impact performance.

For details about the `DELETE` statement, see **DELETE FROM TABLE**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### Remove Data Using DELETE with a Filter

In this example, the `DELETE` statement removes all rows from the `products` table with a value less than 1 in the `rating` column.

SQL

```
DELETE FROM products WHERE rating < 1;
```

### Remove Data Using Joined Tables

You can use `DELETE` with a `JOIN` statement to help filter rows for removal based on a condition that applies to the second table.

> The statement removes rows only from the first table and not the second joined table.

This example deletes rows after performing a `JOIN` operation on the geospatial values in two tables:

- `point_table` contains a column of geospatial point values.
- `us_state_table` contains columns of all abbreviated U.S. state names and polygon values representing their boundaries.

The `JOIN` operation uses the **ST_INTERSECTS** function to evaluate if each point value in `point_table` is contained within any of the polygon values in the `us_state_table`.

The example deletes any rows in `point_table` that are within the boundaries of Texas, abbreviated as `'TX'`.

SQL

```
DELETE FROM point_table p
    JOIN us_state_table s ON ST_INTERSECTS(s.polygon_wkt, p.point_wkt)
WHERE s.state LIKE 'TX';
```

## Data Durability Considerations

© 2026 Ocient, Inc

To remove data, the data must be queryable in the system. For example, streaming data systems might experience a delay before rows can be deleted while they are in progress of the loading process to become fully durable.

In most cases, data should be loaded and queryable within a matter of seconds.

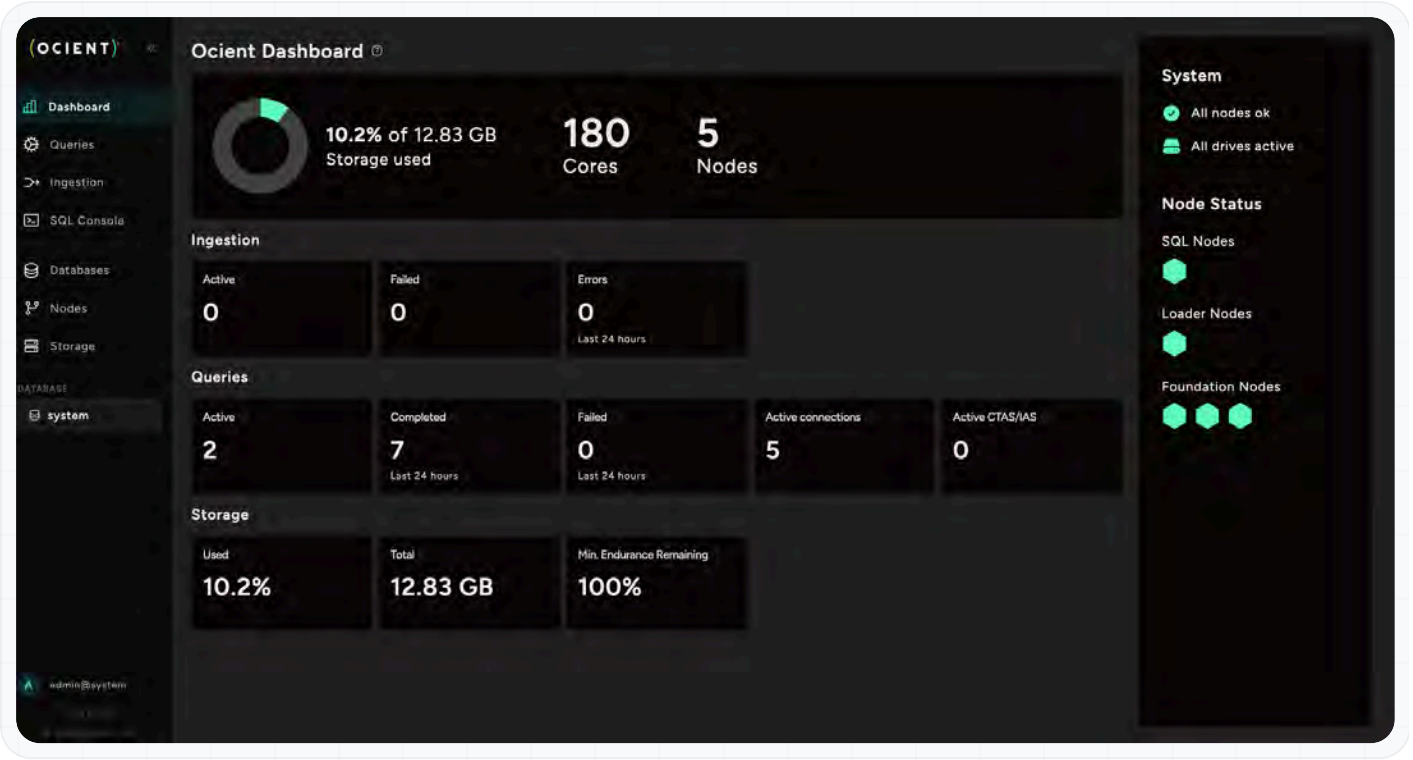
# Ocient Management UI Features

Overview of the Ocient Management UI for monitoring, managing, and interacting with your Ocient System through a web-based interface.

The Ocient® Management UI is a web-based interface for monitoring and managing your Ocient System. The Management UI provides at-a-glance visibility into system health, query activity, data ingestion, storage utilization, and node status. This UI also includes an interactive SQL Console and a guided Pipeline Builder for creating data pipelines without writing DDL statements.

The Management UI is accessible from any supported web browser by navigating to the URL of your Ocient System SQL Node. For connection details, access control, and endpoint configuration, see **Ocient Management UI Configuration**.



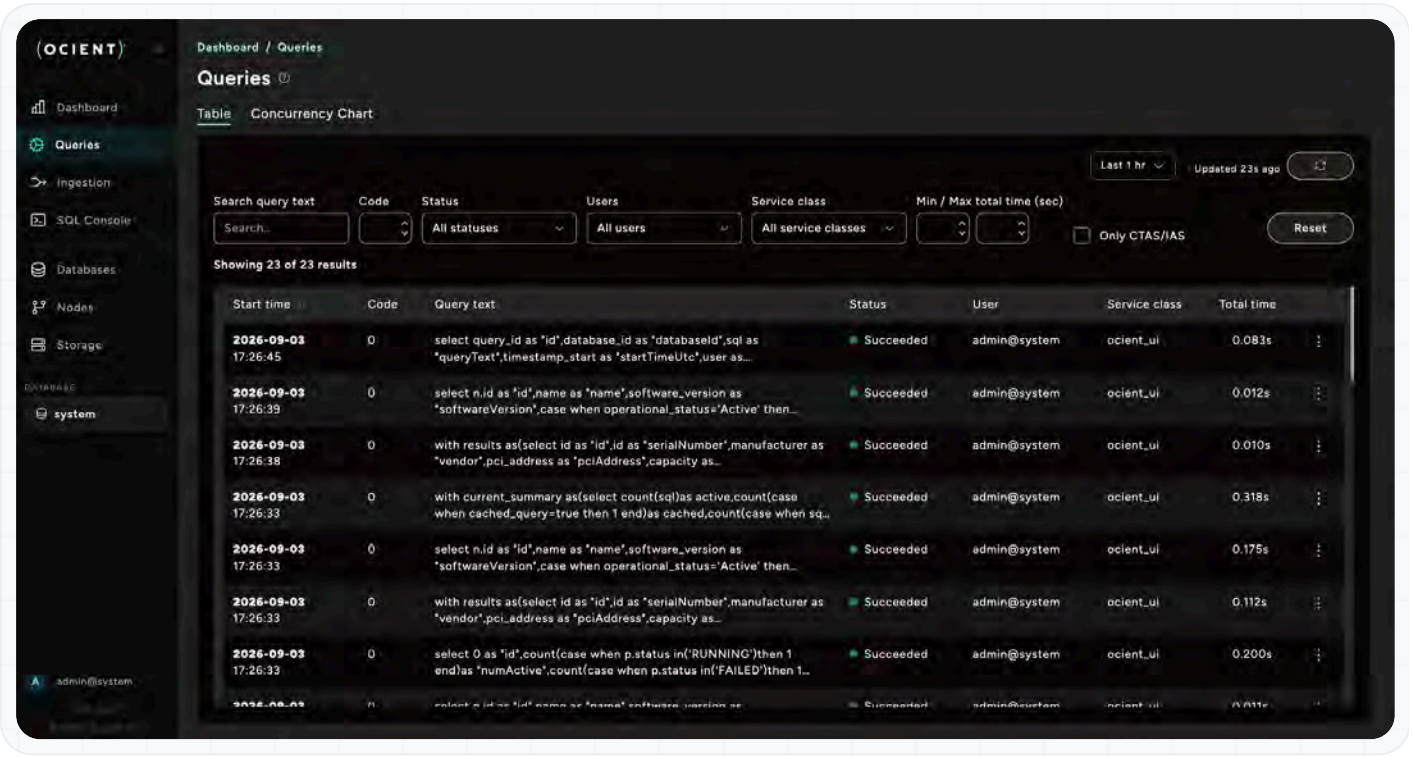
The Management UI includes a persistent database switcher in the sidebar, which lets you change your active database connection without logging out.

## Dashboard

The Dashboard page is the landing page of the Management UI. This page provides a high-level summary of your Ocient System, including storage utilization, total cores, node count, and overall system health.

Metric cards summarize query activity, ingestion status, storage utilization, and node health across the system.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential



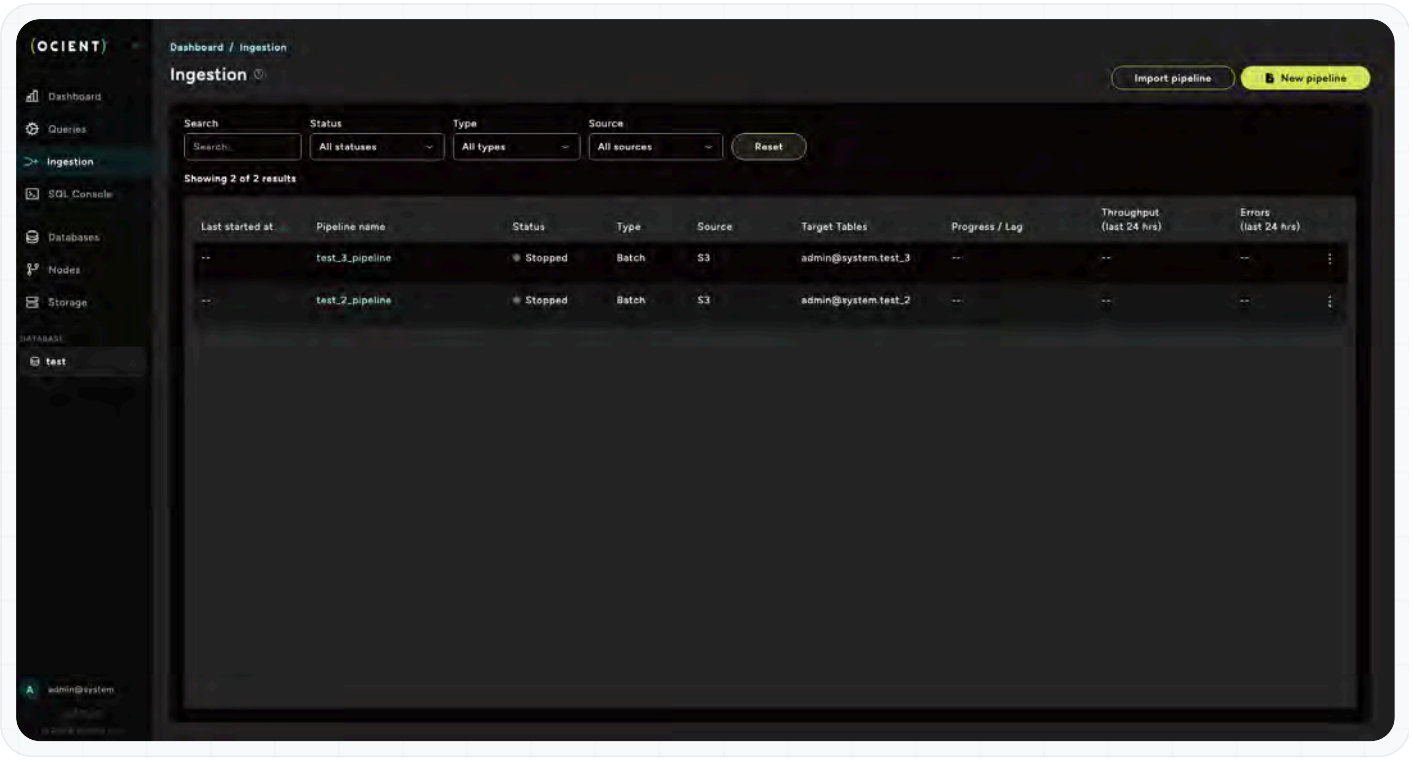
# Queries

The Queries page displays a detailed log of all queries executed against the system, including queries that the Management UI itself runs to populate its pages. You can filter queries by text, status, user, service class, and execution time. Each entry shows the start time, query text, return code, status, user, service class, and total execution time. A **Concurrency Chart** view is available for visualizing query concurrency over time. Select a query to view its full details.

For details about query execution and performance, see **Query Performance Tuning**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

# Ingestion



The Ingestion page lists all data pipelines configured on the system. You can search and filter pipelines by status, type, and source. Each pipeline entry displays its start time, name, status, type, source, target tables, progress or lag, throughput, and error count over the last 24 hours.

Select **Import pipeline** to import an existing pipeline definition, or select **New pipeline** to open the **Pipeline Builder** and create a new pipeline. To create or import a pipeline, you must select a user database. These options are not available when you connect to the `system` database.

If you have an unsaved draft pipeline from the Pipeline Builder, a draft card appears at the top of the pipeline list. From the draft card action menu, you can click **Resume** to resume the draft in the Pipeline Builder, click **Download** to download the pipeline definition, or click **Delete** to delete the draft. While a draft exists, you cannot create, alter, or duplicate a pipeline because you must resume or delete the draft first. Draft pipelines are user-specific; each user can have one draft at a time.

For details about data pipelines, see **Load Data**. To learn how to monitor pipeline health and progress, see **Monitor Data Pipelines**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

# Pipeline Builder

The Pipeline Builder is a guided workflow for creating new data pipelines using the Management UI. To open the Pipeline Builder, select **New pipeline** on the **Ingestion** page. You must select a user database in the sidebar.

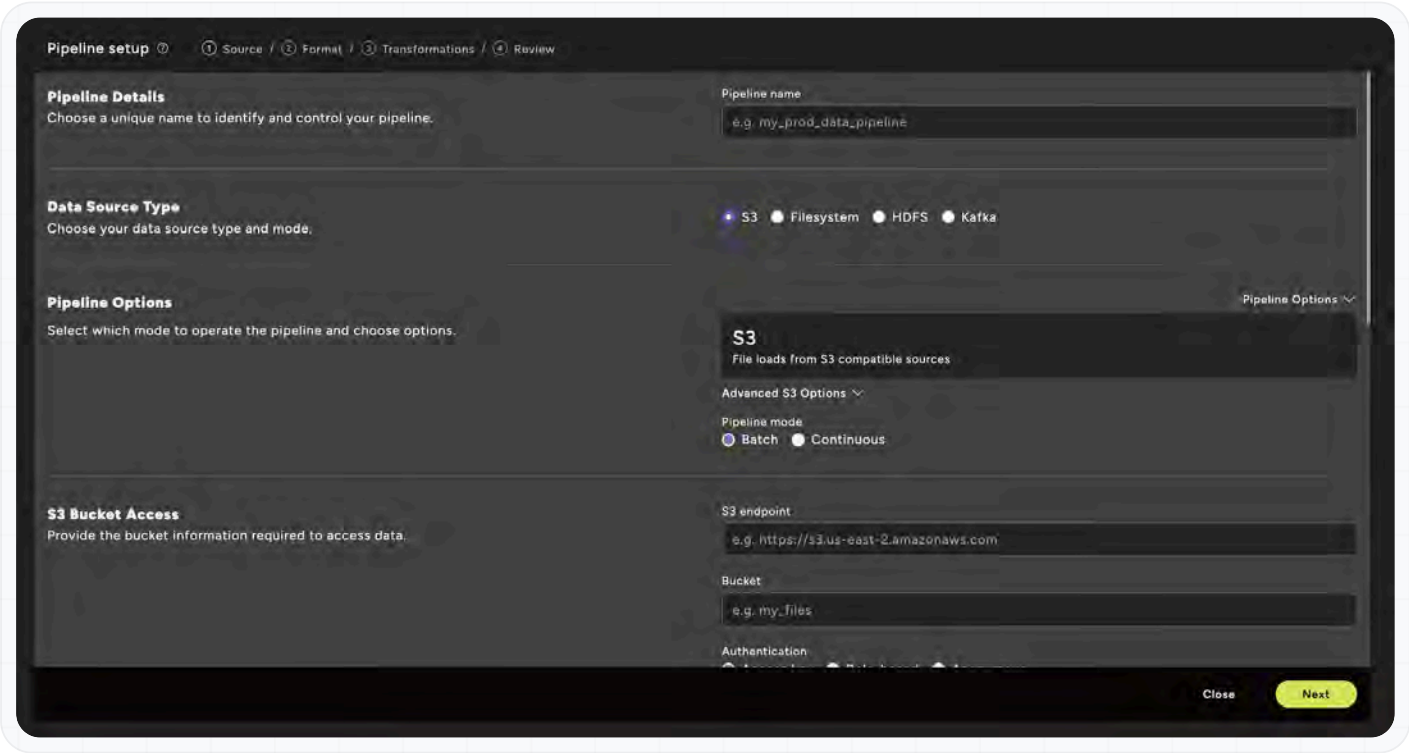
> The Pipeline Builder is not available when you connect to the `system` database.

The Pipeline Builder opens in a new browser tab, so you can continue using the rest of the Management UI while you build the pipeline.

The Pipeline Builder automatically saves your progress to browser local storage as you work. If you close the browser or navigate away before completing the pipeline, the Pipeline Builder preserves your draft. When you return to the **Ingestion** page, you can resume the draft from where you stopped. Each user can have one draft pipeline at a time.

The Pipeline Builder follows a multi-step process:

1. **Source** — Configure the pipeline name, select a data source type (Amazon® Web Services℠ (AWS℠) S3, Filesystem, Apache® Hadoop® Distributed File System



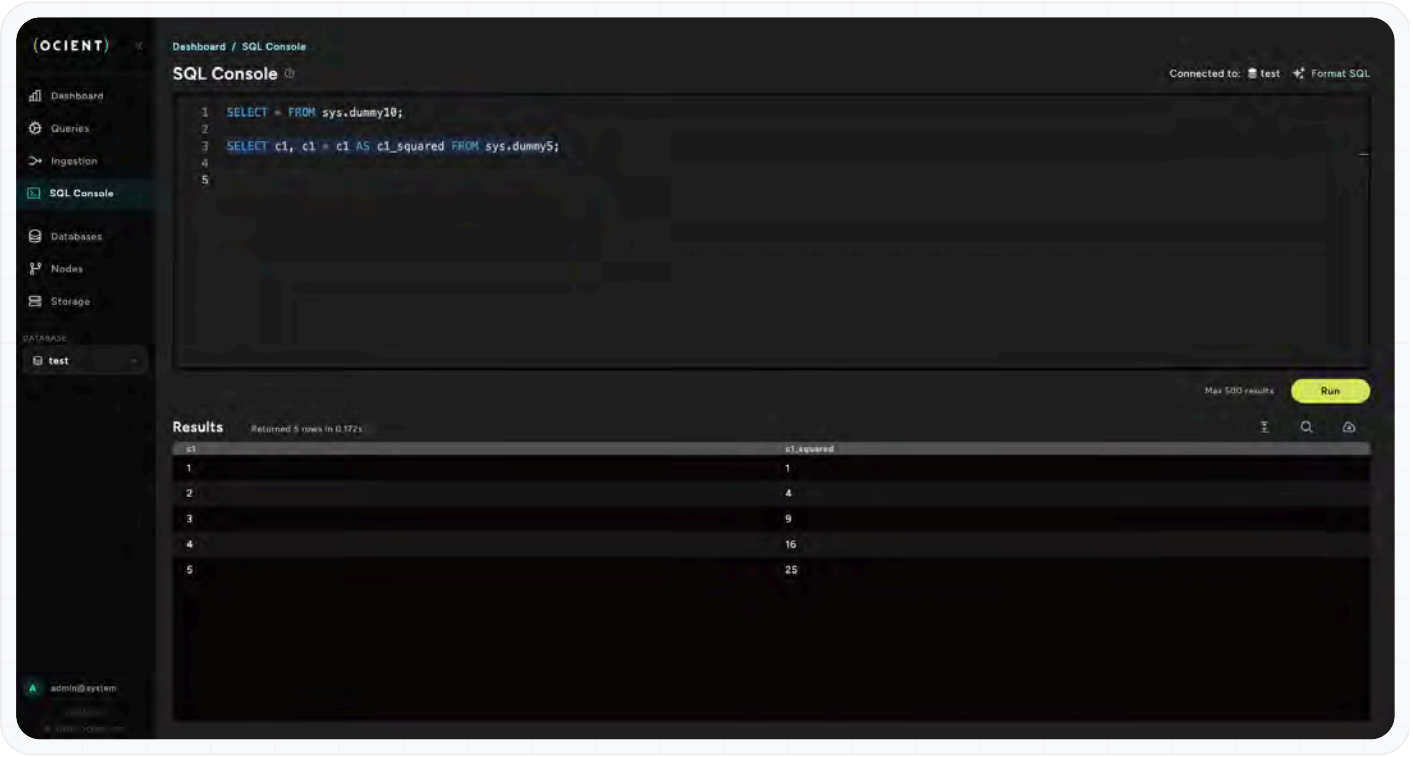
(HDFS), or Apache® Kafka®), choose a pipeline mode (Batch or Continuous), and provide connection details.

2. **Format** — Define the data format and parsing options.
3. **Transformations** — Apply any data transformations before loading.
4. **Review** — Review the pipeline configuration before creation.

For tutorials on loading data from specific sources, see:

- **Data Pipeline Load of CSV Data from S3**
- **Data Pipeline Load of JSON Data from Kafka**
- **Data Pipeline Load of Parquet Data from S3**

For details about data formats and transformations, see **Data Formats for Data Pipelines** and **Transform Data in Data Pipelines**.

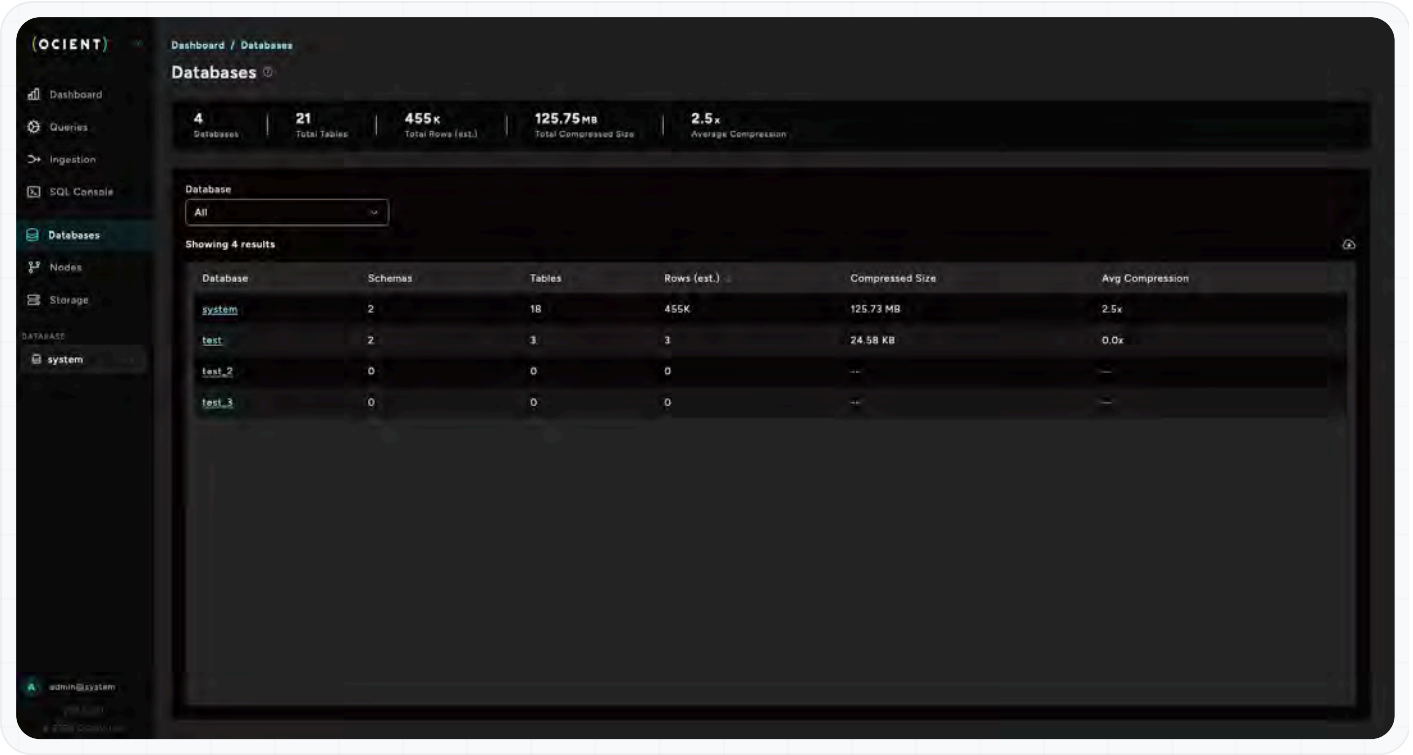


# SQL Console

The SQL Console provides an interactive query editor directly in the browser. You can write and execute SQL statements against the connected database, with results displayed below the editor. The console displays the active database connection and includes a **Format SQL** option to format your queries. The console caps results at a configurable maximum row count.

When the editor contains multiple semicolon-delimited SQL statements, the SQL Console executes only the statement where your cursor is positioned. The console highlights the selected statement to confirm which query executes. To execute a specific statement, place your cursor anywhere within the statement and select **Run** or press **Ctrl+Enter** (Windows®/Linux®) or **Cmd+Enter** (macOS®). If the editor is not focused when you select **Run**, the console executes all statements in the editor.

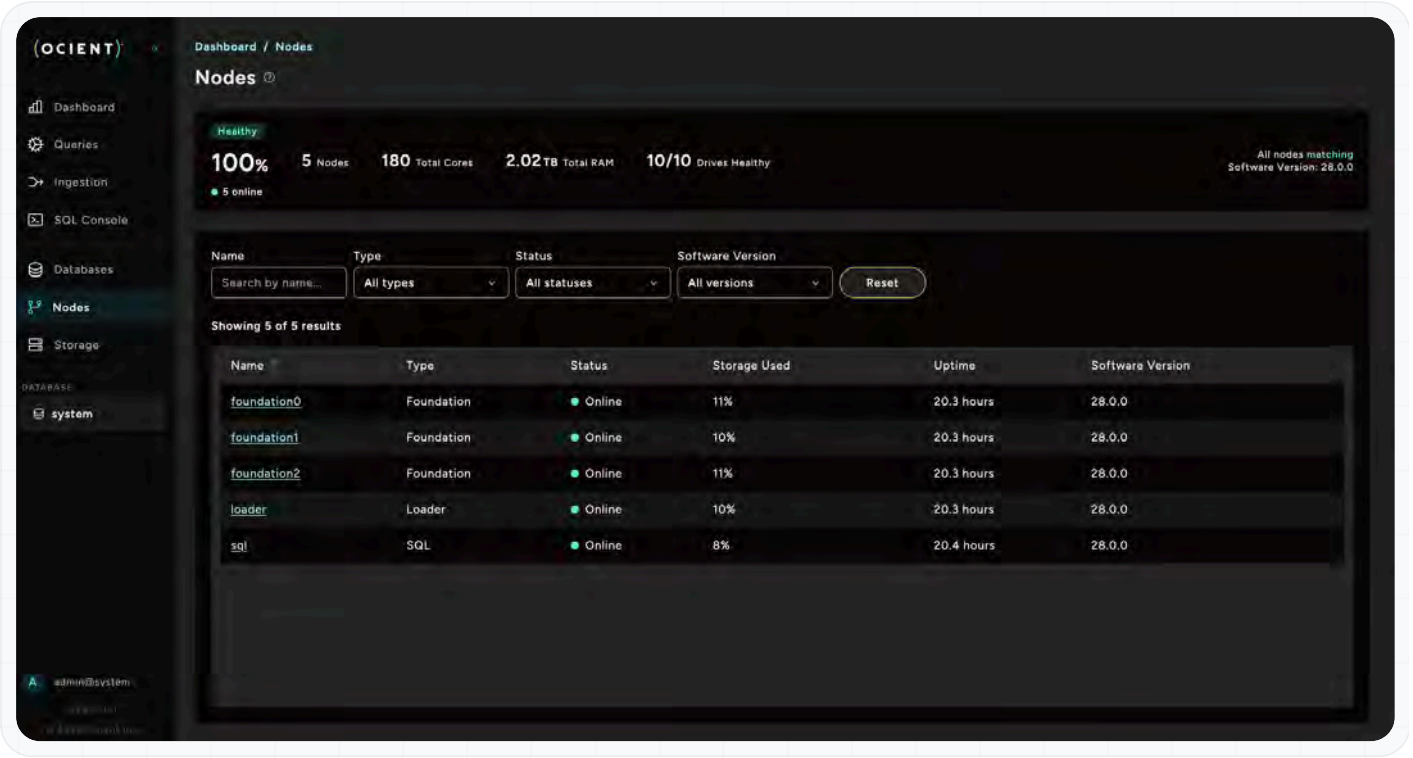
For an introduction to querying Ocient, see **Quick Start Querying**.



# Databases

The Databases page provides an overview of all databases on the system. Summary statistics show total databases, tables, estimated rows, compressed size, and average compression. The table lists each database with its schema count, table count, estimated row count, compressed size, and average compression ratio. Use the dropdown to filter by a specific database.

Select a database to view its schemas, select a schema to view its tables, views, and models, and select a table to view its columns, indexes, constraints, and details. You can also view details for a selected schema or database.



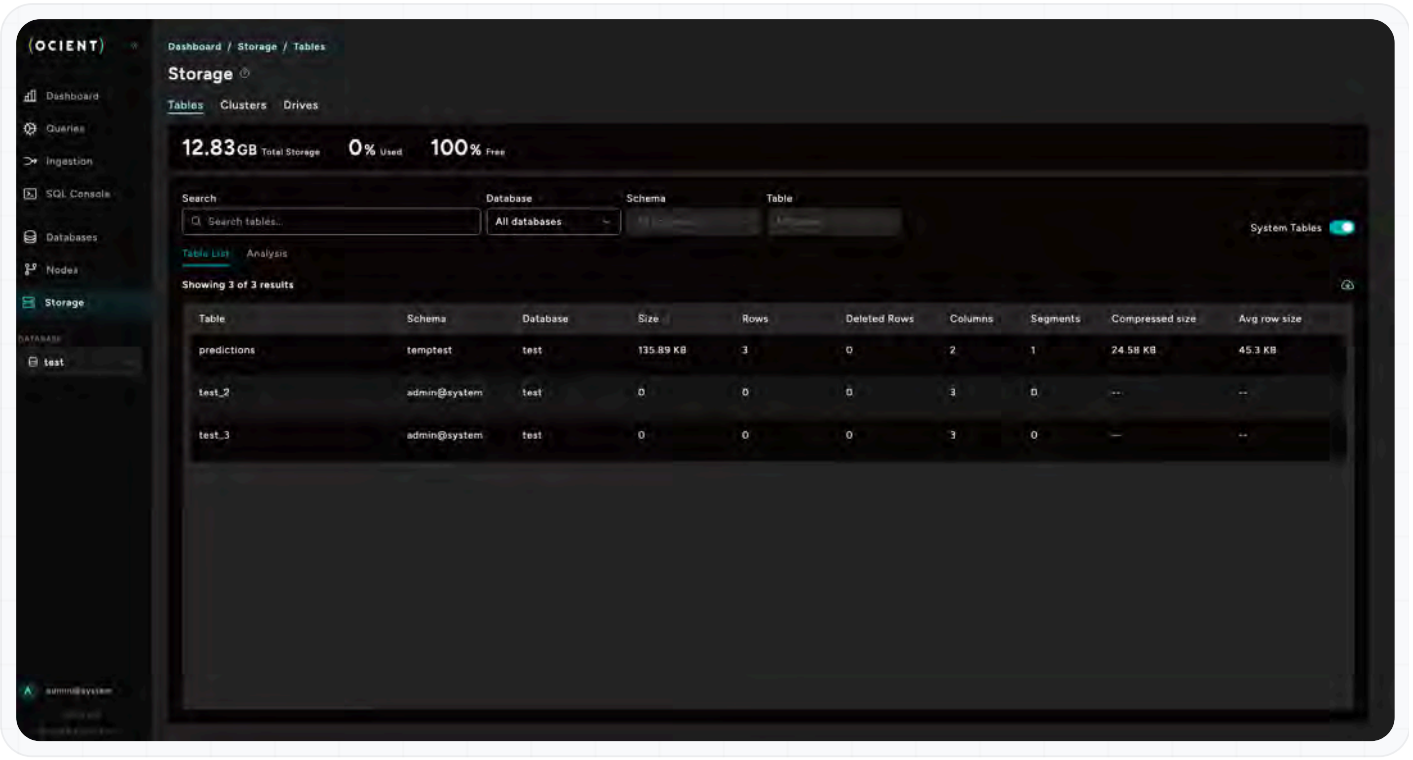
For details about database management, see **Database Administration**.

# Nodes

The Nodes page shows the health and status of every node in the system. A summary banner displays overall health percentage, total nodes, cores, RAM, drive health, and software version consistency. You can filter nodes by name, type, status, and software version. Each node entry shows its name, type, online status, storage utilization, uptime, and software version. Select a node (from this page or from the Dashboard page) to view its details and configuration.

To learn about the role of each node type, see **Core Elements of an Ocient System**.

# Storage



The Storage page provides visibility into the physical storage utilization of the system in these tabs:

- **Tables** — Lists each table with its schema, database, size, row count, deleted rows, columns, segments, compressed size, and average row size.
- **Clusters** — Shows storage cluster details.
- **Drives** — Shows individual drive status and utilization.

Summary statistics at the top display total storage, percentage used, and percentage free. You can search and filter tables by database, schema, and table name. The **Tables** tab includes an **Analysis** view that further breaks down storage by table and TimeKey® segment.

For details about storage configuration, see **Configure Storage Spaces**.

# Ocient Management UI Configuration

Connect to and configure the Ocient Management UI, including login, access control, ocui package management, connection endpoints, and SSL certificates.

The Ocient® Management UI is a web-based interface designed to support the primary tasks of database users without requiring command-line tools. Here, learn about how to connect to the UI, configure access control, and set up connection endpoints.

For an overview of UI features and pages, see **Ocient Management UI Features**.

## Connect to the UI

Learn how to connect to the Ocient Management UI remotely. This process assumes you have access to an Ocient System with the UI installed.

### Prerequisites

Any computer that you use to access the UI remotely must have:

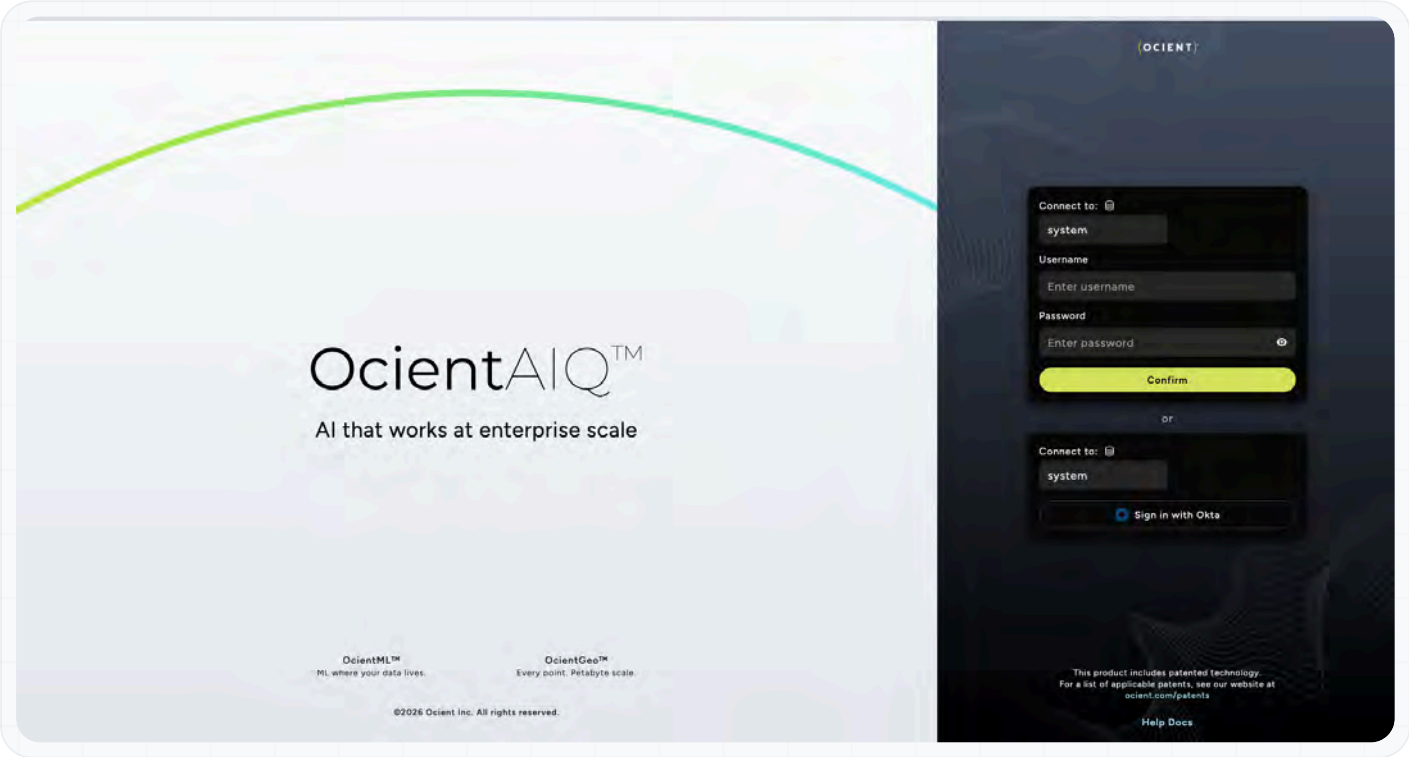
- Network access to an Ocient System with the UI installed
- Google® Chrome, Safari®, Microsoft® Edge, or Firefox® (latest version)

### Log Into the Ocient Management UI

Follow these steps to connect to your Ocient System from any machine with network access.

#### Navigate to the UI Using a Web Browser

To access the Ocient Management UI, use a web browser to navigate to the SQL Node using its IP address or hostname as a URL domain. This URL must use the `https` protocol.



© 2026 Ocient, Inc
Ocient Proprietary and Confidential

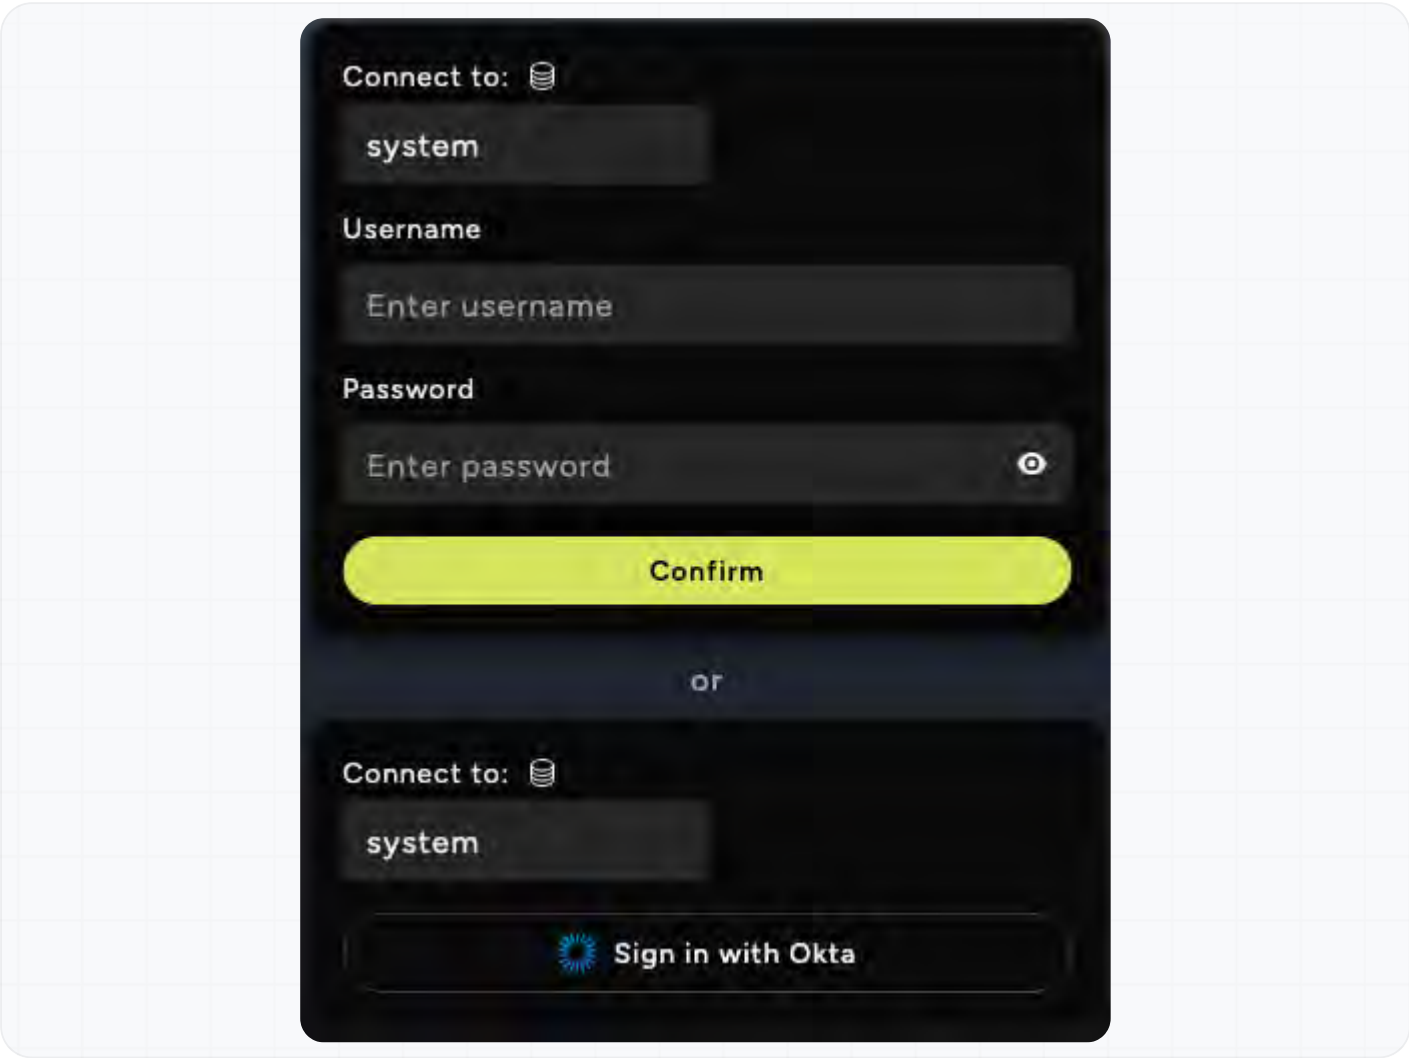
Your SQL Node connection information is available from your Ocient System or database administrators. For details, see **Configure Connection Endpoints**.

To connect, specify the SQL Node IP address or hostname.

```
https://<ip_or_hostname>
```

After loading, your web browser displays the Ocient Management UI login page.

## Select the Database



The Ocient Management UI can connect to individual databases or the default `system` database.

### Connect to the Default Database

By default, the login page connects to `system`, which gives you visibility into all databases where you have access. To create or modify tables or to execute data pipelines, connect to an individual database instead. For details, see **Manage Users, Groups, and Roles**.

### Connect to Your Database

To connect to your database, enter the name of the database in the **Connect to** field on the login page.

You can also change your active database connection after logging in using the database switcher in the sidebar navigation.

### Login Credentials

You can log in to the Ocient Management UI using either of these methods:

- User credentials (username, password).
- Single Sign-On (SSO) authentication — The UI supports multiple SSO integrations configured per database or Connectivity Pool.

For details about configuring SSO integrations, see **Authentication Methods**.

## Administration

Learn how to configure and administer the Ocient Management UI.

## Access Control

For full UI visibility and functionality, you must have read, create, and modify privileges on each database that you want to connect to.

These user roles have full visibility and functionality in the Ocient Management UI:

- `System Administrator`
- `Database Administrator`

Other roles can use the UI but have limited capabilities based on their privileges.

To assign user roles and privileges, see **Data Control Language (DCL) Statement Reference**.

## Install and Manage the ocui Package

The Ocient System includes a base version of the Management UI bundled with the core `ocient` package. The `ocui` package is a separate DEB or RPM package that allows you to update the Management UI without upgrading the entire Ocient System. Install the `ocui` package on any SQL Node where you want to host the updated UI.

When the `ocui` package version matches the installed `ocient` package version, the system hosts the UI from the `ocui` package. When the versions differ, the system falls back to the base UI included with the `ocient` package.

> For access to the `ocui` package, contact Ocient Support.

### Install the ocui Package

Transfer the `ocui` package file to the target SQL Node, then install it using the appropriate package manager command.

Install using DEB.

```
sudo dpkg -i ocui.deb
```

Install using RPM.

```
sudo dnf install ./ocui.rpm
```

After installation, verify that the Management UI is accessible by navigating to the SQL Node URL in a web browser. For details, see **Connect to the UI**.

### Verify the Installed Version

Use the package manager to check the installed `ocui` version on the SQL Node.

Check the version using DEB.

```
dpkg-query -W ocui
```

Check the version using RPM.

```
rpm -qa ocui
```

### Uninstall the ocui Package

Remove the `ocui` package from the SQL Node using the appropriate package manager command. After removal, the system reverts to the base Management UI included with the `ocient` package.

Remove using DEB.

```
sudo dpkg -r ocui
```

Remove using RPM.

```
sudo dnf remove ocui
```

## Configure Connection Endpoints

Access the Ocient Management UI by connecting to a SQL Node using the connection parameters set by its Connectivity Pool.

The Connectivity Pool defines a SQL Node connection configuration with:

- IP address
- Hostname
- Port
- SSO integration

For information on all Connectivity Pools created in your system, query the `sys.connectivity_pools` system catalog table.

For information on SQL Node connection parameters (IP address and network ports), query the `sys.connectivity_pool_participants` system catalog table.

To alter SQL Node connection parameters (IP address, port, and SSO integration), see **Cluster and Node Management**.

## Configure API Port

For network access, the Ocient Management UI requires a Connectivity Pool with an open port for the HTTP Query API. Follow these steps to ensure your port is accessible.

1. Identify the Connectivity Pool and SQL Node you want to use by querying the `sys.connectivity_pool_participants` system catalog table.

```
SELECT * FROM sys.connectivity_pool_participants;
```

2. In the system catalog output, check the `openapi_port` value for the Connectivity Pool and SQL Node you want to use. If this `openapi_port` value is `NULL`, the port is not open.
3. If you need to open the port or change its value, execute this statement using your Connectivity Pool and SQL Node names. This example uses port `443`, which is the default port for HTTPS traffic.

```
ALTER CONNECTIVITY_POOL <connectivity_pool_name>
    ALTER PARTICIPANT <SQL_node_name>
    SET openapi_port 443;
```

## Install SSL Certificates

The Ocient Management UI uses SSL certificates to connect to the system, similar to other methods such as the JDBC driver.

> By default, the system uses self-signed certificates. Using these certificates can result in the browser displaying an invalid certificate warning. For details about installing certificates, see **Secure Connections Using TLS**.

# Install an Ocient System

Install an Ocient System with this end-to-end guide covering hardware setup, OS preparation, application installation, node bootstrapping, and validation.

This section provides a quick tutorial for installing and configuring the Ocient® System using your data.

## Installation of the Ocient System

Before installing, check with your systems administrator to ensure that you meet the **Ocient System Requirements** for the validated operating systems and hardware needed for optimized Ocient performance.

The installation and configuration of the Ocient System involves these steps:

1. **Ocient Application Installation**

   This step details how to download and install the Ocient System package.

2. **Configure the Operating System**

   This step applies the required kernel parameters, including the hugepages configuration, and reboots the system.

3. **Ocient System Bootstrapping**

   This step describes the Ocient bootstrapping, which sets up the initial node configuration and connects the nodes together.

4. **Ocient Application Configuration**

   This step sets up your Ocient System with storage spaces, storage clusters, and node roles.

5. Verify the System Using the Management UI

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

> After installation and configuration, you can verify that your system is operational by accessing the **Ocient Management UI**. Navigate to the SQL Node URL in a web browser to view system health, node status, and storage utilization, create data pipelines, and execute SQL queries. For connection and setup details, see **Ocient Management UI Configuration**.

These pages provide additional information, validation tools, and configuration options for installing your Ocient® System.

- **Ocient System Sizing** — Guidance on the factors that influence Ocient System sizing.
- **Ocient System Requirements** — Information on hardware and system requirements for optimized Ocient performance.
- **Ocient System Hardware Specifications** — Information on the detailed hardware specification for the Ocient System.
- **Configure the Operating System** — A tutorial to configure the necessary prerequisites for system bootstrapping.
- **Checking System Configuration Before Bootstrapping** — Commands to capture critical node health states and metrics before beginning the bootstrapping process.
- **Checking System After Configuration** — Commands to capture critical node health states and metrics after the final configuration process.
- **Node Bootstrapping Reference** — Descriptions of additional options for advanced system configurations.

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# Ocient Application Installation

Install the Ocient application on supported Linux distributions, including package management, prerequisites, and post-install service verification steps.

You can install the Ocient® software application by installing a single RPM or Debian® package.

Before installation, review your hardware sizing and ensure that it meets your needs. For details, see **Ocient System Hardware Specifications**. For a list of prerequisites needed for Ocient installation, see the **Ocient System Requirements**.

For access to Ocient software packages, please contact Ocient Support.

## Application Installation

### Commands

Consult the documentation for the package manager of your operating system for specific options and command-line syntax.

## RPM Installation

Use this command to install the Ocient RPM package from the local file system. Include `./` or specify the full path to the RPM file; otherwise, the `dnf` command attempts to search the configured repositories instead of installing the local RPM file. In the following command example, replace `XX` with the Ocient package version of the provided file.

Shell

```
sudo dnf install ./ocient-XX-x86_64.rpm
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## DEB Installation

Use this command to install the Ocient DEB package from the local file system. Include `./` or specify the full path to the DEB file, otherwise the `apt` command attempts to search the configured repositories instead of installing the local DEB file. In the following command example, replace `XX` with the Ocient package version of the provided file.

Shell

```
sudo apt install ./ocient-XX-amd64.deb
```

## Next Step

When your system install completes, proceed to **Ocient System Bootstrapping**.

## Related Links

**Installation Reference**

**Install an Ocient System**

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# Configure the Operating System

Configure the Linux operating system on Ocient nodes, including kernel parameters, NUMA, huge pages, NVMe tuning, and network stack settings for performance.

The Ocient® System Configuration procedure assumes that these steps have been performed on the Foundation Nodes and Loader Nodes in the database cluster. Some of these steps require root user permissions.

Use `sudo` when performing these steps in your command-line interface.

### 1 Prepare the Operating System Configuration

You must prepare the operating system with this configuration to run Ocient software:

- Configure Network interface controllers (NICs) and firewall for use by Ocient.
- Set the timezone to UTC.
- If OPAL drives are installed, unlock or revert them to factory state.
- Optional: Mount points `/opt/ocient` and `/var/opt/ocient` are mounted on separate storage devices.

### 2 Confirm the Ocient Installation

To check the installation, run this command on each node to show the software version.

Shell

```
/opt/ocient/current/rolehostd --build-info
```

If the software is not installed or is the wrong version, see the **Ocient Application Installation** instructions.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### 3 Apply Required Kernel Settings

In order to achieve high-performance levels, you must set specific kernel settings. You cannot set these settings at runtime. Therefore, the system must pass these parameters to the kernel at boot time.

## Automatically Apply Kernel Settings

You can automatically configure the kernel settings and apply them by running the `ockernelparams` script in the Ocient software package. This script detects the current system hardware and adjusts the `grub` bootloader kernel parameters. Then, the script updates the `grub` configuration with `grub2-mkconfig` or `update-grub` (depending on the Linux® distribution).

Run this command and specify the appropriate node role.

Shell

```
/opt/ocient/scripts/ockernelparams --node-role {sql,loader,foundation,metad
```

You can also manually configure kernel settings. See **Manual Kernel Settings** for more information.

## Check Current Kernel Settings

Run this command to show the current settings for the kernel that is running.

You need to reboot after any changes are made to kernel parameters in the bootloader configuration.

Shell

```
cat /proc/cmdline
```

Text

```
BOOT_IMAGE=(hd0,gpt2)/boot/vmlinuz-4.18.0-305.19.1.el8_4.x86_64 root=UUID=1
```

The exact values can vary depending on the DRAM of the machine and the intended role for the node.

Check that the number of free 1G huge pages matches the number specified at the command line. You can check this number using this command.

Shell

```
cat /sys/kernel/mm/hugepages/hugepages-1048576kB/nr_hugepages
```

*Output*

Bash

```
1024
```

The returned value should match your configuration.

## Manual Kernel Settings

This section describes the optional kernel settings that you can manually configure. To automatically configure these settings, see **Automatically Apply Kernel Settings**.

You must add these settings that follow the `grub` bootloader kernel parameters for the listed applicable node types.

**Setting:** `transparent_hugepages`

Ocient requires that `transparent_hugepages` be disabled because Ocient software needs strict control over which huge pages it allocates.

**Applicable Node Types:**

- Foundation Nodes
- Loader Nodes
- SQL Nodes

**Kernel Setting:**

```shell
transparent_hugepage=never
```

**Setting:** `isolcpus`

To give Ocient software exclusive use of the majority of the cores on the system, the kernel is isolated from the cores using the `isolcpus` parameter. This isolation ensures that the system executes the kernel code only on a small number of cores where Ocient is not running logic that is critical for performance.

The pattern is to isolate all but the last two physical cores of each CPU from the kernel for CPUs with 26 or more cores. This means that two cores (four threads) per CPU are available to the kernel.

For CPUs with fewer than 26 cores, all but the last physical core of each CPU is isolated.

**Applicable Node Types:**

- Foundation Nodes

**Kernel Setting:**

- Dual 28-core CPUs (Intel® 6348)

```shell
isolcpus=0-25,28-53,56-81,84-109
```

- Dual 32-core CPUs (Intel 6338)

Shell

```
isolcpus=0-29,32-61,64-93,96-125
```

- Dual 96-core CPUs (AMD® 9654)

Shell

```
isolcpus=0-93,96-189,192-285,288-381
```

### Setting: Huge Pages

Ocient utilizes huge pages to streamline the management of large amounts of memory in the system. The system uses 2MB and 1GB huge pages, depending on the node type. These huge pages must be reserved at boot time because otherwise, the system memory quickly becomes too fragmented to allocate the number of huge pages needed at runtime. These settings are the expected huge page settings.

> Metadata Nodes do not use huge pages.

| Node Type | Installed DRAM | Huge Page Kernel Parameters |
|---|---|---|
| Foundation or SQL | 768 GB | `hugepagesz=1G hugepages=384` `hugepagesz=2M hugepages=16384` |

## 4 Prepare NVMe Drives

> These steps are for Foundation Nodes, Loader Nodes, and SQL Nodes only.

To prepare NVMe drives on Foundation Nodes, Loader Nodes, and SQL Nodes, these nodes must be in a state where they are connected to the uio_pci_generic or vfio-pci driver and not contain a partition table. To initialize the drives for use by Ocient that have been previously partitioned, you must perform these steps.

1. Identify the OS drives. The OS drives have partitions that are mounted to mount points such as `/`. In this example, `nvme0n1` is the OS drive.

Shell

```
lsblk
NAME        MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
nvme0n1     259:0    0  1.8T  0 disk
├─nvme0n1p1 259:1    0  512M  0 part /boot/efi
└─nvme0n1p2 259:2    0  1.8T  0 part /
```

2. Ensure all drives are bound to the NVMe driver so the NVMe drives show up as standard NVMe devices. List the NVMe drives to identify the drive identifiers.

Shell

```
sudo /opt/ocient/scripts/nvme-driver-util.sh bind-nvme

/opt/ocient/scripts/nvme-driver-util.sh

BDF     Numa Node   Driver name     Device name
0000:01:00.0    0       nvme            nvme0n1
0000:3b:00.0    0       nvme            -
0000:3c:00.0    0       nvme            -
0000:5e:00.0    0       nvme            -
0000:5f:00.0    0       nvme            -
0000:86:00.0    1       nvme            -
0000:87:00.0    1       nvme            -
0000:88:00.0    1       nvme            -
0000:89:00.0    1       nvme            -
```

3. For each NVMe drive that you need to erase and prepare for Ocient (not the OS drive), run this command by replacing `X` and `Y` to match the device name.

Shell

```
sudo nvme format /dev/nvmeXnY format --ses=1
```

⚠ This command formats the specified drive and erases all data on the drive. Ensure that the OS drive is not formatted if it is an NVMe drive.

Some drives do not support the `nvme format` command. In that case, you can overwrite the partition table by zeroing out the beginning of the drive with this command. This command does not securely erase the whole drive, but does allow it to be used by Ocient.

Shell

```
sudo dd if=/dev/zero of=/dev/nvmeXnY bs=1024K count=1024
```

4. Bind the drives to the UIO or VFIO driver by running this command. The script automatically chooses the appropriate driver after detecting if the `IOMMU` setting is enabled. Any NVMe drives with mounted partitions (i.e. the OS drive) remain on the NVMe driver. Show all expected NVMe drives on the node attached to the UIO or VFIO driver.

Shell

```
sudo /opt/ocient/scripts/nvme-driver-util.sh bind-vfio

/opt/ocient/scripts/nvme-driver-util.sh

BDF     Numa Node   Driver name     Device name
0000:01:00.0    0       nvme            nvme0n1
0000:3b:00.0    0       vfio-pci        -
0000:3c:00.0    0       vfio-pci        -
0000:5e:00.0    0       vfio-pci        -
0000:5f:00.0    0       vfio-pci        -
0000:86:00.0    1       vfio-pci        -
0000:87:00.0    1       vfio-pci        -
0000:88:00.0    1       vfio-pci        -
0000:89:00.0    1       vfio-pci        -
```

## 5 Clear Files from Any Previous Ocient Setup

To bootstrap a node that was previously part of an Ocient System, you must clear a set of files from any previous setup of Ocient from the `/var/opt/ocient/` directory. These commands remove these files.

Shell

```
sudo rm -f /var/opt/ocient/rolehostd.conf
sudo rm -f /var/opt/ocient/ocient.key
sudo rm -f /var/opt/ocient/ocient.crt
sudo rm -f /var/opt/ocient/ocient.crt.original
sudo rm -f /var/opt/ocient/*.raft
sudo rm -f /var/opt/ocient/bootstrap.completed
```

© 2026 Ocient, Inc

Do not remove files in the `localKeyStore` directory if OPAL drives are present and encryption is not disabled. If these files are removed, the drive encryption must be reset using an external utility.

# Ocient System Bootstrapping

Bootstrap an Ocient System by initializing nodes, configuring storage spaces, and validating cluster membership to prepare for production workloads.

The Ocient® System runs the bootstrapping process one time per node. This process establishes the node identity, configures networking, and accepts nodes into the system.

The `/var/opt/ocient/bootstrap.conf` file controls the initial configuration of each node. The system uses this file only when the node initially starts.

## Validate the System Before Bootstrapping

The following steps assume a basic OcientAIQ™ Unified Data Platform configuration, where every node has a single network interface.

To verify your system before the bootstrapping process:

- Check with your systems administrator to ensure that you meet the **Configure the Operating System** requirements. Before bootstrapping, your system must meet the requirements described in the **Apply Required Kernel Settings** and **Prepare NVMe Drives** sections.
- You can run a system check to validate the compliance of hardware, nodes, and the configuration for the Ocient System. For details, see **Checking System Configuration Before Bootstrapping**.

## Initial Configuration

The system automatically initializes the first node bootstrapped in the system with the SQL and Administrator roles. Choose a node to serve as a SQL Node. This node is the initial node in the system. The hardware for each node type differs, so ensure that the node you select is intended for a SQL Node.

For new clusters, if you do not define the configuration for the SQL Nodes in a connectivity pool, the Ocient System assigns each SQL Node to their own unique connectivity pool named `<sql_node_name>_default`, where `<sql_node_name>` is the

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

name of the SQL Node. However, the most common configuration of an Ocient System has all SQL Nodes in one connectivity pool.

For an example of adding SQL Nodes to a connectivity pool, see **CREATE CONNECTIVITY POOL**. Change or troubleshoot the default configuration using the instructions in **Manage the Network Configuration of an Ocient System**.

## Ocient System Bootstrapping Process

If you meet the system prerequisites, you can begin bootstrapping your Ocient System.

The bootstrapping process consists of these steps:

1. **Bootstrap the First Node**
2. **Bootstrap the Remaining Nodes**

### 1 Bootstrap the First Node

#### Bootstrap the Node

Connect to the initial SQL Node with the username and password of your server and the IP address of your node. This example connects as the administrator `admin` to the IP Address `10.10.10.10`.

Shell

```
ssh admin@10.10.10.10
```

Use your preferred text editor with `sudo` to create the `/var/opt/ocient/bootstrap.conf` file as root with these contents.

**`/var/opt/ocient/bootstrap.conf` example**

YAML

```
initialSystem: true
```

Start the database.

```shell
sudo systemctl start rolehostd
```

Verify that the node and the service are active by executing this status command.

```shell
systemctl status rolehostd

rolehostd.service - Rolehostd daemon startup
     Loaded: loaded (/etc/systemd/system/rolehostd.service; enabled; vendor
     Active: active (running) since Wed 2022-01-26 23:31:36 UTC; 7s ago
     ...
```

If the `rolehostd` service is running, you can also check the Ocient logs on your node. Search and ensure there are no [ERROR] log messages.

```shell
tail -f /var/opt/ocient/log/rolehostd.log
```

## Verify Connection to the SQL Node

At this point, you have a running database with a single node. You should be able to connect to the database using **Connect Using JDBC** or **Connect Using pyocient** and execute commands.

Every new system starts with a `system` database. To connect to a new system, use the username and password configured in the `bootstrap.conf` file or the username `admin@system` and password `admin` if none was provided.

For example, assume your node named `sql0` has an IP address of `10.10.0.1`. Use the JDBC driver CLI to connect with this connection string.

Shell

```
connect to jdbc:ocient://10.10.0.1:4050/system user "myuser@system" using "
```

See the **JDBC Manual** for details on using the JDBC driver.

To see the roles running on the single node, execute this query.

SQL

```
select name, operational_status, software_version, array_agg(service_role_t
        from sys.node_status as ns
        left join sys.nodes as n  on ns.node_id = id
        left join sys.service_roles as sr on sr.node_id = n.id
        group by name, operational_status,software_version;
```

The initial node should be listed as running the `sql`, `admin`, `health`, and `operatorvm` roles. If all of these roles are present and the node is Active, you can proceed to the next step to bootstrap the remaining nodes.

## 2 Bootstrap the Remaining Nodes

Performing the bootstrapping process on the remaining nodes is identical on all nodes. The remaining nodes can be bootstrapped in any order.

On each node, log in using SSH and use your text editor with `sudo` to create the file `/var/opt/ocient/bootstrap.conf` that contains this text by replacing `<FIRST_NODE_IP_ADDRESS>` with the IP address of the initial node you created in Step 1.

### `/var/opt/ocient/bootstrap.conf` example

YAML

```
adminHost: <FIRST_NODE_ADDRESS>
nodeToken: <token_from_GET_NODE_TOKEN>
```

`<FIRST_NODE_ADDRESS>` is the DNS name or IP address of the initial node. Generate a `nodeToken` value by executing the `GET NODE TOKEN` SQL statement using a database connection to the initial node. Each token is single-use, so you must generate a separate token for every joining node. The default token lifetime is 15 minutes. Generate each token shortly before starting the corresponding node, or specify a longer time-to-live (TTL) if needed.

> You can obtain the IP Address of the initial node by executing `ifconfig` on that node.

> You can also use `adminUserName` and `adminPassword` instead of `nodeToken`, but this approach is deprecated. Use node tokens for improved security. If the password for the system administrator has changed, set the correct username and password in `bootstrap.conf`.

On each node, start the database.

Shell

```
sudo systemctl start rolehostd
```

> When you replace Foundation Nodes, the Ocient System removes the prior node after the creation of the new node. Some queries of the system catalog tables might not return results until the prior node is removed.

At this point, all the remaining nodes are not configured with any roles. After all nodes have been started, you should see them when you execute this query with only the `health` role listed. This query uses the `sys.node_status`, `sys.nodes`, and `sys.service_roles` system catalog tables to retrieve node information for the node name, operation status, version, and all service role types. The query uses the **ARRAY_AGG** function to retrieve the service role type for all rows.

SQL

```
SELECT name, operational_status, software_version, array_agg(service_role_t
    FROM sys.node_status AS ns
    LEFT JOIN sys.nodes AS n ON ns.node_id = id
    LEFT JOIN sys.service_roles AS sr ON sr.node_id = n.id
    GROUP BY name, operational_status,software_version;
```

## More Bootstrapping Options

For options on bootstrapping your Ocient System, see **Node Bootstrapping Reference**.

## Next Step

When you have completed the bootstrapping process, you can proceed to the **Ocient Application Configuration** page to finish configuring Ocient.

# Related Links

# Ocient Application Configuration

Configure the Ocient application for production deployments, including service settings, storage spaces, network bindings, security, and performance parameters.

These steps assume that you have already completed the process for bootstrapping your Ocient® System nodes. If you have not done this yet, perform the **Ocient System Bootstrapping** steps before beginning this configuration process.

Now that the nodes have all completed bootstrapping, you must properly configure the nodes to perform their roles. You should run these commands using a SQL connection to one of the SQL Nodes in your system. For details, see **Connect to Ocient**.

The Ocient application configuration process consists of these steps:

1. **Creating a Storage Space**
2. **Creating Storage Clusters**
3. **Assigning Service Roles**
4. **Restart the Nodes**

## 1 Creating a Storage Space

To create a storage space with 12 segments, use `WIDTH=12` and `PARITY_WIDTH=2`. Two of these segments are the parity portion, and 10 of these segments are the data portion.

SQL

```
CREATE STORAGESPACE teststoragespace WIDTH = 12, PARITY_WIDTH = 2;
```

The storage space name must begin with a letter followed by letters, numbers, and underscores.

© 2026 Ocient, Inc

You can view all storage spaces in the system by querying the `sys.storage_spaces` system catalog table.

SQL

```
SELECT * FROM sys.storage_spaces;
```

For details about creating a storage space to suit your system needs, see **Configure Storage Spaces**.

### 2 Creating Storage Clusters

You must have at least one storage cluster to configure an Ocient System. A storage cluster is a set of Foundation Nodes with an associated storage space that coordinate to reliably store data and serve queries.

Create a Foundation cluster.

SQL

```
CREATE CLUSTER lts_cluster
TYPE LTS storagespace "teststoragespace"
PARTICIPANTS=('lts0','lts1','lts2','lts3','lts4','lts5','lts6','lts7','lts8
```

Loader Nodes and SQL Nodes do not need to be placed into a cluster.

At a minimum, the number of participants must be the width specified in the storage space. This number can be greater if you overprovision the system. For details about storage spaces and related settings, overprovisioning, and parity, see **Core Elements of an Ocient System**.

View all clusters in the system.

SQL

```
SELECT * FROM sys.clusters;
```

View all clusters and their associated nodes.

SQL

```
SELECT c.name AS cluster_name, c.cluster_type, n.name AS node_name
FROM sys.node_clusters nc
JOIN sys.clusters c ON nc.cluster_id = c.id
JOIN sys.nodes n ON nc.node_id = n.id;
```

⚠ You must restart all nodes with the SQL role after adding a storage cluster.

### 3 Assigning Service Roles

Assign service roles to each accepted node. This process defines how each node participates in queries and the management of the system.

View all nodes and their configured roles.

SQL

```
SELECT n.name AS node_name, sr.service_role_type
FROM sys.nodes n
LEFT JOIN sys.service_roles sr ON sr.node_id = n.id;
```

The addition of nodes to the storage cluster in the prior step automatically assigns `lts` to the Foundation Nodes that you included.

Add the remaining `sql`, `admin`, and `streamloader` roles to the appropriate nodes.

SQL

```
ALTER NODE "sql1" ADD ROLE sql;
ALTER NODE "sql1" ADD ROLE admin;
ALTER NODE "loader1" ADD ROLE streamloader;
```

© 2026 Ocient, Inc

The `Admin` role can operate standalone or on the same node as the `SQL` role.

### 4 Restart the Nodes

With roles assigned to the nodes, you can restart the `rolehostd` process on all nodes. At a shell terminal on each node, run this command.

Shell

```
sudo systemctl restart rolehostd
```

If any custom configuration settings are applied to running nodes during other configurations, be sure to restart the `rolehostd` process before proceeding.

You can check the status of nodes using the Status endpoint on each node from a terminal. Assuming IP Addresses `10.10.0.2` and `10.10.0.3` for `sql1` and `lts0`, respectively, you can check the status with these curl commands.

CURL

```
curl http://10.10.0.2:9090/v1/status
curl http://10.10.0.3:9090/v1/status
```

After all of the nodes are `Active`, Ocient is ready to use for queries.

## Creating an Ocient System with Multiple Storage Clusters

If you need an Ocient System that requires 10 or more Foundation Nodes in the storage cluster, then you can create multiple storage clusters. For considerations to take into account when you work with multiple storage clusters, see **Multiple Storage Clusters for Loading Data**.

Create a multiple storage cluster with 12 nodes. Create a storage space `store` with width `5` and parity width `1` using the `CREATE STORAGESPACE` SQL statement.

SQL

```
CREATE STORAGESPACE store WIDTH = 5, PARITY_WIDTH = 1;
```

Create multiple clusters using the `CREATE CLUSTER` SQL statements using the storage space `store`. Split the Foundation Nodes among the clusters. `cluster_0` storage cluster has Foundation Nodes `lts0` through `lts5`, while `cluster_1` has `lts6` through `lts11`.

SQL

```
CREATE CLUSTER cluster_0 TYPE=lts PARTICIPANTS=("lts0", "lts1", "lts2", "lts3", '

CREATE CLUSTER cluster_1 TYPE=lts PARTICIPANTS=("lts6", "lts7", "lts8", "lts9", '
```

## Validating the System After Configuration

After configuration, you can run a system check to validate the Ocient installation and bootstrapping. For details, see **Checking System After Configuration**.

## Next Step

Follow the process in **Ingest Data with Legacy LAT Reference** to create a database and a table, then load data from a set of files located on a cloud object storage.

# Ocient System Sizing

Size an Ocient System for your data and query needs by gathering uncompressed data size, format, compression ratios, load rates, and query types for capacity.

The Ocient® System must be the proper size for your data and query requirements. Follow these steps to determine the size of your Ocient System. Contact **Ocient** to aid with the Ocient System calculations, established configuration, and node quantities.

1. Gather the uncompressed size of your current database or data and its format. If your data resides in a database, determine the compression ratio of the data. Further, consider whether your data is streaming or file-based. For streaming or time series data, investigate the level of data granularity (for example, minute, hour, or day).
2. Calculate the quantity of data (in Gbps or the number of rows in a specific unit of time) that you plan to load into the Ocient System and at what cadence (for example, continuous loading or specific schedule). Describe the latency you expect between the data creation and when data reaches the destination. As you consider the quantity, determine the percent of NULL data. Also, think about the retention period required for the data.
3. Determine the level (small, medium, or large) of data transformation in the data pipeline loading process. See whether you require any user-defined transformations. Investigate whether your transformations are done programmatically or using SQL. After the initial data load, see if you require more transformations, such as cubes or views.
4. Investigate the types of queries you plan to execute (for example, simple filters, complex aggregation or sorting, complex joins, or transformation). In addition, review your query workload (number of queries in a specific unit of time) and how many queries you expect to execute in parallel. Consider any objectives you have for system readiness to execute queries.
5. Calculate the compressed data volume. Consider your compression requirements for the stored data (for example, Global Dictionary Compression).

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

6. Add index, statistics, working space, and parity size to the compressed data volume.
7. Use the established storage space configuration in the Ocient System for data nodes, parity nodes, and the number of clusters.
8. Using the known size and level of transformation in loading, determine the total number of cores, memory, and storage for your requirements.
9. Calculate the number of SQL Nodes, Loader Nodes, Foundation Nodes, Metadata Nodes, and supporting nodes. Ocient personnel assist with this step.

The number of specific nodes determines the size of the Ocient System. After you have the latter numbers, then you can purchase, install, and configure the system.

# Ocient System Requirements

Hardware and software requirements for running an Ocient System, including supported CPUs, memory, NVMe storage, networking, and operating system versions.

In order to run the OcientAIQ™ Unified Data Platform, you must meet several requirements for your system hardware, OS, and software. The requirements ensure that your system can run an optimized and fully functional Ocient® installation.

These requirements apply to the Foundation, Loader, and SQL Nodes.

> Consult with Ocient or the System Administrator installing Ocient to determine the optimal configuration for your Ocient deployment.

## Server Hardware Requirements

These are the hardware requirements for the OcientAIQ Unified Data Platform node servers. These requirements include the Foundation, Loader, SQL, and Metadata Node types. Data (i.e., non-OS) drive requirements are listed separately.

### Foundation, Loader, and SQL Nodes

| Component | Requirements | Notes |
|---|---|---|
| Chassis/System | 8+ NVMe hotswap bays<br>Dual CPUs<br>M.2 slots for OS drives<br>Redundant power supplies | Supermicro® SYS-120U-TNR or similar recommended<br>Full bandwidth PCIe connections to NVMe drives are recommended (i.e., not attached to a RAID card and not multiplexed). Drives must appear as `nvme` devices.<br>NVMe PCIe lanes balanced between CPUs recommended (i.e. equal number of drives connected to CPU1 and CPU2). |
| CPU | 2x Intel® Skylake or AMD® Rome or newer x86-64 server CPUs | 26+ cores per CPU recommended.<br>Must support AVX2 instruction set. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Component | Requirements | Notes |
|---|---|---|
| Memory | 1TB+ recommended<br>All CPU memory channels must be populated to achieve maximum memory bandwidth. | Balanced memory configuration with all memory channels populated required to achieve maximum bandwidth. |
| High Speed Network | 100Gbit dual port ethernet NIC | NVIDIA® Mellanox® ConnectX-5 MCX516A-CCAT recommended.<br>Dual ports required for redundancy. |
| OS Drives | 1TB+ Enterprise NVMe drives (M.2) | RAID-1 mirroring recommended.<br>M.2 format recommended to keep all U.2 bays available for data drives. |
| Data Drives | See **Data Drive Requirements**. | NVMe drives for short-term and long-term data storage. |

## Metadata Nodes

The optional Metadata Nodes have fewer requirements than the other nodes.

| Component | Requirements | Notes |
|---|---|---|
| Chassis/System | Virtual Machine or Physical Machine | No specific chassis requirements. The system can be a virtual machine. |
| CPU | 16+ cores Xeon-D or similar x86-64 CPU | Must support AVX2 instruction set.<br>You might need to change the virtual machine CPU type to support AVX2 instructions. |
| Memory | 64GB | None. |
| Network | 10 Gbps NIC or virtual NIC | Metadata Nodes do not require high-speed networking.<br>Dual ports are required for redundancy. |
| OS Drive | 512GB Enterprise SSD or SSD-backed storage pool | NVMe is recommended. |

# Data Drive Requirements

Ocient strictly requires high-performance enterprise or data center NVMe SSD drives for long-term and short-term data storage. The drives listed here have been validated for functionality and performance. They also support drive self-encryption using the OPAL standard. All data stored is encrypted at rest. Power loss protection (PLP), standard on

enterprise and datacenter drives, is also required. An endurance of 0.5 drive writes per day (DWPD) or higher is recommended for Foundation and SQL Nodes, endurance of 1.0 DWPD is recommended for Loader Nodes.

- Solidigm™ D5-P5430 OPAL U.2 3.84TB-15.36TB
- Solidigm D7-P5520 OPAL U.2 1.92 TB-15.36TB
- Solidigm D7-P5510 OPAL U.2 3.84TB, 7.68TB
- Samsung® PM9A3 U.2 960GB-15.36TB
-

> ⚠ Solidigm P5510 firmware versions VDV10151 and VDV10152 are known not to work properly with OPAL enabled. Upgrade the firmware to a known working version.

> ⚠ Samsung PM9A3 firmware versions GDD5102Q and GDD5202Q are known to have issues with the `vfio-pci` driver. Upgrade the firmware to a newer version.

Enterprise NVMe drives with similar or better performance characteristics and OPAL (or better) support can be considered for validation.

> ⓘ If the Ocient System detects hardware support for the OPAL standard, then nodes enable full disk encryption on data drives by default. Ocient stores the encryption keys on the operating system drive. For the complete list of directories to back up, see **Backup and Restore**.

### Compatible Operating System Versions

These operation systems and versions are fully supported by Ocient:

- Red Hat® Enterprise Linux® (RHEL®) version 8* and version 9
- Ubuntu® 20.04, 22.04, 24.04
- Debian® 11, 12

> ⓘ RHEL versions 8.3 and prior require a kernel upgrade for compatibility. There is a bug in the `uio_pci_generic` driver in the kernel provided with those versions that prevents Ocient from communicating with the NVMe drives.

## Network Requirements

Ocient requires high-bandwidth connections between its database nodes to achieve high performance. It is critical for performance that the Foundation and SQL Nodes can simultaneously utilize high-bandwidth links without bottlenecks. Generally, this means that those nodes share the same switch backplane for best performance.

> The minimum recommended link speed is 100Gbps.

### Redundancy

Redundant networking is recommended for production use cases. On the server side, dual port NICs are required to support redundancy. Multi-chassis link aggregation (MLAG/CLAG/MCLAG) using redundant switches is the recommended form of redundancy.

### Network Switch

These are the requirements for the network switches to support Ocient. No other advanced L2 or L3 features are required.

1. Enough 100G ports for all Foundation Nodes on the same backplane for best performance.
2. Multi-chassis link aggregation for redundancy (MLAG/CLAG/MCLAG depending on vendor terminology).

## Security Requirements

To secure data stored on disk, Ocient supports and recommends SEDs (Self-Encrypting Drives) that meet the OPAL (or better) standard. Using drives that support this standard, Ocient software enables encryption of data at rest on the drives. This encryption prevents unwanted data leaks, as any time a disk is removed from the system, it becomes locked, and the data can only be recovered with a key-encrypting-key that is stored off-drive.

To secure network communications, see the **Ocient Security Guide**.

## Additional Software Requirements

Ocient depends directly on these software packages:

- `python3`

- `sudo`
- `lz4`
- `cronie`
- `logrotate`
- `gzip`
- `pciutils`
- `ca-certificates`
- `libquadmath` (RHEL), `libquadmath0` (Ubuntu/Debian)

For database nodes, these packages are installed automatically as part of the package dependencies.

Ocient also depends on a separate installation of Java® 21, where the `openjdk-21-jre-headless` package is recommended.

## Next Step

If your system meets these requirements, proceed to **Ocient Application Installation**.

# Ocient System Hardware Specifications

Hardware specifications for Foundation, Loader, and SQL Nodes in an Ocient System, with supported components, performance specs, and deployment guidance.

Depending on your deployment modality and your purchase agreement with Ocient®, the Ocient System can run on hardware bearing the Ocient brand. Here, you can learn about the specifications for the hardware. However, an Ocient System can run on generic hardware that meets the system requirements. For details, see **Ocient System Requirements**.

The Ocient System contains Foundation Nodes, Loader Nodes, and SQL Nodes. For details about these node types, see **Core Elements of an Ocient System**.

For sizing considerations, see **Ocient System Sizing**. Then, you can further optimize the system by using compression at the table level. For details, see **Table Compression Options**. After you have the hardware and size defined, you can install the Ocient System. For details, see **Install an Ocient System**.

## Foundation Node Specifications

### Components

This table provides the components and their descriptions and quantities for the hardware.

| Component | Description | Quantity |
|---|---|---|
| Chassis | Supermicro® Hyper A+ Server AS -2126HS-TN — 24 NVMe Drive 2.5” drive bays<br>For details, see the **Hyper A+ Server AS -2126HS-TN specification**. | 1 |
| Processors | Dual AMD® EPYC™ 9654 Processors — 96 cores per processor | 2 |
| Memory | 96GB DDR5-4800 RDIMM | 24 |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Component | Description | Quantity |
|---|---|---|
| 100Gbps NIC | NVIDIA® Mellanox® 100Gbps Network Card — MCX623106AN-CDAT PCIE 2port 100GB QSFP28 | 1 |
| Trusted Platform Module (TPM) | TPM 2.0 | 1 |
| Boot Drive RAID Carrier | AOC-SLG4-2H8M2-O, 2x Hybrid Gen 4 NVMe/SATA M.2 RAID 0/1 Carrier, Standard | 1 |
| DCMS License | Supermicro Data Center Management Suite License | 1 |
| Boot Drive | Samsung® PM983 1.9TB 1 DWPD NVMe PCIe3x4 M.2 22x110 SED | 3 |
| Storage Drives | Solidigm™ D5-P5430 [7.68TB, 15.36TB, 30.2TB] NVMe U2 15 mm SED | 12 |

## Physical Specifications

This table provides the specifications and their corresponding values for the hardware.

| Specification | Value |
|---|---|
| Form Factor | 2U Rackmount |
| Height | 3.5” (88.9 mm) |
| Width | 17.2” (437 mm) |
| Depth | 31.74” (806.2 mm) |
| Package | 9.96” (H) x 26.46” (W) x 43.31” (D) |
| Net Weight | 45 lbs (20.5 kg) |
| Gross Weight | 75 lbs (34 kg) |
| Operating Temperature: | 10°C to 35°C (50°F to 95°F) |
| Non-operating Temperature | -40°C to 70°C (-40°F to 158°F) |
| Operating Relative Humidity | 8% to 90% (non-condensing) |
| Non-operating Relative Humidity | 5% to 95% (non-condensing) |
| Power supplies | 2000W Redundant Power Supplies |
| Peak Load Wattage | 1350W |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Specification | Value |
|---|---|
| Average Load Wattage | 810W (varies based on workload) |
| Min Load Wattage | 240W |

### Performance Specifications

This table provides different foundation hardware performance specifications for Foundation Nodes.

| Node Type | Cores | Memory (TB) | Drives (TB) | Drives (Numbe |
|---|---|---|---|---|
| Foundation Node — Large Storage Optimized | 192 | 2.3 | 7.68 | 12 |
| Foundation Node — Extra Large Storage Optimized | 192 | 2.3 | 15.36 | 12 |
| Foundation Node — Double Extra Large Storage Optimized | 192 | 2.3 | 30.72 | 12 |

## Loader Node and SQL Node Specifications

The components, specifications, and sizing for Loader Nodes and SQL Nodes are the same.

### Components

This table provides the components and their descriptions, and quantities for the hardware.

| Component | Description | Quantity |
|---|---|---|
| Chassis | Supermicro Hyper A+ Server AS -2126HS-TN — 24 NVMe Drive 2.5” drive bays<br>For details, see the **Hyper A+ Server AS -2126HS-TN specification**. | 1 |

# Checking System Configuration Before Bootstrapping

Validate Ocient System configuration before bootstrapping nodes, including hostnames, networking, disk layout, and configuration files to prevent setup errors.

The `precheck` command helps capture critical node health states and metrics before bootstrapping your Ocient® installation.

You can run the command as shown in this example. The flags included after the `precheck` command are optional. See **Optional Flags for Command Execution** for descriptions.

Shell

```
$ sudo precheck --print-level verbose --node-type metadata --logfile-location /home
```

The command invokes a script from the command line on operating systems supported by Ocient. The script sends output to standard output (STDOUT) and standard error (STDERR). To specify the file option, use this flag: `--logfile-location <directory>` where `<directory>` is the directory where the `precheck` command creates the log file. Critically, this script captures information about huge page configuration.

## Optional Flags for Command Execution

Use the `precheck` command to run the script that checks the system configuration. You can execute the command using the optional flags shown in this table.

| Flag Name | Values | Default | Description |
|---|---|---|---|
| —logfile-location | Non-empty string | `/var/opt/ocient/log` | Name of the directory that contains the log file created from the execution of the script. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Flag Name | Values | Default | Description |
| --- | --- | --- | --- |
| —print-level | verbose or silent | verbose | Denotes the level of detail in the output. See the “Outputs” section. |
| —node-type | metadata, lts, streamloader, sql, or unknown | unknown | Denotes the current node type. If you do not specify this setting, the script tries to infer node type based on metrics it collects. |
| —timeout | Any integer | 3 | Denotes the default timeout (in seconds) to run any command-line command in the script. In most cases, the default is enough, so you do not need to specify this setting. |
| —nvme-driver-util-path | Non-empty string | /opt/ocient/scripts/nvme-driver-util.sh | Path to `nvme-driver-util` script that the precheck scrip uses. The default value is the location of the script on most installations, so in most cases, you do not need to specify this setting. |

| Flag Name | Values | Default | Description |
| --- | --- | --- | --- |
| —json | Not applicable | False | If you specify the `--json` flag, the command prints output in JSON format to STDOUT. If you do not specify this flag, the commanc prints human-readable output to STDOUT. |

## Command Output

The command has two types of output, silent or verbose, which you can specify by using the `--print-level` flag at the command line.

### Silent

The `silent` value for the `--print-level` flag only produces a status code. The code is 0 for success, 1 for error, and 2 for warning.

### Verbose

The `verbose` value for the `--print-level` flag prints either human-readable output by default or output in JSON format (if you specify the `--json` flag). The output contains all status details.

This example shows human-readable output.

# Checking System After Configuration

Verify that an Ocient System is healthy after configuration by checking node status, storage spaces, network connectivity, and core service operation.

The `postcheck` command helps capture critical node health states and metrics after the Ocient® configuration process.

You can run the command as shown in this example. The flags included after the `precheck` command are optional. See **Flags for Command Execution** for descriptions.

Shell

```
$ sudo /usr/local/bin/postcheck --dsn ocient://<user>:<password>@<host>:<port>/<dat
```

This table describes each placeholder in the DSN:

| Placeholder | Description |
|---|---|
| `<user>` | The username for the Ocient database connection (for example, `admin@system`). |
| `<password>` | The password associated with the specified user. |
| `<host>` | The hostname or IP address of the SQL Node to connect to. |
| `<port>` | The port number on which the SQL Node is listening. |
| `<database>` | The name of the database to connect to. |

The command invokes a script from the command line on operating systems supported by Ocient. The script sends output to standard output (STDOUT) and standard error (STDERR) with the option to send a text file or a JSON file.

To specify the file option, use this flag: `--logfile-location <directory>` where `<directory>` is the directory where the `postcheck` command creates the log file.

Before you begin, ensure that all steps in the **Ocient System Bootstrapping** process are complete.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Prerequisites

The script requires Java® and the Ocient JDBC JAR to run. In most cases, you should use this script on client servers rather than database nodes.

To get the post-check script onto a client, perform the `scp` operation on the wheel onto the server and run `python3 -m pip install --no-index <path_to_wheel>/postcheck*.whl`, and replace `<path_to_wheel>` with the path to the directory of the wheel file on your server.

## Flags for Command Execution

Use the `postcheck` command to run the script that checks the system configuration after you configure Ocient. You can execute the command using these flags.

| Flag Name | Required | Values | Default | Descript |
|---|---|---|---|---|
| —dsn | Yes | Many | Not applicable | Data sour (DSN). Th prompts f credentia |
| —logfile-location | No | Non-empty string | /var/opt/ocient/log | Name of contains t created fr execution |

# Node Bootstrapping Reference

Access reference documentation for bootstrapping individual nodes in an Ocient system, optimizing for scalability and reliability.

## Bootstrap a Node

### 1 Connect to the Node

To bootstrap an Ocient® node, connect to the node with your server username and password and the IP address of your node.

For example, connect as administrator `admin` to the IP Address `10.10.10.10`.

Shell

```
ssh admin@10.10.10.10
```

### 2 Configure the Bootstrap Configuration File

Use your preferred text editor with `sudo` to create the `/var/opt/ocient/bootstrap.conf` file as root.

For a list of bootstrapping options, see **Supported Options**.

#### Option 1: Bootstrap the initial node in a system

Use these `bootstrap.conf` settings to create the initial node in a system.

#### `/var/opt/ocient/bootstrap.conf` example

YAML

```
initialSystem: true
```

#### Option 2: Bootstrap a new node on a system with an initial node

Use these `bootstrap.conf` settings to create another node in a system, replacing the IP Address `10.10.10.10` with the IP address or hostname of the initial node.

**`/var/opt/ocient/bootstrap.conf` example (recommended)**

YAML

```yaml
adminHost: 10.10.10.10
nodeToken: <token_from_GET_NODE_TOKEN>
```

Generate the token value by executing the `GET NODE TOKEN` SQL statement on an existing node.

> You can also use `adminUserName` and `adminPassword` instead of `nodeToken`, but this approach is deprecated. Use node tokens for improved security.

### 3 Start the Node

Start the database.

Shell

```
sudo systemctl start rolehostd
```

Verify that the node and the service are active by running this status command.

Shell

```
systemctl status rolehostd

rolehostd.service - Rolehostd daemon startup
     Loaded: loaded (/etc/systemd/system/rolehostd.service; enabled; vendor p
     Active: active (running) since Wed 2022-01-26 23:31:36 UTC; 7s ago
     ...
```

You have bootstrapped the node.

## Supported Options

You can edit the `/var/opt/ocient/bootstrap.conf` file to include a number of other options for advanced system configurations.

The Ocient `bootstrap.conf` file can also include these optional parameters. For examples of these options, see the **Example bootstrap.conf file**.

| Option | Description |
|---|---|
| `name` | The default name of the node in the database is the hostname. If that name is not appropriate, you can assign a different name. |
| `nodeAddress` | The default address of this node is the hostname of the node, or the IP address if the `useDns` setting is `false`. If the system has multiple interfaces or you want an alternative setup, then you can specify the node address. This address is the address that all the other nodes in the cluster use to contact this node. |
| `externalAddress` | It might be desirable to have the SQL Nodes listen on a different external address than the system uses internally. The `externalAddress` parameter can either be a single address or a list of addresses.<br>Example of single address:<br>`externalAddress: 10.10.10.1`<br>Example of a list of addresses:<br>`externalAddress: ["10.10.10.1","20.20.20.2"]`<br>ℹThis option applies to REST endpoints only. For REST endpoints, see **System Information REST Endpoints**. |
| `nodeToken` | A single-use token for authenticating the node to the cluster during bootstrap. Generate this value with `GET NODE TOKEN` on any existing node. When you set this parameter, the system authenticates the joining node without requiring administrator credentials. After a successful bootstrap, the system overwrites the token value in `bootstrap.conf` with `REDACTED` and then renames the file to `bootstrap.completed`, so the plaintext secret never persists on disk. If the redaction fails, the system deletes `bootstrap.conf` outright instead of preserving it. The rewrite performs a YAML round-trip, so the system does not preserve any comments from the original file. For details, see **GET NODE TOKEN**. |
| `adminUserName` | **Deprecated.** The default user, specified as `admin@system`, when you create an Ocient System. If a different administrator user should be used to add this node to an existing system, use this option to indicate the user. Use `nodeToken` instead when possible. |
| `adminPassword` | **Deprecated.** If the administrator password is not the default, then use this option to specify the password. Use `nodeToken` instead when possible. |
| `logLevel` | The logging level for the system. Defaults to DEBUG. |
| `connectivityPools` | The configuration of SQL Nodes in a connectivity pool. You can use this configuration to configure the connectivity pool for the first SQL Node in a |

| Option | Description |
| --- | --- |
| | cluster. Other nodes cannot use this option.<br>If there are no entries in the `bootstrap.conf` file, then the Ocient System adds the SQL Node to a new connectivity pool with a default name.<br>Example of the connectivity pool named `test_pool` configuration:<br><br>connectivityPools:<br>test_pool:<br>sourceAddress: 1.2.3.4/12<br>sourcePort: 1 # optional<br>priority: 1<br>listenAddress: 111.1.1.1<br>listenPort: 4050<br>advertisedAddress: localhost<br>advertisedPort: 4050 # optional |
| `systemStorageSpace` | The configuration for storage space has width and parity width for the Ocient System. If you do not configure the storage space, the system sets the width to 3 and parity to 2, the default values. For details about width and parity width, see **Core Elements of an Ocient System**. To set these options using SQL syntax, see **CREATE STORAGESPACE**. |
| `useOpal` | When you set this value to `false`, this option prevents the `rolehostd` service from taking ownership of and enabling Opal locking on all NVMe drives that support it. Bootstrap with this setting using an external Key Management System (KMS). |
| `pageReplication` | The number of page replicas the system writes before a page is available, unless you enable **degraded loading**. The fault tolerance is `(pageReplication - 1)`. The calculation for the default value is `min(width, parityWidth+1)`. For the system storage space, the default value is 3. |

## Example bootstrap.conf File

This example shows a `bootstrap.conf` file that you can use as a template.

YAML

```
## initialSystem: true           # Uncomment for the first node in a
                                 # multi-cluster system.
                                 # Defaults to false. Cannot be
                                 # true if initialSingleClusterSystem
                                 # is also true.

## initialSingleClusterSystem: true  # Uncomment for the first node in a
                                 # single-cluster system.
                                 # Defaults to false. Cannot be
                                 # true if initialSystem is also true.

## systemName: productionSystem  # The name of the Ocient System. This
                                 # configuration applies only when the
                                 # initialSystem or initialSingleClusterSystem
                                 # configuration is set to true.

## adminHost: sql.example.com    # Hostname or IP address of an administrator
                                 # node, generally the first node. Not
                                 # required for the initial node, but required
                                 # for all other nodes.

## name: elmo                    # The name of this node.
                                 # Defaults to hostname.

## nodeAddress: sql1.example.com # The Hostname or IP address of this node.
                                 # Defaults to hostname, and if that does not
                                 # work, the bootstrapping process uses the IP
                                 # address of the system.

## externalAddress: ["10.10.10.1", "20.20.20.2"]

## useDns: false                 # Use DNS to determine the hostname of this
                                 # node. Defaults to true. When you set this
                                 # configuration to false, the bootstrapping
                                 # process uses the IP address of the system.

## nodeToken: <token>            # A single-use bootstrap token generated
                                 # by GET NODE TOKEN. Preferred over
                                 # adminUserName/adminPassword.

## adminUserName: bert@system    # Deprecated. A system administrator username.
                                 # Defaults to "admin@system".
```

```
## adminPassword: ernie          # Deprecated. The password for the
                                 # administrator user. Defaults to "admin".

## logLevel: info               # Log level for the system.
                                 # Defaults to debug.

## connectivityPools:           # Define connectivity pool named test_pool.
##    test_pool:
##      sourceAddress: 1.2.3.4/12 # The source IP address, which is
                                 # the IP address in CIDR notation of

# Amazon Web Services Ocient Installation

Install and deploy an Ocient System on Amazon Web Services (AWS), including EC2 instance selection, storage configuration, and networking for cloud workloads.

This guide explains how to install an Ocient® System in Amazon® Web Services℠ (AWS℠).

For details about AWS concepts, see these pages:

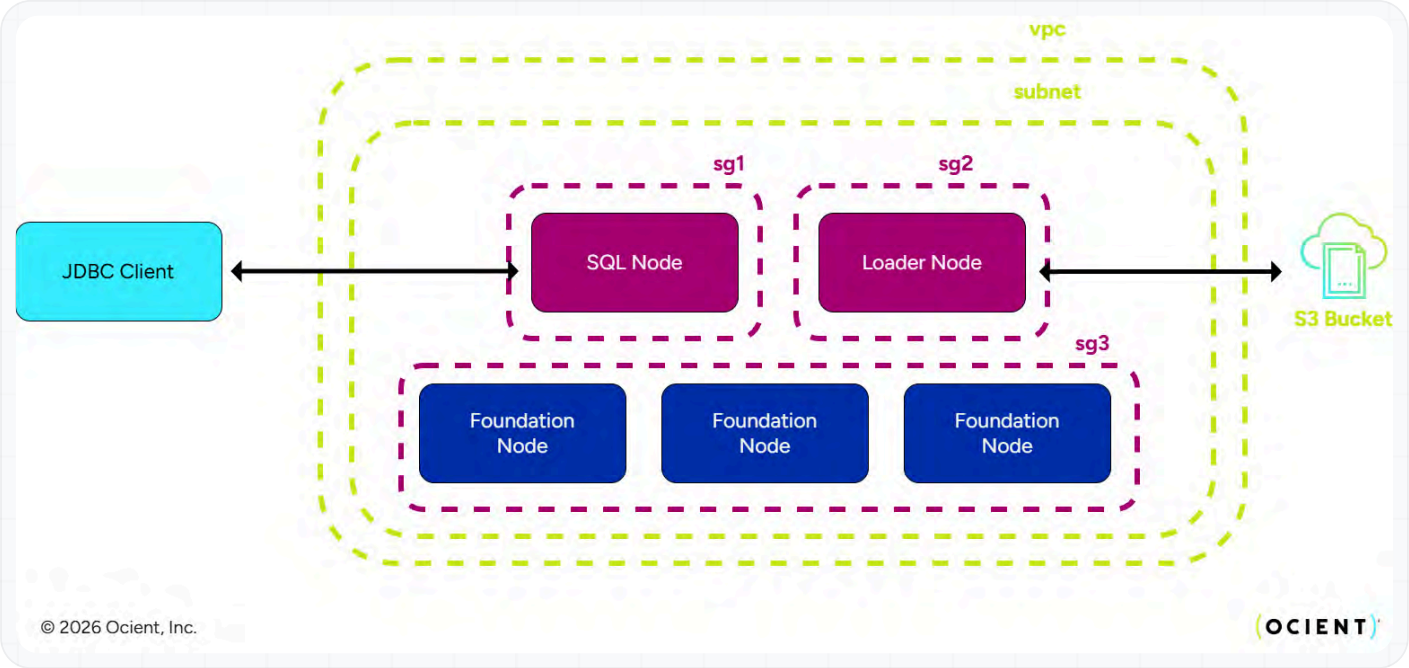
- **What is Amazon EC2?**
- **What is IAM?**
- **A Primer for Amazon Networking - VPC, Availability Zones & Subnets**

Ocient supports deployment in AWS for pilot or testing purposes, but this setup does not guarantee data durability. Stopping Amazon® EC2℠ instances can result in permanent data loss.

The steps for deploying an Ocient System in AWS are:

1. Prepare AWS resources.
2. Set up an initial instance.
3. Create Amazon Machine Images (AMI) from the initial instance.
4. Launch other instances.
5. Follow the standard Ocient installation procedure.

## Example Configuration



The table below shows the recommended instance types for each node type.

| Node Type | Instance Type |
|---|---|
| Foundation Nodes (3) | i3en.metal, i7ie.metal |
| Loader Nodes (1) | i3en.metal, i7ie.metal |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Node Type | Instance Type |
| --- | --- |
| SQL Nodes (1) | r5dn.metal, r6idn.metal |

This diagram shows an example of an Ocient cluster in AWS. The EC2 nodes (SQL, Loader, and Foundation) are deployed within a single subnet of an Amazon Virtual Private Cloud℠ (VPC). AWS assigns each type of node to a separate security group ( `sg1` , `sg2` , `sg3` ).

# Prepare AWS Resources

Create and configure these AWS resources:

- The VPC and subnets for the Ocient System.
- Security groups to access the endpoints for each node type. For details about the network security configuration, see the **Ocient Security Guide**.
- Identity and Access Management (IAM) roles.

If you are loading data from S3, the loader nodes require IAM access to an S3 bucket.

# Node Setup (SQL Role) for Initial Instance

### 1 Launch Instance

Use this configuration for your AMI. Configuration steps differ depending on whether your setup uses a single-volume or multi-volume AMI.

## Operating System (OS)

To set up the AMI, you can use any Ocient-supported OS (see **Ocient System Requirements**).

### Single-Volume AMI

If you use a single-volume AMI, specify this configuration:

- Increase the root volume to 128GB or more.

### Multi-Volume AMI

If you use a multi-volume AMI (e.g., CIS hardened Red Hat® Enterprise Linux® (RHEL®) (RHEL) 9), use this configuration:

- Increase root volume to 30GB or more.
- Increase Elastic Block Store (EBS) volume to 100GB or more.

> This EBS volume supports key system directories in the image ( `/home` , `/var` , `/var/log` , `/var/log/audit` , `/var/tmp` ).

### Instance Type

Use r5dn.metal or a similar instance type.

### Security Group

Use one or more security groups with these rules:

- Allow SSH to the nodes.
- Allow communication internally between nodes.
- Allow access to SQL Node endpoints described in the **Ocient Security Guide**.

## 2 Access Shell

Connect to your instance using Secure Shell (SSH). For details, see **Connect to your Linux instance using an SSH client**.

### 3 Extend Logical Volume Manager (LVM) Volumes (Multi-Volume AMI Only)

> This step applies only to multi-volume AMIs. If you are using a single-volume instance, skip this step.

If you use a multi-volume manager, extend the `/home` and `/var` LVM volumes and their file systems to fill up the expanded EBS volumes. These actions expand the LVM volume and the contained file system to accommodate the Ocient package, logging, and metadata.

These code examples show how to extend LVM volumes for a CIS RHEL 9 image.

> Other AMI types might require different sizing. Contact Ocient support for the best sizing for your system for multi-volume instances.

#### Example

Resize the physical volumes of two drives to use their full capacity after expanding them (see Step 1).

Shell

```
sudo pvresize /dev/nvme0n1
sudo pvresize /dev/nvme1n1
```

Extend local volumes:

- Add 66 percent of the available free space in `vg-01` to the `var_vol` logical volume.
- Add all (100 percent) of the remaining free space in `vg-01` to the `home_vol` logical volume.

Shell

```
sudo lvextend -l +66%FREE /dev/vg-01/var_vol
sudo lvextend -l +100%FREE /dev/vg-01/home_vol
```

Extend the file system to use all available space on its underlying logical volume.

Shell

```
sudo xfs_growfs /home
sudo xfs_growfs /var
```

### 4 Update Packages

Update all your software packages to their latest versions and then reboot your instance.

For RHEL-compatible systems, use this command.

Shell

```
sudo dnf update
```

For Debian®-compatible systems, use this command.

Shell

```
sudo apt update
```

Reboot after the update.

Shell

```
sudo reboot
```

### 5 Install the Ocient Package

Copy over the `ocient` RPM or DEB package and install it.

For RHEL-compatible systems, use this command.

```shell
sudo dnf install ./ocient-RELEASE-XX.X.X-xxxxxxxxxxxxxx-x86_64.rpm
```

For Debian-compatible systems, use this command.

```shell
sudo apt install ./ocient-RELEASE-XX.X.X-xxxxxxxx.xxxxxx-xxxxxxxxxxxx-amd64.d
```

### 6 Set Up Kernel Parameters

Use the `ockernelparams` utility to set up kernel parameters automatically, including the huge pages configuration. Repeat this step on other nodes.

```shell
sudo /opt/ocient/scripts/ockernelparams --node-role sql
```

Reboot the system for the parameters to take effect.

```shell
sudo reboot
```

Check that the local storage drive is attached to the `uio` or `vfio` driver after reboot (the Ocient package installs a service that runs on startup to do this).

```shell
sudo /opt/ocient/scripts/nvme-driver-util.sh
```

For examples of attaching drivers to the NVMe drives, see **NVMe Drive Firmware Upgrade Process**.

### 7 Configure the Firewall

> If you are not using an OS-level firewall, skip this step.

If your base AMI includes a system firewall, you must configure rules that explicitly allow required network communication for your Ocient deployment. For details, see **Ocient Security Guide**.

Required OS firewall rules:

- Allow all necessary ports and protocols between Ocient nodes by:
  - Opening all TCP/UDP ports within the private network range (e.g., `10.0.0.0/16`).
  - Or, allowing known Ocient ports.
- Allow external access where needed by:
  - Enabling SSH access (port 22) from your administrator IP range.
  - Allowing client access to SQL endpoints (for example, port 13101 or as specified in your setup).
  - Opening any additional ports required for monitoring or management tools.

For a list of required ports, see **Network Exposure and Firewall**.

## Create AMI

After your initial node is fully configured, you must replicate the setup process for the remaining nodes in your cluster. This action ensures consistency and allows for proper internal communication between nodes.

For details about creating an AMI, see **Creating an AMI from an Amazon EC2 Instance**.

© 2026 Ocient, Inc

# Set Up Remaining Nodes to Launch the Remaining Instances

Go through this process for each of your remaining nodes.

### 1 Set Up Parameters

Launch the remaining instances with these parameters:

- AMI — Use the AMI created in the **Node Setup (SQL Role) for Initial Instance** step.
- Instance Type — Use `i3en.metal` or an equivalent instance that:
  - Offers local NVMe SSDs for high-performance local storage.
  - Has high throughput and network bandwidth for internal cluster communication.
- Security groups — Ensure these security rules are in place in the AWS security groups associated with the nodes:
  - Allow SSH to the nodes.
  - Allow internal communication between all Ocient nodes.
  - Allow access to endpoints described in the **Ocient Security Guide**.

### 2 Access Shell

Connect to your instance using Secure Shell (SSH). For details, see **Connect to your Linux instance using an SSH client**.

### 3 Set Up Kernel Parameters

Use the `ockernelparams` utility to set up kernel parameters automatically, including the `hugepages` parameters.

This example specifies a Foundation Node `foundation`. Use a different node type as necessary.

```shell
sudo /opt/ocient/scripts/ockernelparams --node-role foundation
```

## Bootstrap the Ocient System

Complete the bootstrapping process for your Ocient System. For details, see **Node Bootstrapping Reference**.

# Google Cloud Platform Ocient Installation

Set up an Ocient system on Google Cloud Platform, utilizing cloud infrastructure for scalable and efficient data warehousing.

This guide explains how to install an Ocient® System in Google® Cloud™ (GCP).

For details about GCP concepts, see these pages:

- **What is Compute Engine?**
- **What is IAM?**
- **VPC Network Overview**

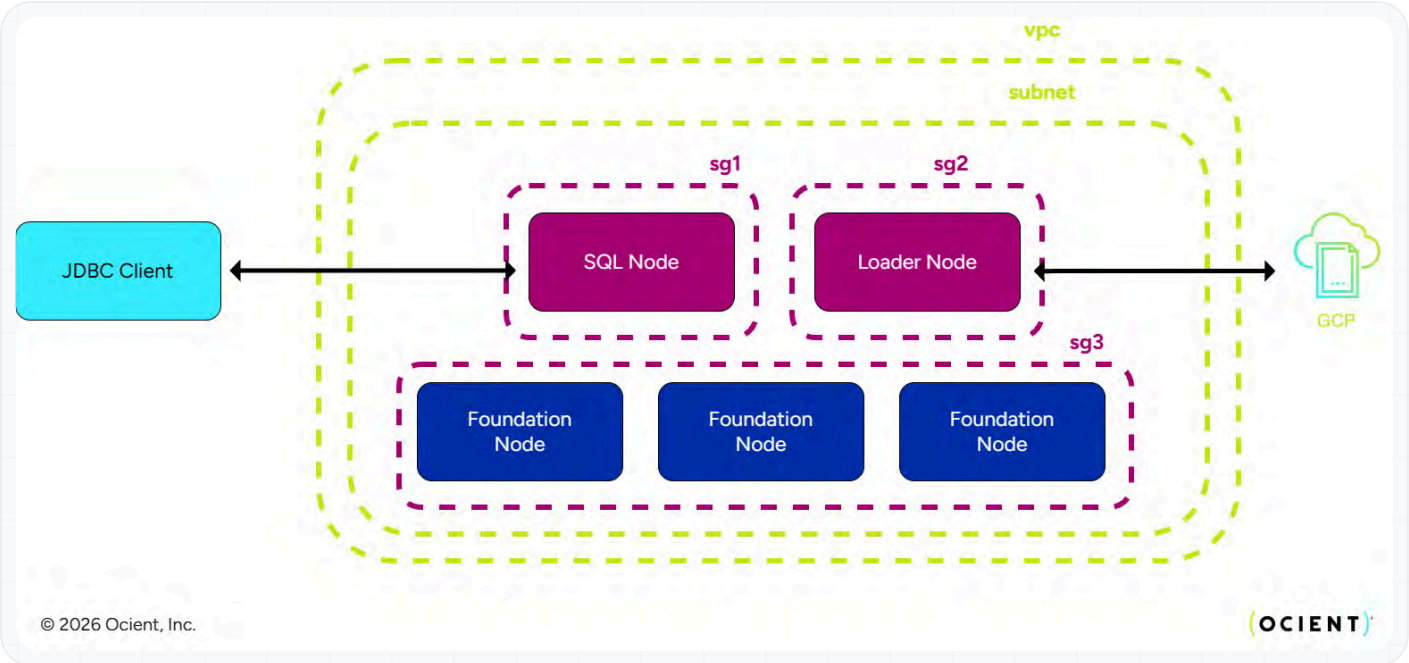
> Ocient supports deployment in GCP for pilot or testing purposes, but this setup does not guarantee data durability. Stopping Compute Engine virtual machine (VM) instances can result in permanent data loss.

The steps for deploying an Ocient System in GCP are:

1. Prepare GCP resources.
2. Set up an initial instance.
3. Create machine images from the initial instance.
4. Launch other instances.
5. Follow the standard Ocient installation procedure.

## Example Configuration

The table below shows the recommended VM types for each node type.



© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Node Type | VM Type |
|---|---|
| Foundation Nodes (3) | z3-highmem-88 |
| Loader Nodes (1) | z3-highmem-88 |
| SQL Nodes (1) | z3-highmem-88 |

Metadata and non-Ocient nodes use the n2-standard-X machine type, where X represents the number of Virtual Central Processing Units (vCPUs) for your workload.

> ⚠ Ocient is deprecating the N2 instance family (e.g., `n2-highmem-96`) for its workloads. Existing N2 deployments continue to function, but new deployments should use Z3 instances.

This diagram shows an example of an Ocient cluster in GCP. The system deploys the Compute Engine VMs (SQL, Loader, and Foundation) within a single subnet of a Virtual Private Cloud (VPC). GCP uses VPC firewall rules and network tags to control traffic to each node type.

## Prepare GCP Resources

Create and configure these GCP resources:

- The VPC network and subnets for the Ocient System. For details, see **Create and manage VPC networks**.

- VPC firewall rules with network tags to control access to the endpoints for each node type. For details about firewall configuration, see **Create firewall rules** and **Add and remove network tags**. For details about the network security configuration, see the **Ocient Security Guide**.
- Identity and Access Management (IAM) roles. For details, see **Grant an IAM role**.

> If you are loading data from Cloud Storage, the Loader Nodes require IAM access to a Cloud Storage bucket. Assign the `roles/storage.objectViewer` role (or `roles/storage.objectAdmin` if you also need write access) to the service account used by the Loader Node VMs.

# Node Setup (SQL Role) for the Initial Instance

### 1 Launch the Instance

Use this configuration for your machine image. Configuration steps differ depending on whether your setup uses a single-volume or multi-volume machine image. For details about creating instances, see **Create and start a Compute Engine instance**.

## Operating System (OS)

To set up the machine image, you can use any Ocient-supported OS (see **Ocient System Requirements**).

#### Single-Volume Machine Image

If you use a single-volume machine image, specify this configuration:

- Increase the boot disk to 128GB or more.

#### Multi-Volume Machine Image

If you use a multi-volume machine image (e.g., CIS hardened Red Hat® Enterprise Linux® (RHEL®) (RHEL) 9), use this configuration:

- Increase the boot disk to 30GB or more.

- Increase the additional Persistent Disk volume to 100GB or more. For details, see **Add a Persistent Disk to your VM**.

> This Persistent Disk volume supports key system directories in the image ( `/home` , `/var` , `/var/log` , `/var/log/audit` , `/var/tmp` ).

#### VM Type

Use `z3-highmem-88` for Ocient nodes. Use `n2-standard-X` for Metadata and non-Ocient nodes.

#### Secure Boot

Disable Shielded VM secure boot when creating the instance. Use the `--no-shielded-secure-boot` flag with the `gcloud` command.

Shell

```
gcloud compute instances create INSTANCE_NAME \
    --no-shielded-secure-boot
```

If you are using the Console, uncheck **Turn on Secure Boot** under **Security > Shielded VM**. For details, see **Shielded VM**.

#### Firewall Rules and Network Tags

Create VPC firewall rules with network tags that enforce these rules:

- Allow SSH to the nodes.
- Allow communication internally between nodes.
- Allow access to SQL Node endpoints. For details, see the **Ocient Security Guide**.

Assign the appropriate network tags to each VM so that the firewall rules apply to the correct node types. For details, see **Create firewall rules** and **Add and remove network tags**.

### 2 Access the Shell

Connect to your instance using Secure Shell (SSH). For details, see **Connect to Linux VMs using Google tools**.

### 3 Extend Logical Volume Manager (LVM) Volumes (Multi-Volume Machine Image Only)

> This step applies only to multi-volume machine images. If you are using a single-volume instance, skip this step.

If you use a multi-volume manager, extend the `/home` and `/var` LVM volumes and their filesystems to fill up the expanded Persistent Disk volumes. These actions expand the LVM volume and the contained file system to accommodate the package, logging, and metadata of the Ocient System.

These code examples show how to extend LVM volumes for a RHEL 9 image.

> Other machine image types might require different sizing. Contact Ocient support for the best sizing for your system for multi-volume instances.

#### Examples

Resize the physical volumes of two drives to use their full capacity after expanding them (see **Prepare GCP Resources**).

Shell

```
sudo pvresize /dev/nvme0n1
sudo pvresize /dev/nvme1n1
```

Extend local volumes:

- Add 66 percent of the available free space in `vg-01` to the `var_vol` logical volume.
- Add all (100 percent) of the remaining free space in `vg-01` to the `home_vol` logical volume.

Shell

```
sudo lvextend -l +66%FREE /dev/vg-01/var_vol
sudo lvextend -l +100%FREE /dev/vg-01/home_vol
```

Extend the file system to use all available space on its underlying logical volume.

Shell

```
sudo xfs_growfs /home
sudo xfs_growfs /var
```

### 4 Update Packages

Update all your software packages to their latest versions and then reboot your instance.

For RHEL-compatible systems, use this command.

Shell

```
sudo dnf update
```

For Debian®-compatible systems, use this command.

Shell

```
sudo apt update
```

Reboot after the update.

Shell

```
sudo reboot
```

### 5 Install GCP Kernel Modules

© 2026 Ocient, Inc

GCP Compute Engine VMs require additional kernel modules for full hardware support. Install the extra kernel modules package that matches your running kernel version.

Shell

```
sudo apt install linux-modules-extra-$(uname -r)
```

Reboot the node after the installation completes.

Shell

```
sudo reboot
```

> This step is required for GCP Compute Engine VMs. Without the extra kernel modules, certain hardware drivers and features might not function correctly.

## 6 Install the Ocient Package

Copy over the `ocient` RPM or DEB package and install it.

For RHEL-compatible systems, use this command.

Shell

```
sudo dnf install ./ocient-RELEASE-XX.X.X-xxxxxxxxxxxxxx-x86_64.rpm
```

For Debian-compatible systems, use this command.

Shell

```
sudo apt install ./ocient-RELEASE-XX.X.X-xxxxxxxx.xxxxxx-xxxxxxxxxxxx-amd64.d
```

## 7 Set Up Kernel Parameters

Use the `ockernelparams` utility to set up kernel parameters automatically, including the huge pages configuration. Repeat this step on other nodes.

Shell

```
sudo /opt/ocient/scripts/ockernelparams --node-role sql
```

Reboot the system for the parameters to take effect.

Shell

```
sudo reboot
```

Check that the local storage drive is attached to the `uio` or `vfio` driver after reboot (the Ocient package installs a service that runs on startup to perform this action).

Shell

```
sudo /opt/ocient/scripts/nvme-driver-util.sh
```

On GCP, drives bound to the `uio_pci_generic` driver display without a device name. This behavior is expected for GCP NVMe drives.

```
NVMe device status

BDF             Numa Node       Driver name             Device name
0000:00:04.0    -1              uio_pci_generic         -
```

For examples of attaching drivers to the NVMe drives, see **NVMe Drive Firmware Upgrade Process**.

## 8 Configure the Firewall

If you are not using an OS-level firewall, skip this step.

If your base machine image includes a system firewall, you must configure rules that explicitly allow required network communication for your Ocient deployment. For details, see the **Ocient Security Guide**.

Required OS firewall rules:

- Allow all necessary ports and protocols between Ocient nodes by:
  - Opening all TCP/UDP ports within the private network range (e.g., `10.0.0.0/16`), or allowing known Ocient ports.
- Allow external access where needed by:
  - Enabling SSH access (port `22`) from your administrator IP range.
  - Allowing client access to SQL endpoints (for example, port `13101` or as specified in your setup).
  - Opening any additional ports required for monitoring or management tools.

For a list of required ports, see **Network Exposure and Firewall**.

> In addition to OS-level firewall rules, ensure that your GCP VPC firewall rules and network tags are properly configured (see **Prepare GCP Resources**). Both layers must allow the required traffic for the Ocient System to function correctly.

## Create the Machine Image

After your initial node is fully configured, you must replicate the setup process for the remaining nodes in your cluster. This action ensures consistency and allows for proper internal communication between nodes.

For details about creating a machine image, see **Create a machine image**.

## Set Up Remaining Nodes to Launch the Remaining Instances

Go through this process for each of your remaining nodes.

### 1 Set Up Parameters

Launch the remaining instances with these parameters. For details, see **Create an instance from a machine image**.

- Machine image — Use the machine image created in the **Node Setup (SQL Role) for Initial Instance** step.
- VM type — Use `z3-highmem-88` for Ocient nodes. This VM type:
  - Provides sufficient memory and compute for high-performance Ocient workloads.
  - Has high throughput and network bandwidth for internal cluster communication.
- Secure boot — Disable secure boot using the `--no-shielded-secure-boot` flag.
- VPC firewall rules — Ensure these rules are in place using network tags associated with the nodes:
  - Allow SSH to the nodes.
  - Allow internal communication between all Ocient nodes.
  - Allow access to endpoints described in the **Ocient Security Guide**.

### 2 Access the Shell

Connect to your instance using SSH. For details, see **Connect to Linux VMs using Google tools**.

### 3 Set Up Kernel Parameters

Use the `ockernelparams` utility to automatically set up kernel parameters, including the `hugepages` parameters.

This example specifies a Foundation Node `foundation`. Use a different node type as necessary.

Shell

```
sudo /opt/ocient/scripts/ockernelparams --node-role foundation
```

Reboot the system for the parameters to take effect.

```shell
sudo reboot
```

## Bootstrap the Ocient System

Complete the bootstrapping process for your Ocient System. For details, see **Node Bootstrapping Reference**.

# Configure Storage Spaces

Configure storage spaces in an Ocient System, including segment group width, parity width, and overprovisioning for fault tolerance and capacity planning.

When setting up an Ocient® System, a storage cluster represents a set of Foundation Nodes in the system. A storage space is a set of parameters that defines how data and fault tolerance are administered across the storage clusters that reference it. Multiple storage clusters can share the same storage space, but each cluster belongs to only one storage space.

Creating a storage space is an important step for launching an Ocient System that must be done after installing hardware and bootstrapping nodes, but before you start loading and querying data. To see how creating a storage space fits into the Ocient installation process, see **Ocient Application Configuration**.

This tutorial explains how to set up and configure storage spaces to meet the needs of your Ocient System.

When an Ocient System starts, the system automatically creates a default system storage space for persistent metadata, such as system catalog tables. This default storage space is immutable, meaning you cannot delete or modify it.

The name of the metadata storage space is `systemStorageSpace` in the **sys.storage_spaces** system catalog table.

# User-Defined Storage Spaces

For storage other than metadata, you must create one or more separate storage spaces. The creation of storage spaces is necessary before loading data or performing other operations. User-defined storage spaces are configurable for extra resiliency or storage based on your system needs.

A storage space represents how the storage cluster spreads data across Foundation Nodes to balance storage and fault tolerance. In general terms, the storage cluster configuration defines how the storage cluster behaves for these attributes:

- Regular data storage operations (see **Segment Group Width**)
- Query resiliency (see **Parity Width**)
- Load resiliency (see **Overprovision**)

You can configure a storage space to assign nodes to these job roles by using DDL statements (see **CREATE STORAGESPACE**).

Planning out your storage space carefully is important because you cannot change a storage space configuration after creation.

## Segment Group Width

Storage space parameter: `WIDTH`

The Segment Group Width determines the number of segments that comprise a segment group. Functionally, this setting defines how many Foundation Nodes perform read and write operations for a segment group.

Within a Segment Group, the system assigns each segment to a different node. Hence, the Segment Group Width cannot exceed the number of nodes in your system.

In most circumstances, Segment Group Width should comprise most of your Foundation Nodes. On system startup, the default Segment Group Width is three, which is the minimum number of nodes required for an Ocient System.

## Parity Width

Storage space parameter: `PARITY_WIDTH`

You can assign a subset of the Segment Group Width to Parity Width.

The Parity Width of a storage space determines its fault tolerance, defining the number of parity coding bits to use for each segment group. This number determines how many nodes can fail before the cluster is disabled.

Parity Width protects system querying capabilities. If any nodes fail, the system can execute and complete queries as long as the number of failed nodes is less than or equal to the Parity Width. When deployed in conjunction with overprovisioned nodes, Parity Width also provides fault tolerance for loading operations.

The `PARITY WIDTH` requires additional storage overhead, which is calculated by the formula `(PARITY WIDTH) / (SEGMENT GROUP WIDTH - PARITY WIDTH)`.

## Overprovision

The Ocient System overprovisions any Foundation Nodes in the cluster in excess of the Segment Group Width by default. These nodes can include any nodes not configured in the storage space or any nodes added later.

Overprovisioned nodes protect loading operations from node failure, although they must be used in conjunction with Parity Width. In the event of node failures, loading operations can continue as long as the number of failed nodes does not exceed the Parity Width nodes or the number of overprovisioned nodes. For this reason, providing fault tolerance for loading requires a balance of Parity Width and overprovisioned nodes.

Unlike Segment Group Width and Parity Width, you do not explicitly define a value for overprovisioning. Instead, any Foundation Nodes in the cluster in excess of the number allocated toward Segment Group Width or Parity Width become overprovisioned by default.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

⚠ Avoid configuring a storage space where the Segment Group Width is significantly smaller than the total number of nodes in the cluster. Each additional overprovisioned node increases the storage metadata overhead on the system, which can degrade stability as total data volume grows. As a best practice, set the Segment Group Width to encompass most of the nodes in the cluster, reserving only a small number of nodes for overprovisioning.

## Degraded Loading

Under normal operation, loading data requires all segments in a segment group to be successfully written across the number of nodes defined by the Segment Group Width. If any target node is unavailable and there are no overprovisioned nodes to absorb the failure, loading fails entirely.

Degraded loading extends the fault tolerance of loading operations beyond what overprovisioning alone provides. When you enable degraded loading, the system can commit a segment group even if some segments cannot be written because nodes are unavailable. The system commits the segment group as long as the number of missing segments does not exceed the Parity Width. In this case, the system records the segment group using the `DAMAGED` state, and the system fills the missing segments with virtual segments that the system can reconstruct later.

This behavior allows loading to continue through node outages without requiring additional overprovisioned nodes, aligning loading resiliency more closely with query resiliency.

### Enable or Disable Degraded Loading

Degraded loading is disabled by default in version 27.0 and earlier of the Ocient System. For a new cluster that you bootstrap in version 28.0, degraded loading is enabled by default. For a migration from a cluster with version 27.0 or later to version 28.0, degraded loading retains its previous value; it is disabled unless you explicitly enabled it before the migration.

Enable degraded loading using the `ALTER SYSTEM ALTER CONFIG SET` SQL statement.

SQL

```
ALTER SYSTEM ALTER CONFIG SET 'lts.allowDegradedWrites' = 'true';
```

Disable degraded loading.

```sql
ALTER SYSTEM ALTER CONFIG SET 'lts.allowDegradedWrites' = 'false';
```

Reset the parameter to its default value.

```sql
ALTER SYSTEM ALTER CONFIG RESET 'lts.allowDegradedWrites';
```

## Rebuild Degraded Segment Groups

Segment groups written in a degraded state remain queryable because the available data and parity information are sufficient to reconstruct the missing segments at the time of query execution. However, the system does not automatically restore degraded segment groups to a fully intact state. After the unavailable nodes come back online, you must manually issue a rebuild task to restore the damaged segment groups.

```sql
CREATE TASK TYPE REBUILD;
```

> ⚠ Until you rebuild degraded segment groups, they have reduced fault tolerance. If additional nodes fail beyond the original missing segments, the segment group might change to the `UNAVAILABLE` state, and data loss might occur. Monitor degraded segment groups and rebuild them as soon as the system restores full cluster connectivity.

## Monitor Degraded Segment Groups

Query the `sys.degraded_segment_groups` system catalog table to identify segment groups in a damaged state. This table shows all segment groups with the `DAMAGED` or `UNAVAILABLE` state, along with the locations of clusters and tables.

```sql
SELECT * FROM sys.degraded_segment_groups;
```

When you enable degraded loading, set up monitoring and alerting on this table to detect when segment groups require rebuilding.

### Limitations

Degraded loading does not remove all limitations related to node outages:

- Query availability is still required for loading. Pipeline loading requires access to the system catalog tables, and CTAS and IAS operations require access to the source tables. If the number of offline nodes exceeds the Parity Width of the relevant storage space, queries fail, and loading also fails regardless of the degraded loading setting.
- Delete operations are independent of degraded loading. Deleting rows from a table requires a strict majority of nodes to be online and query availability (fewer than Parity Width unavailable nodes). In some configurations, a delete operation might fail even though loading can continue in a degraded state.
- Node transitions during loading might cause temporary failures. If a node goes offline while a CTAS or IAS query is in progress, the query might fail because the system cannot guarantee success when the storage cluster configuration changes mid-operation. Execute the query again to resolve this.

## Storage Space Configuration Examples

This section demonstrates different configurations for storage spaces. The examples each go through different scenarios for node failures to show the fault tolerance of each setup.

For information on the syntax for storage spaces, see **CREATE STORAGESPACE**.

### 10-Node Cluster

This example assumes you have a storage cluster of 10 Foundation Nodes.

```SQL
CREATE STORAGESPACE ocient WIDTH = 10, PARITY_WIDTH = 2;
```

- The `WIDTH = 10` parameter means the system stores a segment group on 10 different nodes.
- The `PARITY_WIDTH = 2` parameter means each segment in the group contains enough parity bits to restore lost data for up to two nodes. In effect, this means parity bits comprise 20 percent of storage.

### Tolerance Scenarios

This storage space setup has no overprovisioning, making loading operations less resilient without degraded loading. This setup results in these outcomes if nodes become disabled:

- If one node fails, loading fails, and querying can continue.
- If two nodes fail, loading fails, and querying can continue.
- If three nodes fail, loading and querying both fail.

With **degraded loading** enabled, loading can continue through node failures up to the Parity Width:

- If one node fails, loading continues with data committed in a degraded state, and querying can continue.
- If two nodes fail, loading continues with data committed in a degraded state, and querying can continue.
- If three nodes fail, loading and querying both fail.

## 12-Node Cluster

This example assumes a storage cluster of 12 Foundation Nodes.

```SQL
CREATE STORAGESPACE ocient WIDTH = 10, PARITY_WIDTH = 2;
```

Note that this DDL statement is the same as the **10-Node Cluster Example**, but the cluster in this example has two additional nodes.

- The `WIDTH = 10` parameter means the system stores a segment group on 10 of the 12 nodes.
- The two remaining nodes are overprovisioned.
- The `PARITY_WIDTH = 2` parameter means each segment in the group contains enough parity bits to restore lost data for up to two nodes. In effect, this means parity bits comprise 16.6 percent of storage.

### Tolerance Scenarios

This setup provides a level of resiliency for both querying and loading. The setup results in these outcomes if nodes become disabled:

- If one node fails, loading and querying continues.
- If two nodes fail, loading and querying continues.
- If three nodes fail, loading and querying both fail.

## 12-Node Cluster with More Parity Width

This example assumes a storage cluster of 12 Foundation Nodes with more nodes allocated to parity.

SQL

```
CREATE STORAGESPACE ocient WIDTH = 10, PARITY_WIDTH = 3;
```

- The `WIDTH = 10` parameter means the system stores a segment group on 10 of the 12 nodes.
- The two remaining nodes are overprovisioned.
- The `PARITY_WIDTH = 3` parameter means each segment in the group contains enough parity bits to restore lost data for up to three nodes. In effect, this means parity bits comprise 42 percent of storage.

### Tolerance Scenarios

This setup provides resiliency for loading and especially for querying. The setup results in these outcomes if nodes become disabled:

- If one node fails, both loading and querying continue.
- If two nodes fail, both loading and querying continue.
- If three nodes fail, loading fails, and querying continues.
- If four nodes fail, both loading and querying fail.

With **degraded loading** enabled, loading resiliency extends beyond the overprovisioned node count:

- If one node fails, both loading and querying continue.
- If two nodes fail, both loading and querying continue.
- If three nodes fail, loading continues with data committed in a degraded state, and querying continues.
- If four nodes fail, loading and querying both fail.

## 15-Node Cluster

This example assumes a cluster of 15 Foundation Nodes. The configuration in this setup includes five overprovisioned nodes, exceeding the Parity Width nodes. This number of overprovisioned nodes would be inefficient in a real system and increases storage metadata overhead that can impact stability at scale. However, this example demonstrates what happens if you added extra nodes at a later time to a cluster, which the storage space would recognize as overprovisioned.

SQL

```
CREATE STORAGESPACE ocient WIDTH = 10, PARITY_WIDTH = 3;
```

- The `WIDTH = 10` parameter means the system stores a segment group on 10 of the 15 nodes.
- The five remaining nodes are overprovisioned.
- The `PARITY_WIDTH = 3` parameter means each segment in the group contains enough parity bits to restore lost data for up to three nodes. In effect, this means

parity bits comprise 20 percent of storage.

### Tolerance Scenarios

This setup provides resiliency for both querying and loading, but having more than three overprovisioned nodes provides no benefit because it exceeds three Parity Width nodes.

This setup results in these outcomes if nodes become disabled:

- If one node fails, loading and querying continue.
- If two nodes fail, loading and querying continue.
- If three nodes fail, loading and querying continue.
- If four nodes fail, loading and querying both fail because this breaches the Parity Width tolerance.

# Ocient Software Upgrade

Upgrade Ocient System software with a rolling upgrade procedure that maintains uptime, validates node compatibility, and preserves query availability.

To upgrade the Ocient® software, you must upgrade the DEB or RPM package on each node in the cluster. Versions of the Ocient software must match across the cluster, so upgrades must be done in an all-or-nothing fashion. Contact Ocient Support for assistance with the upgrade process.

ⓘ The Ocient System does not support the downgrade of the software.

⚠ Consult the release notes for the target version. The version might have changes to any of the supported operating systems, the required operating system configuration, or the `rolehostd` configuration.

## Ocient System Prerequisites

- An existing Ocient installation is present on each node in the cluster.
- The RPM or DEB file is locally available on the file system.
- No jobs are running on the Ocient cluster.
- All nodes have stopped the `rolehostd` service. For details about stopping the `rolehostd` service, see the **Startup and Shutdown Procedure**.

## RPM Upgrade

⚠ Consult the documentation of the package manager of your operating system for specific options and command-line syntax.

Use this command to upgrade using an Ocient RPM package from the local file system. Include `./` or specify the full path to the RPM file, otherwise the `dnf` command

© 2026 Ocient, Inc

attempts to search the configured repositories instead of installing the local RPM file. In this example, replace `XX` with the Ocient package version of the provided file.

```shell
sudo dnf install ./ocient-XX-x86_64.rpm
```

After the upgrade is complete, you must run the startup procedures on all nodes. For details, see **Startup and Shutdown Procedure**.

## DEB Upgrade

Use this command to upgrade using an Ocient DEB package from the local file system. Include `./` or specify the full path to the DEB file, otherwise the `apt` command attempts to search the configured repositories instead of installing the local DEB file. In this example, replace `XX` with the Ocient package version of the provided file.

```shell
sudo apt install ./ocient-XX-amd64.deb
```

After the upgrade is complete, you must run the startup procedures on all nodes. For details, see the **Startup and Shutdown Procedure**.

# Maintenance Overview

Overview of routine maintenance tasks in an Ocient System, including software upgrades, hardware replacement, rebuilds, monitoring, and capacity planning.

Ocient® System Administrators need to perform maintenance for three primary reasons:

- When the Ocient software requires action, such as rebuilding lost or damaged segments
- When firmware or OS software updates are required
- When drive, memory, or system hardware failures occur

The maintenance documentation begins with Ocient software-related maintenance and proceeds to hardware-related maintenance.

# Guide to Rebuilding Segments

Step-by-step guide to rebuilding segments in an Ocient System using distributed tasks to restore redundancy after disk replacement or node failure events.

Data in an Ocient® System is erasure coded to provide resilience to disk and Foundation Node failures. The resilience of a system depends on the parity width of the storage space, which represents the number of associated disks (or nodes) that can fail without interruption of service or data loss.

For details about storage spaces and parity width, see **Configure Storage Spaces**.

## Data Segment Statuses

You can check the status of your system segment groups by querying the `sys.segment_groups` system catalog table. For details, see **System Catalog**.

This table describes the states for data segments.

| Status | Description | Recovery Process |
|---|---|---|
| INTACT | The normal and operable status. | No recovery needed. |
| DAMAGED | The segment failed a checksum, meaning the segment data is corrupted and unusable. | If you have sufficient parity width, you can recover a damaged segment by invoking a rebuild segment task. |
| MISSING | The segment is on a node or disk that is currently offline. If the node or disk rejoins the cluster, it can transition to the INTACT status. | When a disk or Foundation Node is permanently removed, you can perform a rebuild task to recover the data. This requires sufficient parity width. |
| REBUILDING | The segment is in recovery after damage or missing segment data. | Recovery is already in progress. |

## Recovery Considerations

If a segment has the DAMAGED or MISSING status, queries can proceed by reconstructing the data on demand using the remaining erasure-coded data in the segment group.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Having a non-INTACT status means that input or output (I/O) performance is significantly reduced.

To restore full performance, you need to run a segment rebuild task. Segment rebuilding is not automatic. The system administrator must manually invoke it.

A segment rebuild fails, and data is lost completely if the number of segments with the DAMAGED status in a segment group exceeds the parity width of the storage space. To avoid data loss:

- Provision the parity width of the storage space at or above the number of expected concurrent node failures.
- Rebuild damaged or permanently missing segments as soon as possible.

## Checking for Abnormal Segments

You can find any segments that need a rebuild by querying for segment groups with an abnormal status.

### Examples

#### Finding Faulty Segment Groups

This example query finds any segment groups with the DAMAGED or MISSING status.

SQL

```sql
SELECT * FROM sys.segment_groups WHERE status IN ('DAMAGED', 'MISSING');
```

*Output*

Text

```
|         "id"         |              "cluster_id"              | "segment_type" |
|----------------------|----------------------------------------|----------------|-
| "720576045199095878" | "074c32ec-4f92-4718-ada1-5eb55eafdcb3" | TKT_SEGMENT    |
| "716072445571725367" | "074c32ec-4f92-4718-ada1-5eb55eafdcb3" | TKT_SEGMENT    |
```

#### Finding Clusters and Nodes with Faulty Segment Groups

Inspect the count of damaged groups by cluster and node.

SQL

```
SELECT
  c.name AS cluster_name,
  n.name AS node_name,
  g.status AS segment_group_status,
  seg.status AS segment_status,
  seg.kind,
  COUNT(*) AS segment_count
FROM
  sys.segment_groups g
LEFT JOIN
  sys.clusters c
  ON c.id = g.cluster_id
LEFT JOIN
  sys.stored_segments seg
  ON seg.segment_group_id = g.id
LEFT JOIN
  sys.nodes n
  ON n.id = seg.node_id
WHERE
  g.status <> 'INTACT'
  AND (seg.status <> 'INTACT' OR seg.status IS NULL)
  GROUP BY 1,2,3,4,5
  ORDER BY 1,2,3,4,5;
```

*Output*

Text

```
|   "cluster_name"   | "node_name" | "segment_group_status" | "segment_status" | "k
|--------------------|-------------|------------------------|------------------|---
| foundation_cluster | foundation0 | DAMAGED                |                  | VI
```

## Starting a Segment Rebuild Task

A user with System Administrator privileges can start a segment rebuild using the `CREATE TASK TYPE REBUILD` SQL statement. You cannot cancel a segment rebuild task after it is started.

Most commonly, a rebuild task repairs all damaged or missing segments across the system.

**Example**

Create a rebuild task.

```
SQL
CREATE TASK TYPE REBUILD;
```

The system can continue to perform queries while rebuilding segments, but the process can impact I/O performance.

### Advanced Rebuild Commands

Rebuild tasks can also execute on specific Foundation Nodes or clusters. For information on fine-tuning rebuild tasks, see **CREATE TASK**.

## Checking Rebuild Task Status

Monitor the status of current and past segment rebuild tasks from the `sys.subtasks` system catalog table. For details, see **System Catalog**.

```
SQL
SELECT * FROM sys.subtasks WHERE task_type = 'rebuild';
```

This table describes the statuses for a rebuild task.

| Status | Status Detail | Description | Next Steps |
|---|---|---|---|
| complete | no_work | The segment groups were already available and healthy. No rebuilding was needed. | None |
| complete | complete | Rebuild completed successfully. | None |
| running | rebuild_in_progress | Rebuild is in process. | You can monitor the progress of the rebuild task by |

| Status | Status Detail | Description | Next Steps |
|---|---|---|---|
| | | | checking the JSON dictionary in the `details` column of the `sys.subtasks` system catalog table. |
| failed | rebuild_not_possible | The number of missing or damaged segments exceeds the parity width, and the data cannot be recovered currently. | If missing segments are available on an offline drive, you can attempt another rebuild task when that drive is made available to the system.<br>Otherwise, you cannot recover the data. |
| failed | rebuild_no_space | There is not enough space available to rebuild the segment. | You can complete the rebuild by truncating other data to free up space. |
| failed | failed_on_node | The cluster lost its connection to the node before the rebuild was completed. | This is a transient error. You can retry the rebuild task. |
| failed | error | An unexpected internal error occurred. | Review error message details using the `rolehostd` logs. For details, see **Log Monitoring**. |

# Startup and Shutdown Procedure

Startup and shutdown procedures for an Ocient System that preserve data integrity, drain queries cleanly, and bring services online in the correct order.

Ocient® operates as a distributed system, so properly shutting down the system and preventing sudden power loss to nodes is important to ensure data integrity is maintained.

Execution of this process requires System Administrator access to the database and `sudo` privilege on the node being started or shut down. This procedure is not applicable to fully managed Ocient Systems.

## Startup Procedure

The startup procedure can be used for starting the `rolehostd` process on a running node as well as powering on nodes in an Ocient System. In most installations, the `rolehostd` process is configured to automatically start on system boot up.

The `rolehostd` process is the main executable for an Ocient System. During the startup of the `rolehostd` process, every non-Admininistrator Node reaches out to one of the Administrator Nodes. These nodes require a “quorum” for the Ocient System to startup and operate. To establish a quorum, a majority of Administrator Nodes must be actively running the `rolehostd` process. For example, when an Ocient System has three Administrator Nodes, at least two must be active to establish quorum and service requests from other nodes.

Nodes in an Ocient System should started in the following sequence for smoothest operation:

> ⓘ Queries are not completed until Foundation Nodes are online.

1. Start the `rolehostd` process on all dedicated **Administrator Nodes** and **SQL Nodes** using the `systemctl start rolehostd` command.
2. Start the `rolehostd` process on all **Foundation Nodes** using the `systemctl start rolehostd` command.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

3. Start the `rolehostd` process on all **Loader Nodes** using the `systemctl start rolehostd` command.
4. After the `rolehostd` process has finished starting on all Loader Nodes, start the Loading and Transformation service using the `systemctl start lat` command.

## Shutdown Procedure

The shutdown procedure can be used for stopping the `rolehostd` process as well as powering off nodes in the Ocient System.

Properly sequencing the shutdown of nodes in an Ocient System ensures a smooth power-down process and reduces the appearance of errors to users in loading and querying as the system goes offline. The `rolehostd` process must be running on nodes with the Administrator Role for Global Dictionary Compression (GDC) lookup to work during loading and querying of data. If these nodes are shut down first, this causes GDC lookups to fail, resulting in failures for both loading and querying of data.

It is recommended to stagger powering on of nodes by few seconds to reduce the surge in power distribution circuits.

When you execute `systemctl kill -s SIGKILL rolehostd`, the Ocient System sends `SIGKILL` to the `rolehostd` process. The node stops immediately without waiting for any queries or loading that are active on the node to finish. Some potential errors might be visible to the user. To avoid the errors, use the *quiescing* process.

The Ocient System should be stopped in the following sequence:

1. Stop the Loading and Transformation service on all Loader Nodes using the `systemctl stop lat` command.
2. Stop the `rolehostd` process on all Loader Nodes the `systemctl kill -s SIGKILL rolehostd` command.
3. Stop the `rolehostd` process on all Foundation Nodes the `systemctl kill -s SIGKILL rolehostd` command. Any queries issued after this point fail.
4. Stop the `rolehostd` process on all SQL Nodes using the `systemctl kill -s SIGKILL rolehostd` command.
5. Stop the `rolehostd` process on all Administrator Nodes the `systemctl kill -s SIGKILL rolehostd` command.

© 2026 Ocient, Inc

# Quiescing Nodes

Quiescing nodes can be used for gracefully stopping the `rolehostd` process without interrupting loading or running queries. This process is most useful for maintenance purposes or for node upgrades. *Quiescing* refers to the graceful shutdown of a node, whereas *quiesced* refers to a node that has completed quiescing and is now fully shut down.

After the node shuts down, quiescing nodes stop interacting with the rest of the system. Only quiesce one node at a time. When you quiesce multiple nodes at the same time, the quiesce process can freeze or lose forward progress for queries and loading. At startup, the node automatically rejoins the system and participates normally.

To issue a quiesce, execute `systemctl stop rolehostd`. This command sends the `SIGTERM` signal to the `rolehostd` process. The node begins the quiesce process, waits for all relevant queries or loading to finish, and shuts down. If a long-running query causes the quiesce to freeze, kill the query to finish the quiesce process.

During the quiesce process, a SQL Node continues to accept new connections from clients, such as JDBC or pyocient. However, when these clients execute queries, EXPLAIN statements, or DDL updates, the Ocient System redirects the clients to another online SQL Node, if one exists. A user might connect or run a query with the `force` option, which overrides the redirect behavior and forces the command to run on the SQL Node in the quiesce process. In this case, the Ocient System does not guarantee the successful completion of the query.

A Foundation Node in the quiesce process waits for any segment rebuilds that are in progress to finish. When you interrupt or fail the rebuild, the quiesce process finishes shortly.

When a Loader Node is in the middle of loading, and you initiate the quiesce process on this node, stop the Loading and Transform (LAT) service that is on the same node.

Quiesce has a default time limit of 30 minutes, controlled by the `systemd` service. After a node quiesces for 30 minutes, the `systemd` service sends the `SIGKILL` signal to `rolehostd` and forcefully kills the node. To change this timeout, edit the `TimeoutStopSec` parameter in the `rolehostd` `systemd` service file.

# Power Safety Recommendations

Power safety recommendations for Ocient hardware deployments, including UPS, redundant power supplies, and safe shutdown procedures to prevent data corruption.

Like any distributed data processing system, power safety in Ocient® is important to ensure data integrity. Data integrity in Ocient comprises newly loaded data that is in the process of being written to storage and metadata files that contain information about the state of the system.

Ensure that you have Power Loss Protection included in the NVMe drives. The Ocient System does provide some protection against power loss. So, follow these best practices for power management.

## NVMe SSD Power Loss Protection (PLP)

The OcientAIQ™ Unified Data Platform uses NVMe Solid State Drives (SSD) to store data.

To improve input or output (I/O) performance, SSDs cache data in a volatile memory temporary buffer before it is flushed to non-volatile flash memory. During a normal shutdown, the host system notifies the SSD that the system is shutting down so it can flush data to non-volatile storage. However, unexpected power loss can result in loss or corruption of this data if this volatile memory is not preserved. To protect against this data loss, NVMe drives validated for use with Ocient Systems must include Power Loss Protection (PLP) mechanisms. PLP is standard in enterprise and datacenter-grade NVMe drives. They are typically implemented using super capacitors that can hold enough power to allow safe writing of cached data to non-volatile memory in the event of a power loss to ensure data integrity.

## Ocient Distributed System Protections

While data is loaded, it temporarily resides in Memory (RAM) or Disk Caches. The data stored in either of these locations is safely persisted to disks during a planned shutdown of nodes. The operating system or software might not be able to persist this

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

data to disk during an unplanned power loss or system crash, so Ocient is designed to handle this scenario gracefully.

Ocient provides redundancy mechanisms using clustering to prevent metadata loss due to a sudden power outage on a single node. The Administrator cluster consists of multiple nodes performing the Administrator role that maintain system metadata. This prevents metadata loss when a single node is lost or damaged.

Foundation storage clusters use parity configuration to protect data in the event of sudden power loss to a Foundation Node. In such an event, inflight queries might fail but without any permanent loss of data. Dynamic rebuilding of missing data allows a configurable number of Foundation Nodes to lose power and Ocient can continue to serve queries. If power loss damages a Foundation Node or causes data corruption, the data on the damaged Foundation Node can be rebuilt with the information available in parity bits on other nodes to fully recover lost data.

This might not hold true in simultaneous power loss on more than one Administrator Node or simultaneous power loss on more Foundation Nodes than the number of parity bits in the storage cluster. Such coordinated power loss could leave an Ocient System in a state where Administrator metadata is corrupted or damaged data on Foundation Nodes cannot be fully rebuilt. To prevent simultaneous power loss, the following best practices are recommended.

## Power Safety Best Practices

The risk of complete system loss can be greatly reduced by avoiding sudden loss of power to an Ocient System. Best practices to reduce this risk are:

- NVMe Drives must include PLP.
- Each Ocient node should be configured with redundant power supplies, where each power supply is serviced by independent electrical circuits.
- A rack or Data Center (DC) level Uninterruptible Power System (UPS) should be available to provide constant power to Ocient nodes during a sudden power outage.
- When power loss occurs, and the UPS system cannot provide power for an extended period of time, you must properly shut down Ocient nodes by using the **Startup and Shutdown Procedure**.

- Ocient Systems should be hosted in Tier III or Tier IV Data Centers. These Data Centers provide redundant power and cooling systems and guarantee minimal downtime.

# NVMe Drive Firmware Upgrade Process

Step-by-step process for upgrading NVMe drive firmware on Ocient Foundation Nodes to maintain drive reliability, performance, and vendor support.

The Ocient® software uses NVMe drives for storage because of their higher input or output (I/O) throughput than spinning media drives. These drives are referred to as data disks or data drives. When you run Ocient software, the Ocient System accesses these data drives using the User Mode I/O (UIO) driver during normal operation.

This procedure guides a System Administrator through binding the drives back to the NVMe driver and upgrading the drive firmware. The procedure includes steps for upgrading the firmware of only Intel® NVMe drives. For other drive models, follow a similar process using the firmware upgrade process from the manufacturer.

> ⚠ Stop the `rolehostd` process prior to working on the NVMe drives. Otherwise, when the `rolehostd` process is running, the process becomes unstable because it has open file handles on the drives.

Execution of this process requires the sudo privilege on the node where the drive firmware is updated.

## Prerequisites

Perform the firmware upgrade on one node of any specified type (Foundation, Loader, SQL) at a time. You can execute the firmware upgrade in parallel on different types of nodes.

> ⓘ Perform the upgrade during a maintenance window because issues with the upgrade might prevent the node from returning to service.

The prerequisites for this procedure are:

1. The following packages are installed on the node undergoing firmware upgrade:

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- `smartmontools`
- `nvme-cli`
- `intelmas`
- `sedutil`

2. The target firmware version for the upgrade is known and documented.
3. If you upgrade the data drive firmware on a Loader Node, prior to beginning the procedure, take the node out of the loading path by updating the LAT configuration. Before you shut down the `rolehostd` process, drain the pages that are held by the node.

The following example illustrates the firmware update commands used for an Intel NVMe SSD. Please substitute the appropriate command for your drive manufacturer in each of the steps that use the `intelmas` command.

# Firmware Upgrade Procedure

The following steps require `sudo` permissions on the node.

## Prepare for the Firmware Upgrade

1. Log in to the node as an administrator user.

2. If you upgrade the drive firmware on a Foundation Node or Loader Node, save the status of the drives for later in the procedure. After you replace `<IP_ADDRESS_OF_THE_NODE>` with the IP address of your node, save the output of this command.

CURL

```
curl -s http://<IP_ADDRESS_OF_THE_NODE>:9090/v1/stats | jq -r '.[] | select (.nam
 "localStorageService.device.status" ) | "(.device) (.value)" '
```

Alternatively, you can run a query on the SQL Node to display the status of the individual storage device and firmware version. After you replace `<NODE_NAME>` with the name of your node, connect to any SQL Node on the system and run this query.

© 2026 Ocient, Inc

SQL

```sql
SELECT
  s.id AS serial_number,
  s.pci_address,
  s.device_status,
  s.firmware_version
FROM
  sys.nodes n
JOIN sys.storage_device_status s
  ON n.id = s.node_id
WHERE
  n.name = '<NODE_NAME>';
```

Output

Text

```
serial_number     |pci_address |device_status |firmware_version
------------------+------------+--------------+----------------
CVMD6356009M800GGN|0000:3b:00.0|ACTIVE        |VDV10184
CVMD636400BZ800GGN|0000:3c:00.0|ACTIVE        |VDV10184
CVMD636400JA800GGN|0000:5e:00.0|ACTIVE        |VDV10184
CVMD6365003C800GGN|0000:5f:00.0|ACTIVE        |VDV10184
CVMD6365003P800GGN|0000:86:00.0|ACTIVE        |VDV10184
CVMD63650092800GGN|0000:87:00.0|ACTIVE        |VDV10184
PHLJ0431019J8P0HGN|0000:88:00.0|ACTIVE        |VDV10184
PHLJ106500018P0HGN|0000:89:00.0|ACTIVE        |VDV10170
```

3. If you upgrade the drive firmware on a SQL Node, save the output of the `df` command.

## Stop the `rolehostd` Process and Attach the Data Drives

1. Stop the `rolehostd` process to ensure that the drive replacement does not impact system stability.

Shell

```
sudo systemctl stop rolehostd
```

2. Prevent the `rolehostd` process from starting after reboot.

Shell

```
sudo systemctl disable rolehostd
```

3. Confirm that the output of this command indicates that the `rolehostd` process is not running and that the process auto start on reboot setting is disabled.

Shell

```
sudo systemctl status rolehostd
```

When you upgrade the drive firmware, you can impact data reliability while the `rolehostd` process is running on the node.

4. Attach the data drives to the NVMe driver.

Shell

```
sudo /opt/ocient/scripts/nvme-driver-util.sh bind-nvme
```

5. Ensure that all drives are not the operating system drive and are attached to the NVMe driver in the output of this command. Any drives that did not bind to the NVMe driver in the previous step do not upgrade, so you must investigate any failure to bind to the NVMe driver.

Shell

```
/opt/ocient/scripts/nvme-driver-util.sh
```

© 2026 Ocient, Inc

**INCORRECT**: Eight data drives are attached to the UIO driver. This is the incorrect system state for performing a firmware upgrade.

Text

```
./opt/ocient/scripts/nvme-driver-util.sh

0000:3c:00.0    0               uio_pci_generic         -
0000:5e:00.0    0               uio_pci_generic         -
0000:5f:00.0    0               uio_pci_generic         -
0000:86:00.0    1               uio_pci_generic         -
0000:87:00.0    1               uio_pci_generic         -
0000:88:00.0    1               uio_pci_generic         -
0000:89:00.0    1               uio_pci_generic         -
```

**CORRECT**: The data drives are attached to the NVMe driver. This is the correct system state for performing a firmware upgrade.

© 2026 Ocient, Inc

Text

```
./opt/ocient/scripts/nvme-driver-util.sh
NVMe device status

use option 'bind-uio' to bind uio_pci_generic driver to Ocient Payload/unpartitio
use option 'bind-nvme' to bind nvme driver to drives

BDF             Numa Node       Driver name             Device name
0000:01:00.0    0               nvme                    nvme0n1
0000:3b:00.0    0               nvme                    nvme1n1
0000:3c:00.0    0               nvme                    nvme2n1
0000:5e:00.0    0               nvme                    nvme3n1
0000:5f:00.0    0               nvme                    nvme4n1
0000:86:00.0    1               nvme                    nvme5n1
0000:87:00.0    1               nvme                    nvme6n1
0000:88:00.0    1               nvme                    nvme7n1
0000:89:00.0    1               nvme                    nvme8n1
```

## Perform Firmware Upgrade

1. Run this command and review the `FirmwareUpdateAvailable` field to identify the drives that need a firmware upgrade. Save the results of this step for comparison later in the process.

Example

```
sudo intelmas show  -d Index, SerialNumber, DeviceStatus, Capacity, FirmwareUpdat
```

Drive 8 needs the firmware update, but drive 7 does not need the update.

© 2026 Ocient, Inc

Output

```
- 7 Intel SSD DC P4510 Series PHLJ0431019J8P0HGN -

Capacity : 8001.56 GB
DeviceStatus : Healthy
FirmwareUpdateAvailable : The selected drive contains current firmware as of this
Index : 7
SerialNumber : PHLJ0431019J8P0HGN

- 8 Intel SSD DC P4510 Series PHLJ106500018P0HGN -

Capacity : 8001.56 GB
DeviceStatus : Healthy
FirmwareUpdateAvailable : Firmware=VDV10170 Bootloader=VB1B0172
Index : 8
SerialNumber : PHLJ106500018P0HGN
```

2. Execute this command for every drive in the previous step that indicates an old firmware in the `FirmwareUpdateAvailable` field. Replace `<DRIVE_INDEX>` with the number shown in the `Index` field from the output of the previous command for all drives that require the update.

Shell

```
sudo intelmas load -intelssd <DRIVE_INDEX>
```

3. Ensure that the output shows `Firmware updated successfully.` This is the sample log output for the upgrade.

Text

```
- intelmas load -intelssd 8
WARNING! You have selected to update the drives firmware!
Proceed with the update? (Y|N): Y
Checking for firmware update...

- Intel SSD DC P4510 Series PHLJ106500018P0HGN -

Status : Firmware updated successfully. Please reboot the system.
```

4. After you upgrade all drives that require the firmware upgrade, reboot the node using the `reboot` command. After the node completes the reboot, log in to the node as an administrator.

5. Attach the data drives to the NVMe driver using this command.

Shell

```
sudo /opt/ocient/scripts/nvme-driver-util.sh bind-nvme
```

6. Compare the output of this command with the output of the same command captured earlier in this process. Ensure that the reported drive status and capacity are the same as before the upgrade and that the firmware shown is current.

Shell

```
sudo intelmas show -d Index, SerialNumber, DeviceStatus, Capacity, FirmwareUpdate
```

7. Reattach the data drives to the UIO driver.

Shell

```
sudo /opt/ocient/scripts/nvme-driver-util.sh bind-uio
```

## Enable the `rolehostd` Process and Perform Final Checks

1. Enable the `rolehostd` process to start after reboot, and then start the process.

Shell

```
sudo systemctl enable rolehostd && sudo systemctl start rolehostd
```

2. Ensure that the `rolehostd` process is enabled and started.

Shell

```
sudo systemctl status rolehostd
```

3. If you upgrade the firmware of the drive on a Foundation Node or Loader Node, ensure that the output of this command matches the output of the same command captured earlier in this process.

CURL

```
curl -s http://<IP_ADDRESS_OF_THE_NODE>:9090/v1/stats | jq -r '.[] | select (.nam
```

Alternatively, you can run a query on the SQL Node to capture the individual device status and firmware version. Ensure that the drives and statuses in this query match the results from the query you executed earlier in this process. After you replace the node name `<NODE_NAME>` with the name of your node, connect to any SQL Node on the system and execute this query.

SQL

```
SELECT
  s.id as serial_number,
  s.pci_address,
  s.device_status,
  s.firmware_version
FROM
  sys.nodes n
JOIN sys.storage_device_status s
  ON n.id = s.node_id
WHERE
  n.name = '<NODE_NAME>';
```

Output

Text

```
serial_number     |pci_address |device_status |firmware_version
------------------+------------+--------------+----------------
CVMD6356009M800GGN|0000:3b:00.0|ACTIVE        |VDV10184
CVMD636400BZ800GGN|0000:3c:00.0|ACTIVE        |VDV10184
CVMD636400JA800GGN|0000:5e:00.0|ACTIVE        |VDV10184
CVMD6365003C800GGN|0000:5f:00.0|ACTIVE        |VDV10184
CVMD6365003P800GGN|0000:86:00.0|ACTIVE        |VDV10184
CVMD63650092800GGN|0000:87:00.0|ACTIVE        |VDV10184
PHLJ0431019J8P0HGN|0000:88:00.0|ACTIVE        |VDV10184
PHLJ106500018P0HGN|0000:89:00.0|ACTIVE        |VDV10184
```

4. If you upgrade the firmware of the drive on a SQL Node, ensure that the output of the `df` command shows the same mount points as those captured earlier in this process.

# Replace an NVMe Node Drive

Procedure for replacing an NVMe drive on an Ocient Foundation Node, including service rotation, drive bootstrapping, and segment rebuild to restore redundancy.

Ocient® software uses NVMe drives for storage because of their higher input or output (I/O) throughput than spinning media drives. These drives are referred to as data disks or drives.

In Ocient, these drives are accessed through a User Mode I/O (UIO) driver, so they cannot be accessed using the common set of Linux® commands (e.g., df/du/ls/file/parted/etc).

> ⚠ Working on these drives requires the `rolehostd` process to be stopped on the node, because the process has open file handles on the drives and making changes to the drive can make the process unstable.

Execution of this process requires `sudo` privilege on the Foundation Node on which the drive is being replaced.

## Detection and Alerting

There are two approaches for detecting issues with NVMe drives on a Foundation Node. The device status of all drives on a specific Foundation Node can be checked using a SQL query of the system catalog to ensure all are active. Secondly, the presence of NVMe drives on the PCI bus can be inspected. You can run each command on a Foundation Node to assess the health of the drives on that node. Depending on the failure mode of a device, either of these methods could reveal an issue with an NVMe drive.

> ⓘ In the case of an operating system drive failure, contact Ocient Support.

### Check Drive Status Using System Catalog Tables

SQL queries on the `sys.storage_device_status` system catalog table provide a status of all payload drives. Connect to any SQL Node on the system and execute this query, replacing `<NODE_NAME>` with the name of your node.

© 2026 Ocient, Inc

SQL

```sql
SELECT
  n.name AS node_name,
  s.node_id,
  s.id AS serial_number,
  s.pci_address,
  s.device_status,
  s.device_model
FROM
  sys.nodes n
JOIN sys.storage_device_status s
  ON n.id = s.node_id
WHERE
  n.name = '<NODE_NAME>';
```

*Output*

Text

```
node_name |node_id                               |serial_number     |pci_address |dev

```

The possible storage device statuses are `ACTIVE` or `FAILED`. In this sample output, the device in PCI Address `0000:89:00.0` needs to be replaced.

If an NVMe drive is completely unavailable, it might not appear in the `sys.storage_device_status` table. For example, if a drive is not seated properly or if the node has rebooted and the drive is undetectable by Ocient. In this case, see the **Alternative Methods to Identify Failed Drives** to identify the serial number and PCI address of the drive.

In the event that a drive has failed or is experiencing issues, errors are logged in `/var/log/messages` and `/var/opt/ocient/log/rolehostd.log*` files. Inspection of these log files can assist with root cause analysis of the drive failure.

# Troubleshooting

1. To locate the failed drive in the chassis, use the query results from the **Check Drive Status Using System Catalog Tables** query to identify the PCI Address of the failed drive.
2. Refer to the chassis diagram for your system to identify the slot of the failed drive based on the PCI address. Three common chassis and drive bay mappings are listed below:

Supermicro® **SYS-1029U-TN10RT Hot swap bays**

| NVMe 3c:00.0 | NVMe 5f:00.0 | NVMe 61:00.0 | NVMe 87:00.0 | NVMe 89:00.0 |
|---|---|---|---|---|
| NVMe 3b:00.0 | NVMe 5e:00.0 | NVMe 60:00.0 | NVMe 86:00.0 | NVMe 88:00.0 |

# Recovery

## Prerequisites

- An NVMe drive of the same model and the same or larger capacity as the failed drive.
- The drive firmware is upgraded to the latest version using the **NVMe Drive Firmware Upgrade Process**.

## Replacement Procedure

1. Log in to the Foundation Node that needs a drive replacement as an administrator user and stop the `rolehostd` process on this node to ensure that the drive replacement does not impact the stability of the process:

```shell
sudo systemctl stop rolehostd
```

2. Ensure that the `rolehostd` process has stopped. The result of this command should indicate that the process is `Stopped`.

Shell

```
sudo systemctl status rolehostd
```

3. If using encrypted OPAL drives, back up the localKeyStore directory. This directory can be empty or absent on systems that do not have OPAL drives.

Shell

```
sudo cp -pR /var/opt/ocient/localKeyStore /root
```

4. Physically remove the failed drive from the host and execute `nvme-driver-util.sh` to ensure that the failed drive is not showing up in the output.

Shell

```
/opt/ocient/scripts/nvme-driver-util.sh
```

*Output*

Text

```
[admin@go-lts9 ~]$ /opt/ocient/scripts/nvme-driver-util.sh
NVMe device status

use option 'bind-uio' to bind uio_pci_generic driver to Ocient Payload/unpartitione
use option 'bind-nvme' to bind nvme driver to drives

BDF             Numa Node       Driver name             Device name
0000:3b:00.0    0               uio_pci_generic         -
0000:3c:00.0    0               uio_pci_generic         -
0000:5e:00.0    0               uio_pci_generic         -
0000:5f:00.0    0               uio_pci_generic         -
0000:86:00.0    1               uio_pci_generic         -
0000:87:00.0    1               uio_pci_generic         -
0000:88:00.0    1               uio_pci_generic         -
[admin@go-lts9 ~]$
```

5. Insert the replacement drive in the chassis and ensure that it shows up in the output of the `nvme-driver-util.sh` script.

Shell

```
/opt/ocient/scripts/nvme-driver-util.sh
```

*Output*

Text

```
[admin@go-lts9 ~]$ /opt/ocient/scripts/nvme-driver-util.sh
NVMe device status

use option 'bind-uio' to bind uio_pci_generic driver to Ocient Payload/unpartitione
use option 'bind-nvme' to bind nvme driver to drives

BDF             Numa Node       Driver name             Device name
0000:3b:00.0    0               uio_pci_generic         -
0000:3c:00.0    0               uio_pci_generic         -
0000:5e:00.0    0               uio_pci_generic         -
0000:5f:00.0    0               uio_pci_generic         -
0000:86:00.0    1               uio_pci_generic         -
0000:87:00.0    1               uio_pci_generic         -
0000:88:00.0    1               uio_pci_generic         -
0000:89:00.0    1               nvme                    -
[admin@go-lts9 ~]$
```

6. Run this command by replacing `X` and `Y` to match the device name using the replacement drive.

Text

```
sudo nvme format /dev/nvmeXnY format --ses=1
```

⚠ This command formats the specified drive and erases all data on the drive. If the OS drive is an NVMe drive, ensure that it is not formatted.

7. Execute the `nvme-driver-util.sh` script to bind drives to the UIO driver:

Shell

```
sudo /opt/ocient/scripts/nvme-driver-util.sh bind-uio
```

8. Execute `nvme-driver-util.sh` script and confirm that the new drive is bound to `uio_pci_generic` driver.

Shell

```
/opt/ocient/scripts/nvme-driver-util.sh
```

*Output*

Text

```
[admin@go-lts9 ~]$ /opt/ocient/scripts/nvme-driver-util.sh
NVMe device status

use option 'bind-uio' to bind uio_pci_generic driver to Ocient Payload/unpartitione
use option 'bind-nvme' to bind nvme driver to drives

0000:86:00.0    1               uio_pci_generic         -
0000:87:00.0    1               uio_pci_generic         -
0000:88:00.0    1               uio_pci_generic         -
0000:89:00.0    1               uio_pci_generic         -
[admin@go-lts9 ~]$
```

9. Start the `rolehostd` process.

Shell

```
sudo systemctl start rolehostd
```

10. Check the output of the `sys.storage_device_status` catalog table by connecting to a SQL Node and running by following query after replacing the `<NODE_NAME>` with the name of your node. Ensure that all drives appear on the node with status of `ACTIVE`.

SQL

```sql
SELECT
  n.name AS node_name,
  s.node_id,
  s.id AS serial_number,
  s.pci_address,
  s.device_status,
  s.model
FROM
  sys.nodes n
JOIN sys.storage_device_status s
  ON n.id = s.node_id
WHERE
  n.name = '<NODE_NAME>';
```

*Output*

Text

```
node_name |node_id                                |serial_number     |pci_address |dev
----------+---------------------------------------+------------------+------------+---
lts2      |f4845f46-dd0a-48bd-a2ed-614d5029e5df|CVMD6356009M800GGN|0000:3b:00.0|ACT
lts2      |f4845f46-dd0a-48bd-a2ed-614d5029e5df|CVMD636400BZ800GGN|0000:3c:00.0|ACT
lts2      |f4845f46-dd0a-48bd-a2ed-614d5029e5df|CVMD636400JA800GGN|0000:5e:00.0|ACT
lts2      |f4845f46-dd0a-48bd-a2ed-614d5029e5df|CVMD6365003C800GGN|0000:5f:00.0|ACT
lts2      |f4845f46-dd0a-48bd-a2ed-614d5029e5df|CVMD6365003P800GGN|0000:86:00.0|ACT
lts2      |f4845f46-dd0a-48bd-a2ed-614d5029e5df|CVMD636500928OOGGN|0000:87:00.0|ACT
lts2      |f4845f46-dd0a-48bd-a2ed-614d5029e5df|CVMD6365009H800GGN|0000:88:00.0|ACT
lts2      |f4845f46-dd0a-48bd-a2ed-614d5029e5df|CVMD637100GA800GGN|0000:89:00.0|ACT
```

As shown in the sample output, the device replaced at PCI Address `0000:89:00.0` is now active. This indicates that it has been successfully replaced.

## Next Steps: Rebuild Segments

If the failed drive had data on it prior to failure, a rebuild of data segments stored on the replaced drive is required after the drive is replaced. Refer to the **Guide to Rebuilding Segments** for instructions on how to rebuild the missing segments.

© 2026 Ocient, Inc

# Alternative Methods to Identify Failed Drives

If the results of querying the `sys.storage_device_status` table do not indicate which drive has failed, alternative methods can be used to detect the failing drive. These methods require the command-line utility `jq`, but you can view the full results of the `curl` commands without it.

## Option 1: Cross Reference API Results to Identify the PCI Address

You can cross-reference the result of two API commands to determine the PCI address of the failed drive that is not appearing. A drive that does not appear in the `stats` API or catalog table can be present in the `sysconfig` API output.

The output of the following API shows NVMe storage device statuses. Any device status other than 10 indicates a potential issue. Replace `<IP_ADDRESS_OF_THE_NODE>` with the IP Address of your node and inspect the results.

CURL

```
curl -s http://<IP_ADDRESS_OF_THE_NODE>:9090/v1/stats | jq -r '.[] |select (.name =
```

*Output*

Text

```
$ curl -s http://1.2.3.4:9090/v1/stats | jq -r '.[] |select (.name == "localStorage
BTLJ913605YR2P0BGN 10
BTLJ913608AY2P0BGN 10
BTLJ913608FR2P0BGN 10
BTLJ91360D6Q2P0BGN 10
BTLJ91360D6Y2P0BGN 10
BTLJ916306LS2P0BGN 10
BTLJ92020KP22P0BGN 10
BTLJ92030AJM2P0BGN 10
PHLJ9403002N2P0BGN 10
PHLJ941100RW2P0BGN 10
```

The possible device status values are listed in the table below:

© 2026 Ocient, Inc

| Value | Device Status |
|---|---|
| 0 | INVALID_UNKNOWN |
| 10 | ACTIVE |
| 20 | UNINITIALIZED |
| 61 | CORRUPT |
| 80 | FAILED |

## Check Device Presence

The output of the following API will show the configured NVMe drives on the Foundation Node. Depending on the failure mode, the output of this command can show a reduced number of drives. For example, if the Foundation Node chassis has 12 drive bays populated and only 11 appear in this result, it would indicate that one drive is not visible to Ocient. Run the following command by replacing `<IP_ADDRESS_OF_THE_NODE>` with the IP Address of your node:

CURL

```
curl -s http://<IP_ADDRESS_OF_THE_NODE>:9090/v1/sysconfig | jq -r '.storage_devices
```

*Output*

Text

```
$ curl -s http://1.2.3.4:9090/v1/sysconfig | jq -r '.storage_devices[] | select ( .

If the address of the failed drive cannot be determined in this way, proceed to Option 2 to identify the location of the drive.

### Option 2: Inspect Drives Using Operating System Commands

If drives are not appearing in the Ocient outputs, they might be unavailable to the Ocient service. In this case, directly examine the drives on the system with standard disk utilities and operating system commands to find the serial numbers of drives that meet the following criteria:

1. The drive is not the operating system boot drive.
2. The drive is not listed in the `sys.storage_device_status` table.

Any drives that meet this criteria are not in use by Ocient and might need to be replaced or repaired. Identify the Serial Number and PCI Addresses of these drives in order to complete the replacement procedure.

# Expand and Rebalance System

Expand an Ocient System by adding storage and SQL nodes, then rebalance segments across the cluster to maintain capacity, performance, and fault tolerance.

If your system needs more resources, you can expand it by installing additional nodes and drives. The steps for expanding a system depend on the type of node you are adding.

These sections explain the steps for adding each Ocient® node type. Foundation Nodes include additional steps for adding more storage drives and rebalancing the system.

> For information on how to replace nodes that have failed or are damaged, see **Replace Nodes**.
>
> For information on replacing drives that have failed or are damaged, see **Replace an NVMe Node Drive**.

## Prerequisites

These prerequisites apply to adding any node type:

- The process requires either the System Administrator role or the granted UPDATE privilege on SYSTEM.
- Any new nodes should have the same OS kernel version as other nodes in the system.
- Any new nodes should have the same Ocient System version as the other nodes. For details, see **Ocient Application Installation**.
- Ensure that your system meets the requirements outlined in **Ocient System Bootstrapping**.
- Before adding nodes, stop any query or loading process running on your system.

## Add Foundation Nodes

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

A core component of an Ocient System, the Foundation Nodes store user data in Ocient and perform the bulk of query processing. By adding more Foundation Nodes, a system can support extra storage capacity as well as better performance for query processing.

This process requires rebalancing the data to distribute the query processing across all available hardware, including newly installed disks or nodes.

## System Considerations

- No individual cluster should have more than two petabytes of storage.
- Each cluster should have the same number of Foundation Nodes.

## Tutorial

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

1. Create the `/var/opt/ocient/bootstrap.conf` file on the new node using this YAML example. This YAML file should follow a similar format and parameters as the `bootstrap.conf` files on your other nodes.

   Replace the `<FIRST_NODE_ADDRESS>` with the IP or Hostname of a node running the Administrator Role on your system. If you are not using DNS, use `nodeAddress` instead of `adminHost`.

   Generate a `nodeToken` value by executing the `GET NODE TOKEN` SQL statement using a database connection to an existing node. Each token is single-use and expires after 15 minutes by default, so generate it shortly before starting the node.

   YAML

   ```yaml
   adminHost: <FIRST_NODE_ADDRESS>
   nodeToken: <token_from_GET_NODE_TOKEN>
   ```

   > You can also use `adminUserName` and `adminPassword` instead of `nodeToken`, but this approach is deprecated. Use node tokens for improved security. If the password for the system administrator has changed, set the correct username and password in `bootstrap.conf`.

2. Start the new node by using this command.

   Shell

   ```
   sudo systemctl start rolehostd
   ```

   This process takes about a minute to complete. This step accepts the node into the system, but it has not been assigned a role or a storage cluster.

3. To validate that the node is on the system, execute this query using the `sys.nodes` system catalog table.

```sql
SELECT name, status
FROM sys.nodes
ORDER BY 1;
```

*Output*

```sql
name                                status
------------------------------------------------------------------------
admin01                             ACCEPTED
admin02                             ACCEPTED
admin03                             ACCEPTED
loader01                            ACCEPTED
loader02                            ACCEPTED
loader03                            ACCEPTED
foundation01                        ACCEPTED
foundation02                        ACCEPTED
foundation03                        ACCEPTED
foundation04                        ACCEPTED
foundation05                        ACCEPTED
foundation06                        ACCEPTED
foundation07                        ACCEPTED
foundation08                        ACCEPTED
foundation09                        ACCEPTED
foundation10                        ACCEPTED
foundation11                        ACCEPTED
foundation12                        ACCEPTED
foundation_new                      ACCEPTED
sql01                               ACCEPTED
sql02                               ACCEPTED
```

The output shows the new node, named `foundation_new` in this example, listed as `ACCEPTED` in the `status` column.

4 Execute this `ALTER CLUSTER` SQL statement to add the new node to a storage cluster. In this example, replace `storage_cluster_1` and `foundation_new` with

your cluster name and node name, respectively.

```
SQL
ALTER CLUSTER "storage_cluster_1"
    ADD PARTICIPANTS "foundation_new";
```

> This example adds only one new node. For information on adding multiple nodes, see **ALTER CLUSTER ADD PARTICIPANTS**.

5 Restart the `rolehostd` process on all nodes in the system by running the following series of commands at the shell terminal.

First, stop the `rolehostd` process on all nodes.

```
Shell
sudo systemctl kill -s SIGKILL rolehostd
```

Confirm that the `rolehostd` process is no longer running.

```
Shell
sudo systemctl status rolehostd
```

Start the `rolehostd` process on the system again.

```
Shell
sudo systemctl start rolehostd
```

6 You can verify the new node is active by executing this SQL query after you connect to the database.

SQL

```
SELECT n.name,
       ns.operational_status
FROM sys.node_status ns
JOIN sys.nodes n ON ns.node_id = n.id
ORDER BY n.name;

name                                operational_status
---------------------------------------------------------------------------
admin01                             Active
admin02                             Active
admin03                             Active
loader01                            Active
loader02                            Active
loader03                            Active
foundation01                        Active
foundation02                        Active
foundation03                        Active
foundation04                        Active
foundation05                        Active
foundation06                        Active
foundation07                        Active
foundation08                        Active
foundation09                        Active
foundation10                        Active
foundation11                        Active
foundation12                        Active
foundation_new                      Active
sql01                               Active
sql02                               Active
```

7 Perform a rebalance task to distribute your data across your newly expanded system evenly. For details, see **Rebalance System**.

## Add More Drives to Foundation Nodes

Foundation Nodes can support extra storage by adding additional NVMe drives. This tutorial shows the steps to integrate new drives into an existing Ocient System.

## System Considerations

- For best performance, all Foundation Nodes should have equal storage capacity.
- No individual cluster should have more than two petabytes of storage.

## Prerequisites

- The process requires `systemctl` access on your system OS.
- Any new NVMe drives added to the system must be blank and unpartitioned.

## Tutorial

1. Shut down the `rolehostd` process from the shell prompt.

   Shell

   ```
   sudo systemctl stop rolehostd
   ```

2. Install the new storage drives in your system.

3. Restart the node from the shell prompt.

   Shell

   ```
   sudo systemctl restart rolehostd
   ```

   The `rolehostd` process recognizes the new drive.

4. To confirm the new drives are active and running, you can connect to your system and query the **sys.storage_device_status** system catalog table.

To use this example query, replace `<NODE_NAME>` with the name of the node where you are adding a drive.

SQL

```
SELECT
  n.name AS node_name,
  s.node_id,
  s.id AS serial_number,
  s.pci_address,
  s.device_status,
  s.device_model
FROM
  sys.nodes n
JOIN sys.storage_device_status s
  ON n.id = s.node_id
WHERE
  n.name = '<NODE_NAME>';
```

*Output*

Text

```
|node_name  |node_id                               |serial_number
|-----------|--------------------------------------|------------------------
|foundation0|9330a0b3-b3b7-4503-949c-043b196c0cc4|6156962f-fcf6-4299-bbd7-2
|foundation0|9330a0b3-b3b7-4503-949c-043b196c0cc4|e6a4b24f-0d49-4704-b7ce-1
```

This output lists the serial numbers of all drives in the `foundation0` node, including their statuses.

5 Perform a rebalance task to distribute your data across your newly expanded system evenly. For details, see **Rebalance System**.

# Rebalance System

`REBALANCE` task execution redistributes your data evenly across your segment groups and clusters. Rebalance your system if you have recently installed new hardware, particularly new nodes or drives.

## System Considerations

Currently, the `REBALANCE` task does not move damaged segment groups. If you suspect that you might have a significant number of damaged segment groups, you can execute these steps to check and fix the groups:

1. Ensure all nodes are online.
2. Check whether you have damaged segment groups using the `sys.segment_groups` system catalog table. If damaged segment groups are present, execute a `REBUILD` task to rebuild the groups before rebalancing the system. For details, see **Guide to Rebuilding Segments**.
3. Execute the `REBALANCE` task using this tutorial.

You can find information in the `sys.degraded_segment_groups` system catalog table to identify the damaged segment groups that need fixing. This table shows all segment groups with the `DAMAGED` or `UNAVAILABLE` state. You can also check the `sys.storage_used` system catalog table, which shows approximately the same number of used bytes `used_bytes` for each node entry with the same table after the rebalance execution.

## Prerequisites

- Only one rebalance task can execute at a time on the system. The system logs an error if you try to start a second rebalance task.
- You must have the System Administrator role, or be granted the UPDATE privilege on SYSTEM.

## Tutorial

**1** Execute a `SELECT` SQL statement to view how the system has distributed the existing data using the `sys.tables` and `sys.nodes` system catalog tables.

SQL

```
SELECT t.name AS table_name,
    n.name AS node_name,
    su.used_bytes FROM sys.storage_used su
    JOIN sys.tables t ON t.id = su.table_id
    JOIN sys.nodes n ON n.id = su.node_id
ORDER BY t.name,
    n.name;
```

*Output*

Text

```
+-------------------------+-----------+--------------+
| table_name              | node_name |   used_bytes |
|-------------------------+-----------+--------------|
| table0                  | lts0      |     48000000 |
| table0                  | lts1      |     11000000 |
| table0                  | lts2      |     79000000 |
| table0                  | lts3      |     73000000 |
| table0                  | lts4      |     85000000 |
| table0                  | lts5      |     50000000 |
| table0                  | lts6      |     51000000 |
| table0                  | lts7      |     41000000 |
| table1                  | lts0      |     66000000 |
| table1                  | lts1      |     77000000 |
| table1                  | lts2      |     73000000 |
| table1                  | lts3      |     43000000 |
| table1                  | lts4      |     76000000 |
| table1                  | lts5      |     51000000 |
| table1                  | lts6      |     71000000 |
| table1                  | lts7      |    105000000 |
```

The query output shows how data is distributed across your nodes.

2 Execute the `REBALANCE` task named `rebalance_task` to reorganize all data in a balanced state using the `CREATE TASK` SQL statement.

SQL

```
CREATE TASK rebalance_task TYPE REBALANCE;
```

For details about the syntax for creating tasks, see **Distributed Tasks**.

3 View the status of the tasks as the rebalance operation executes using the `sys.subtasks` system catalog table.

SQL

```
SELECT id,
    name,
    start_time,
    task_type,
    execution_type,
    status,
    details
FROM sys.subtasks
WHERE task_type = 'rebalance'
ORDER BY start_time DESC;
```

*Output*

Text

```
+--------------------------------------+--------+--------------------------
| id                                   | name   | start_time
|--------------------------------------+--------+--------------------------
| ed68a070-d7f7-4c50-9b94-84b04b4503c2 |        | 2024-04-17 21:44:20.26800
| 9e6c3374-6e9c-4a84-9bf8-ba1db3d866eb |        | 2024-04-17 21:44:20.26800
| aebb75d8-e066-4813-b7e8-c272e5a3b8e9 |        | 2024-04-17 21:44:14.76800
| 5cec5095-8b3a-4868-a10d-35fe6a32e998 |        | 2024-04-17 21:44:14.56400
+--------------------------------------+--------+--------------------------
```

The output shows when the `REBALANCE` task is finished.

When the `REBALANCE` task runs, segments are in the `REBUILDING` state. After the Ocient System completes this task, all segments should transition to the `INTACT` state.

4 Execute the query from Step 1 again to see how the system reorganized the data across nodes.

SQL

```
SELECT t.name,
    n.name,
    su.used_bytes
FROM sys.storage_used su
    JOIN sys.tables t ON t.id = su.table_id
    JOIN sys.nodes n ON n.id = su.node_id
ORDER BY t.name,
    n.name;
```

*Output*

Text

```
+------------------------+----------+--------------+
| name                   | name_1   |   used_bytes |
|------------------------+----------+--------------|
| table0                 | lts0     |     48000000 |
| table0                 | lts1     |     39000000 |
| table0                 | lts2     |     71000000 |
| table0                 | lts3     |     53000000 |
| table0                 | lts4     |     85000000 |
| table0                 | lts5     |     50000000 |
| table0                 | lts6     |     51000000 |
| table0                 | lts7     |     41000000 |
| table1                 | lts0     |     66000000 |
| table1                 | lts1     |     77000000 |
| table1                 | lts2     |     73000000 |
| table1                 | lts3     |     43000000 |
| table1                 | lts4     |     76000000 |
| table1                 | lts5     |     68000000 |
| table1                 | lts6     |     71000000 |
| table1                 | lts7     |     88000000 |
```

The output shows the redistributed data.

> The `REBALANCE` task redistributes data across segment groups, so there can be some variance in data across nodes.

# Add Loader Nodes

Adding more Loader Nodes to your system can improve the throughput of data loading and resiliency against loading failure. By having extra Loader Nodes, you can also dedicate sets of nodes for specific pipelines.

## System Considerations

Before starting this process, ensure you meet the requirements in the **Prerequisites** section.

## Tutorial

1. Stop any active data pipelines. Execute this SQL statement by replacing `pipeline_name` with the name of your data pipeline.

```sql
STOP PIPELINE <pipeline_name>;
```

2. Create the `/var/opt/ocient/bootstrap.conf` file on the new Loader Node using this YAML example. This YAML file should follow a similar format and parameters to the `bootstrap.conf` file on your other nodes.

   Replace the `<FIRST_NODE_ADDRESS>` with the IP address or hostname of a node running the Administrator Role on your system. If you are not using a DNS, use `nodeAddress` instead of `adminHost`.

   Generate a `nodeToken` value by executing the `GET NODE TOKEN` SQL statement using a database connection to an existing node. Each token is single-use and expires after 15 minutes by default, so generate it shortly before starting the node.

```yaml
adminHost: <FIRST_NODE_ADDRESS>
nodeToken: <token_from_GET_NODE_TOKEN>
```

   > You can also use `adminUserName` and `adminPassword` instead of `nodeToken`, but this approach is deprecated. Use node tokens for improved security. If the password for the system administrator has changed, set the correct username and password in `bootstrap.conf`.

3. Start the new node by using this command.

Shell

```
sudo systemctl start rolehostd
```

This process takes about a minute to complete. This step accepts the node into the system, but does not assign a role.

4. Add the `streamloader` role to the new node.

   Execute this SQL statement by replacing `<new_node_name>` with the new node name.

   SQL

   ```
   ALTER NODE <new_node_name> ADD ROLE streamloader;
   ```

5. Restart the `rolehostd` process on the replacement node by running this command at the shell terminal on the replacement node.

   Shell

   ```
   sudo systemctl restart rolehostd
   ```

6. Restart the pipeline. Execute this SQL statement by replacing `pipeline_name` with the name of your data pipeline. Optionally, specify the Loader Node by name with the `USING LOADERS` keywords to prioritize it for this pipeline.

   Shell

   ```
   START PIPELINE <pipeline_name> USING LOADERS <new_node_name>;
   ```

© 2026 Ocient, Inc

If you use the legacy LAT service, you must stop loading and copy the LAT configuration files to any new Loader Nodes. For details, see **Configure the LAT Service**.

This step is unnecessary for systems that use Ocient data pipelines for loading.

# Add SQL Nodes

Adding more SQL Nodes to your system can improve query optimization and processing, particularly for aggregation and join operations. Extra SQL Nodes also provide system resiliency, especially when assigned the `admin` role.

## System Considerations

Before starting this process, ensure you meet the requirements in the **Prerequisites** section.

## Tutorial

1. Create the `/var/opt/ocient/bootstrap.conf` file on the new SQL Node using this YAML example. This YAML file should follow a similar format and parameters to the `bootstrap.conf` file on your other nodes.

   Replace the `<FIRST_NODE_ADDRESS>` with the IP address or hostname of a node running the Administrator Role on your system. If you are not using a DNS, use `nodeAddress` instead of `adminHost`.

   Generate a `nodeToken` value by executing the `GET NODE TOKEN` SQL statement using a database connection to an existing node. Each token is single-use and expires after 15 minutes by default, so generate it shortly before starting the node.

   YAML

   ```yaml
   adminHost: <FIRST_NODE_ADDRESS>
   nodeToken: <token_from_GET_NODE_TOKEN>
   ```

You can also use `adminUserName` and `adminPassword` instead of `nodeToken`, but this approach is deprecated. Use node tokens for improved security. If the password for the system administrator has changed, set the correct username and password in `bootstrap.conf`.

2 Start the new node by using this command.

Shell

```
sudo systemctl start rolehostd
```

This process takes about a minute to complete. This step accepts the node into the system, but does not assign a role.

3 Add the `sql` role to the new node.

Execute this SQL statement by replacing `<new_node_name>` with the new node name.

SQL

```
ALTER NODE <new_node_name> ADD ROLE sql;
```

4 Optionally, you can also assign the `admin` role to the SQL Node. At least one SQL Node must always fulfill this role. By default, the system assigns the `admin` role to the first SQL Node in the system.

For details about the `admin` role, see **Node Configuration with the Administrator Role**.

Execute this SQL statement by replacing `<new_node_name>` with the name of your new node.

SQL

```
ALTER NODE <new_node_name> ADD ROLE admin;
```

5 Restart the `rolehostd` process on the replacement node by running this command at the shell terminal on the replacement node.

Shell

```
sudo systemctl restart rolehostd
```

6 Assign the new SQL Node to a connectivity pool with the **ALTER CONNECTIVITY_POOL** statement.

In this example, the statement assigns the SQL Node `sql2` to the connectivity pool `cp1` with the IP address `111.1.1.1` and port number `4050` for listening. Specify the local IP address and port number `4050` to return to the client.

```sql
ALTER CONNECTIVITY_POOL cp1
    ADD PARTICIPANTS(
        NODE sql2
        LISTEN_ADDRESS '111.1.1.1'
        LISTEN_PORT 4050
        ADVERTISED_ADDRESS 'localhost'
        ADVERTISED_PORT 4050);
```

# Replace Nodes

Procedure for replacing nodes in an Ocient System, including drain, configuration, bootstrap, and segment redistribution steps to minimize downtime.

An Ocient® System requires a full node replacement in some scenarios. For example, the OS drive on a node might fail and necessitate a reinstallation and addition of the node. Other events, such as a complete node loss due to a hardware failure of the motherboard or damage to NVMe storage drives, can also cause you to replace a node.

An administrator should be familiar with the different types of nodes described in the **Core Elements of an Ocient System**. There are many similarities between the procedures for different node types, and the differences are clearly noted in the replacement procedures.

This procedure begins with **Prerequisites** then guides a System Administrator through replacing any of the Ocient node types.

This procedure also includes instructions about the replacement of an OS drive (also called a boot drive) on an Ocient node because the procedure for the replacement is identical to the replacement of the entire node. Both require reinstallation of the operating system and restoration of the configuration backup files to reestablish the identity of the Ocient System.

> ⚠ You must work carefully with nodes that also perform the Administrator Role, because you must maintain Administrator consensus.

Execution of this process requires System Administrator access to the Ocient System Database and `sudo` privilege on the node being replaced.

## Detection and Alerting

You must monitor all nodes such that the loss of a node on the system triggers a node availability alert in the monitoring system.

This table shows the potential consequences of the loss of each type of node.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### SQL Node loss

| Node Type | Impact of Node Loss |
|---|---|
| SQL | Might impact query performance in an Ocient System. |
| | If the only remaining SQL Node is lost in a system, you cannot query that system. |
| | If the SQL Node performs the Administrator Role, then the resiliency of the system could reduce to hardware failure. You must maintain the number of nodes that perform the Administrator Role at all times to maintain the resiliency of the system. |

### Foundation Node Loss

| Node Type | Impact of Node Loss |
|---|---|
| Foundation | Can impact query performance or the load of new data. |
| | The parity configuration of the storage space in the Ocient System determines if new data can be stored while a Foundation Node is disabled. |

### Loader Node Loss

| Node Type | Impact of Node Loss |
|---|---|
| Loader | Can impact the throughput of the data load in an Ocient System. |
| | If the remaining Loader Nodes are insufficient to handle the incoming data, the data can lead to a backlog. |
| | If the only remaining Loader Node is lost in a system, data loading stops. |

# Troubleshooting

You must replace a node in the event of a hardware failure of certain components. You can replace an OS drive, data drives, and RAM on most nodes. A node replacement might be necessary in the case of a CPU, motherboard, or Network Interface Card (NIC) replacement. The troubleshooting steps to recover an existing node are specific to the hardware model of the node.

© 2026 Ocient, Inc

Please contact Ocient Support for troubleshooting issues with a node.

# Recovery

## Prerequisites

- The SQL Nodes on the Ocient System are active and running Ocient (except for any SQL Nodes that are being replaced as part of this procedure).
- The OS has been installed and configured on the replacement node or OS drive for the node to be replaced.
- The replacement node has been installed with the same version of the Ocient Software as the rest of the Ocient System according to the **Ocient Application Installation**.
- The `bootstrap.conf` file for the node has been created in the `/var/opt/ocient` directory on the replacement node. For details, see **Ocient System Bootstrapping**.
- For Loader Nodes only:
  - The replacement node has been installed with the same version of the Loading and Transformation software as the rest of the Loader Nodes as described in **LAT Packaging and Installation**.
  - The following files are available from the node before the failure. If these files are not available, please contact Ocient Support for assistance.
    - `/etc/lat/lat.conf`
    - `/etc/lat/log4j2.xml`
    - `/opt/lat/.lat-data/*`

## Replacement Procedure Overview

The replacement procedure is similar for all node types, but there are differences due to the way that different node types coordinate with one another.

The general procedure is:

1. Remove the failed node from the Ocient System.
2. Register the new node with the system and Accept Node.

3. Assign roles and add to clusters where appropriate.
4. Start the new node.

If you want to reuse the name of a node, then you must rename the failed node and set the IP address. To perform these actions, use these statements.

Rename the node from `nodename` to `newnodename`.

SQL

```
ALTER NODE "nodename" RENAME TO "newnodename";
```

Set the IP address for the new node.

SQL

```
ALTER NODE "newnodename" SET ADDRESS 'newnodename';
```

# SQL Node Replacement Procedure

## Step 1: Check SQL Node for the Administrator Role.

Before you replace a SQL Node, check whether the node performs the Administrator Role in addition to the SQL Node. If the node performs the Administrator Role, then follow this additional step to add this role to the new node.

> ⚠ Most SQL Nodes are configured to also perform the Administrator Role. When you remove nodes that perform the Administrator Role, you must replace that node with another node that performs the Administrator Role so that you maintain the level of redundancy in the RAFT protocol of the administrator.

Check the results by using this query.

© 2026 Ocient, Inc

SQL

```
SELECT
    n.name AS node_name,
    sr.service_role_type
FROM sys.nodes n
LEFT JOIN sys.service_roles sr ON sr.node_id = n.id
WHERE sr.service_role_type = 'admin';
```

Text

```
node_name service_role_type
--------------------------------------------------------------------------------
----
sql0 admin
sql1 admin
sql2 admin
```

## Step 2: Remove the Failed SQL Node from the Ocient System.

Remove the node role using the `ALTER NODE` SQL statement by replacing `sql0` with the node name of your node.

SQL

```
ALTER NODE "sql0" REMOVE ROLE sql;
```

Delete the node using the `DROP NODE` SQL statement by replacing `sql0` with the node name of your node.

SQL

```
DROP NODE "sql0";
```

If the failed node still exists in the Ocient System, the system does not add the replacement node.

## Step 3: Register the New Node with the Ocient System.

Follow the **Bootstrapping Node Procedure** to register the new node. This procedure uses the `rolehostd` process to start any new nodes.

When bootstrapping the replacement node, you can reuse the original node name or assign a new one. The node name of the newly registered node is used in subsequent steps.

### Step 4: Add the SQL Role to the New Node.

To add a role, you must be a system-level user. Execute the following SQL statement from the SQL prompt, replacing `<NODE_NAME_OF_THE_NEW_NODE>` with the new node name.

SQL

```
ALTER NODE "<NODE_NAME_OF_THE_NEW_NODE>" ADD ROLE sql;
```

### Step 5: Add the Administrator Role. (Only for SQL Nodes with the Administrator Role)

If the node had the Administrator Role in Step 1, then add the Administrator Role back to the node. Execute the following SQL statement from the SQL prompt, replacing `<NODE_NAME_OF_THE_NEW_NODE>` with the new node name.

SQL

```
ALTER NODE "<NODE_NAME_OF_THE_NEW_NODE>" ADD ROLE admin;
```

### Step 6: Restart the Node.

Restart the `rolehostd` process on the replacement node by running this command at the shell terminal on the replacement node.

Shell

```
sudo systemctl restart rolehostd
```

## Loader Node Replacement Procedure

## Step 1: Remove the Failed Loader Node from the Ocient System.

Delete the node using the `DROP NODE` SQL statement, replacing `loader0` with the name of your node.

SQL

```
DROP NODE "loader0";
```

> ⚠ If the failed node still exists in the Ocient System, the system does not add the replacement node.

## Step 2: Register the New Node with the Ocient System.

Follow the **Bootstrapping Node Procedure** to register the new node.

When bootstrapping the replacement node, you can reuse the original node name or assign a new one. The node name of the newly registered node is used in subsequent steps.

## Step 3: Add the `streamloader` Role to the New Node.

To add a role, you must be a system-level user. Execute the following SQL statement, replacing `<NODE_NAME_OF_THE_NEW_NODE>` with the new node name.

SQL

```
ALTER NODE "<NODE_NAME_OF_THE_NEW_NODE>" add role streamloader;
```

> ⓘ When adding the `streamloader` role, the node must be restarted if it is already running in order for the change to take effect.

## Step 4: Configure the LAT Service.

Stop the LAT service by executing the following command at the shell prompt.

Shell

```
sudo systemctl stop lat
```

The LAT server configuration should be restored from the previous configuration. If a backup is unavailable, please contact Ocient Support for assistance or reference the other LAT configuration on the cluster to modify the default files.

- Copy the `lat.conf` backup file to `/etc/lat/lat.conf`.
- Copy the `log4j2.xml` backup file to `/etc/lat/log4j2.xml`.

Ensure that these two files have the appropriate ownership and permissions by executing the following commands.

Shell

```
chown lat:lat /etc/lat/lat.conf /etc/lat/log4j2.xml
chmod 644 /etc/lat/lat.conf /etc/lat/log4j2.xml
```

## Step 5: Restart the Node.

Restart the `rolehostd` process on the replacement node by running this command at the shell terminal on the replacement node.

Shell

```
sudo systemctl restart rolehostd
```

Start the LAT service.

Shell

```
sudo systemctl start lat
```

## Step 6: Update the LAT Pipeline if Required.

If a continuously streaming pipeline such as loading from Apache® Kafka® is operating on the Ocient System, then the Ocient System requires you to update the restored LAT to

run the same pipeline to restore full loading throughput. This process is different if a long-running File Load is in process.

### Kafka streaming pipeline procedure

| Pipeline Type | Procedure |
|---|---|
| Kafka Streaming Pipeline | 1. From the LAT Client, create the pipeline on the new LAT Node. This ensures the pipeline_id matches the existing LAT processes. |
| | 2. Start the pipeline on the new LAT Node. The new Loader Node joins the existing Loader Nodes, and the load automatically rebalances across all participating Loaders with the same `pipeline_id` |

### File load pipeline

| Pipeline Type | Procedure |
|---|---|
| File Load Pipeline | File loads from sources like S3, local file system, or NFS require rebalancing of partitions in the event that a node is lost or added back to an Ocient System.<br><br>In the event a node is lost, it is recommended that a rebalance is performed and the file load completes using the remaining nodes. The newly added node is not expected to participate in an already active file load. |

# Foundation Node Replacement Procedure

## Step 1: Register the New Node with the Ocient System.

Follow the **Bootstrapping Node Procedure** to register the new node. When bootstrapping the new node, you can reuse the original node name or assign a new one. This tutorial uses the node name of the newly registered node in subsequent steps. These examples use `foundation_new` for the new node name.

> If you want to reuse the original node name (the name of the node being removed), you must first rename the original node to prevent conflict. For example, if the original node was named `foundation_original`, this can be performed with the SQL statement `ALTER NODE "foundation_original" RENAME TO "foundation_to_drop";`

## Step 2: Add the New Node to a Specific Storage Cluster.

To operate as a Foundation Node, the node must be added to a storage cluster. To add a node to a storage cluster, you must be a system-level user. Execute the following SQL statement from the SQL prompt by replacing `storage_cluster_1` and `foundation_new` with your storage cluster name and node name, respectively.

SQL

```
ALTER CLUSTER "storage_cluster_1" ADD PARTICIPANTS "foundation_new";
```

## Step 3: Restart the New Node.

Restart the `rolehostd` process on the new node by running this command at the shell terminal on the new node.

Shell

```
sudo systemctl restart rolehostd
```

The node should now be operational.

## Step 4: Remove the Failed Foundation Node from the Ocient System.

Remove the original node from all clusters to which it belongs. For example, if the existing node is `foundation_original` and your storage cluster name is `storage_cluster_1`, execute the following SQL statement.

SQL

```
ALTER CLUSTER "storage_cluster_1" DROP PARTICIPANTS "foundation_original";
```

Delete the node using the `DROP NODE` SQL statement, replacing `foundation_original` with the name of your node.

SQL

```
DROP NODE "foundation_original";
```

> ⚠ If you renamed the failed original node in Step 1, be sure to use the correct name when dropping from the storage cluster and dropping the node.

### Step 5: Rebuild Segments.

In most cases, after removing the original node, administrators follow the **Guide to Rebuilding Segments** to rebuild segments that were on the replaced Foundation Node.

## Metadata Node Replacement Procedure

A Metadata Node is a node that only performs the Administrator Role.

### Step 1: Remove the Failed Administrator Node from the Ocient System.

Delete the node using the `DROP NODE` SQL statement by replacing `standaloneAdmin00` with the name of your node.

SQL

```
DROP NODE "standaloneAdmin00";
```

If the failed node still exists in the Ocient System, the system does not add the replacement node.

### Step 2: Register the New Node with the Ocient System.

Follow the **Bootstrapping Node Procedure** to register the new node.

When bootstrapping the replacement node, you can reuse the original node name or assign a new one. This tutorial uses the node name of the newly registered node in subsequent steps.

### Step 3: Add the Administrator Role to the New Node.

To add a role, you must be a system-level user. Execute the following SQL statement from the SQL prompt, replacing `<NODE_NAME_OF_THE_NEW_NODE>` with the new node name.

© 2026 Ocient, Inc

SQL

```
ALTER NODE "<NODE_NAME_OF_THE_NEW_NODE>" add role admin;
```

### Step 4: Restart the Node.

Restart the `rolehostd` process on the replacement node by running this command at the shell terminal on the replacement node.

Shell

```
sudo systemctl restart rolehostd
```

## Bootstrapping Node Procedure

To add a node to the system, follow these steps after meeting the prerequisites described in **Ocient System Bootstrapping**. These steps summarize the bootstrapping process.

> All prerequisites should be validated prior to bootstrapping. Ensure that you have set the correct credentials in the `bootstrap.conf` file. Generate a `nodeToken` with the `GET NODE TOKEN` SQL statement for secure authentication. Each token is single-use and expires after 15 minutes by default, so generate it shortly before starting the node. Also, you must specify any advanced configuration parameters in the `bootstrap.conf` file.

**Step 1:** Create a `/var/opt/ocient/bootstrap.conf` file on the node by replacing the `<FIRST_NODE_ADDRESS>` with the IP or Hostname of a node running the Administrator Role.

YAML

```
adminHost: <FIRST_NODE_ADDRESS>
nodeToken: <token_from_GET_NODE_TOKEN>
```

> You can also use `adminUserName` and `adminPassword` instead of `nodeToken`, but this approach is deprecated. Use node tokens for improved security. If the password for the system administrator has changed, set the correct username and password in `bootstrap.conf`.

**Step 2**: Start the new node.

Shell

```
sudo systemctl start rolehostd
```

This action accepts the node into the system and prepares it for role assignment.

> If the join fails, generate a new token before retrying. Check for a stale node entry from the failed attempt, and then execute the `DROP NODE` SQL statement to remove it before starting the node again.

# Backup and Restore

Back up and restore Ocient databases using the BACKUP and RESTORE SQL statements to protect data, recover from failures, and migrate between environments.

Ocient® can back up and restore a single node or a multi-node system. The backup and restore procedures can replace a node in an existing Ocient cluster due to an OS drive failure or hardware upgrade.

⚠ Exact backup and restore procedures depend on the disk layout of your Ocient nodes. Consult Ocient Support or the system administrator who installed your Ocient cluster to determine the best backup strategy for your deployment.

# Log Monitoring

Monitor logs in an Ocient System to detect errors, audit access, and diagnose performance problems across SQL Nodes, Foundation Nodes, and data pipelines.

> ⚠ Contact Ocient® Support for assistance before altering the system logging configuration in the `rolehostd.conf` file.

The OcientAIQ™ Unified Data Platform logs events using these severities:

- `Error`
- `Warn`
- `Info`
- `Verbose`
- `Debug`
- `Extended Debug`

By default, the data warehouse creates the text log file `/var/opt/ocient/rolehostd.log` and logs events at the `Info` level and above.

Database logging supports extensive customization and integration with third-party tools. You can customize using the `rolehostd` config file. The database can return events in text, JSON, or Graylog® Extended Log Format (GELF) formats, or the database can return events in a file, to standard output ( `stdout` ), or to a UDP port. You can customize based on the log source.

## Log Formats

The default log format is text. These are some example log entries.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Text

```
[2020-06-09T18:11:25.701594][ INFO][role001] roleHost: All roles started
[2020-06-09T18:11:25.701881][ INFO][role001] roleHost: Starting all endpoints
[2020-06-09T18:11:25.701925][ INFO][role001] roleHost: Starting endpoint 127.0.0.1:
[2020-06-09T18:11:25.704905][ INFO][role001] roleHost: Starting endpoint 127.0.0.1:
[2020-06-09T18:11:25.708437][ INFO][tcpU008] roleHost: All endpoints started
[2020-06-09T18:11:25.709236][ INFO][role001] host: ------------------------------
[2020-06-09T18:11:25.709286][ INFO][role001] host: Rolehostd successfully started
[2020-06-09T18:11:25.709305][ INFO][role001] host: ------------------------------
```

Each log line contains the time, severity, thread, and the source of the log (for example, `roleHost` or `host`).

JSON-formatted logs contain the same information but in a structured format.

JSON

```
{"sys":"oc1.admin0", "timestamp":1591726285.701594684, "thread":"role001", "lvl":"
{"sys":"oc1.admin0", "timestamp":1591726285.701881144, "thread":"role001", "lvl":"
{"sys":"oc1.admin0", "timestamp":1591726285.701925519, "thread":"role001", "lvl":"
{"sys":"oc1.admin0", "timestamp":1591726285.704905192, "thread":"role001", "lvl":"
{"sys":"oc1.admin0", "timestamp":1591726285.708437413, "thread":"tcpU008", "lvl":"
{"sys":"oc1.admin0", "timestamp":1591726285.709236006, "thread":"role001", "lvl":"
{"sys":"oc1.admin0", "timestamp":1591726285.709286683, "thread":"role001", "lvl":"
{"sys":"oc1.admin0", "timestamp":1591726285.709305246, "thread":"role001", "lvl":"
```

GELF-formatted log entries follow the format defined on the **GELF via UDP** page. This is an example GELF format.

JSON

```
{"host":"oc1.admin0", "version": "1.1", "timestamp":1591726285.701594684, "_thread"
{"host":"oc1.admin0", "version": "1.1", "timestamp":1591726285.701881144, "_thread"
{"host":"oc1.admin0", "version": "1.1", "timestamp":1591726285.701925519, "_thread"
{"host":"oc1.admin0", "version": "1.1", "timestamp":1591726285.704905192, "_thread"
{"host":"oc1.admin0", "version": "1.1", "timestamp":1591726285.708437413, "_thread"
{"host":"oc1.admin0", "version": "1.1", "timestamp":1591726285.709236006, "_thread"
{"host":"oc1.admin0", "version": "1.1", "timestamp":1591726285.709286683, "_thread"
{"host":"oc1.admin0", "version": "1.1", "timestamp":1591726285.709305246, "_thread"
```

© 2026 Ocient, Inc

The database always returns message content in the `short_message` field of the GELF format.

This table maps Ocient severities to GELF system log (syslog) severities.

| Ocient Severity | Syslog Severity | Syslog Numeric Value |
|---|---|---|
| `Error` | `Error` | 3 |
| `Warn` | `Warning` | 4 |
| `Info` | `Notice` | 5 |
| `Verbose` | `Info` | 6 |
| `Debug` and `Extended Debug` | `Debug` | 7 |

# Log Appenders

A log appender is the destination for log entries. The database can send log entries to a file, a UDP port, or to `stdout`.

When logs are sent to the file appender, they grow continuously unless you use the `truncate` option in the configuration. You can use tools such as `logrotate` to manage log files.

This is a sample `logrotate` configuration.

Text

```
/var/opt/ocient/log/rolehostd.log {
   rotate 5
   daily
   delaycompress
   compress
   copytruncate
   missingok
   minsize 1M
   maxsize 100M
}
```

Test the UDP appender using the Linux® `netcat` command.

LINUX

```
$ netcat -ul 9000
```

# Log Configuration

An Ocient System supports various logging settings to meet different needs.

Set log configuration settings in `rolehostd.conf`, a YAML file normally found in the system `/var/opt/ocient/` directory. You can change configuration settings to suit your system logging needs in this file.

For information on checking the status of nodes, see **Statistics Monitoring**.

> If you are using an Ocient Simulator, logging behavior and directories might differ from these descriptions.
>
> For details on how logging works in the Ocient Simulator, see **Simulator Logging**.

## `rolehostd` Example

This is an abbreviated `rolehostd.conf` example in YAML format. Normally, this file contains other system configurations, but this tutorial focuses on the `loggingConfig` section, which defines logging behaviors and scopes.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

YAML

```yaml
loggingConfig:
    '':  # Default scope (all logs)
        appender:
        logFilePath: /path/to/rolehostd.log
    appenders:
    - appender:
        allowLevel: warn
        logFilePath: /path/to/error.log
    - appender:
        allowLevel: warn
        format: json
        logFilePath: /path/to/error.json

    dump:  # Dump-specific logs
        allowLevel: debug
        appender:
            logFilePath: /path/to/dump.log

    query:  # Query-specific logs
        allowLevel: info
        appender:
            format: json
            logFilePath: /path/to/query.json

    security:  # Security-specific logs
        allowLevel: info
        appender:
            format: json
            logFilePath: /path/to/security.json

    network-logs:  # Example network logging
        allowLevel: info
        appender:
            type: UDP
            server: graylog.internal
            port: 12201
            format: gelf
            compressed: true
```

## Scope Definition

The top level of the logging configuration is the scope, which determines the corresponding log sources for each configuration setup.

### Default Scope

An empty scope string ( `''` ) applies its configuration settings to all log entries the system returns.

### Named Scopes

Named scopes apply to log entries where the first component matches the name. Useful scopes include:

- `query` — Contains information on all queries and statements executed on the system, including users, time, and other details.
- `security` — Contains information on all connections made to the system, successful or unsuccessful.
- `dump` — Contains information on system failures.

## `allowLevel`

The `allowLevel` parameter specifies which severity levels of logs to capture.

YAML

```yaml
allowLevel: value
```

Severity `value` definitions are:

- `debug` — Most verbose (includes all logs).
- `info` — Includes informational messages and greater severities.
- `verbose` — More verbose than the `info` severity.
- `warn` — Includes warnings and errors only.
- `error` — Includes only error messages.

## `appender`

Appenders define the format and directory where the database sends log files. You can configure either one or many appenders for each scope.

### Single Appender

For a single appender, use the `appender` key.

YAML

```yaml
appender:
    key: value
    [ ... ]
```

### Multiple Appenders

For multiple output destinations, use the `appenders` key, followed by a list of `appender` keys.

YAML

```yaml
appenders:
- appender:
    key: value
    [ ... ]
- appender:
    key: value
    [ ... ]
[ -...]
```

## `format`

Defines the output format of the log files of an appender.

YAML

```yaml
appender:
    format: format_type
```

Supported `format_type` values are:

- `text` — Human-readable text format (default).
- `json` — Structured JSON format.
- `gelf` — GELF format for integration with Graylog.

### `logFilePath`

Defines the destination directory for log files of the appender. The `directory` value is a file path for the appender log files, for example: `/path/to/rolehostd.log`.

YAML

```yaml
appender:
    logFilePath: directory
```

### `type`

Determines whether the system submits error logs through `stdout` or to a separate server using a TCP or UDP protocol.

YAML

```yaml
appender: # standard output example
    type: stdout

appender: # UDP example
    type: UDP
    server: graylog-server.example.com
    port: 12201
    chunkSize: 1024  # Optional
    compressed: true  # Optional

appender: # TCP example
    type: TCP
    server: 192.158.1.38
    port: 12201
```

### `server`

Required for TCP or UDP types.

The destination DNS name or IP address where the database sends log entries.

YAML

```yaml
appender:
    server: 192.158.1.38
```

`port`

> Required for TCP or UDP types.

The port where the database sends log entries. The default value is `9000`.

YAML

```yaml
appender:
    port: 12201
```

`chunkSize`

> Optional for UDP type.

The largest packet size in bytes that the system sends to the server. The database discards log entries larger than this value.

YAML

```yaml
appender:
    chunkSize: 1024
```

`compressed`

> Optional for UDP type.

If you set this option to `true`, the system compresses packets. For details about log compression, see the **GELF documentation**. Otherwise, the packets are uncompressed.

YAML

```yaml
appender:
    compressed: true
```

### `truncate`

If you set this option to `true`, the system truncates the log file when the system starts. Otherwise, the system appends new logs to the file. The default value is `false`.

YAML

```yaml
appender:
    truncate: true
```

### `redactions`

You can redact data in logs at the SQL statement level using the optional `redactions` configuration. Enabling redaction creates another version of the logs with redacted SQL text. The `redactions` configuration value is `statement` for the redaction of part of the statement.

YAML

```yaml
appender:
    redactions:
    - statement # Optional
```

### `rolehostd` Log Redaction Example

This abbreviated `rolehostd.conf` file configuration enables log redaction at the statement level for both the `rolehostd.log` and `query.json` log files.

YAML

```yaml
loggingConfig:
    ? '':
    appenders:
    - appender:
        logFilePath: /var/opt/ocient/logs/rolehostd.log
    - appender:
        logFilePath: /var/opt/ocient/logs/rolehostd_redacted.log
        redactions:
        - statement
    query:
        allowLevel: info
        appenders:
        - appender:
            format: json
            logFilePath: /var/opt/ocient/logs/query.json
        - appender:
            format: json
            logFilePath: /var/opt/ocient/logs/query_redacted.json
            redactions:
            - statement
```

# Statistics Monitoring

Monitor Ocient System statistics, including query throughput, resource utilization, and pipeline metrics, to maintain visibility into operational performance.

The OcientAIQ™ Unified Data Platform maintains many internal statistics. You can access the statistics on each node in the database using a REST interface that listens on port 9090 by default. For the endpoints, see **System Information REST Endpoints**.

For Prometheus®-compatible monitoring tools, see the **Prometheus Metrics Endpoint**, which serves the same metrics in OpenMetrics text format with label-based filtering.

Explore the statistics using a command such as curl.

CURL

```
curl http://oc1-lts0:9090/v1/stats
```

The resulting statistics return in JSON format. This excerpt shows only a partial list of the results.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

JSON

```
[{
    {
        "name": "localStorageService.device[SDM00001A616].spaceFree",
        "node": "oc1-lts0",
        "time": 1591737983812323,
        "units": "bytes",
        "value": 356599726080
    },
    {
        "name": "localStorageService.device[SDM00001A616].spaceFreePct",
        "node": "oc1-lts0",
        "time": 1591737983812323,
        "units": "none",
        "value": 4631469015491373042
    },
    {
        "name": "localStorageService.device[SDM00001A616].spaceTotal",
        "node": "oc1-lts0",
        "time": 1591737983812323,
        "units": "bytes",
        "value": 800149299200
    }
}]
```

Because each node can produce a very large number of statistics, the REST interface supports wildcard filtering.

Return statistics that match the regular expression `^localStorageService*` using this curl command.

CURL

```
curl -G --data-urlencode 'filter=^localStorageService*' http://oc1-lts0:9090/v1/s
```

The resulting subset of statistics returns in JSON format.

## Retrieve Statistics Using Telegraf

Telegraf™ is a commonly used monitoring tool. This example shows the configuration file for Telegraf that gathers statistics from a database node where the statistic name includes `localStorageService`.

Text

```
; Read formatted metrics from one or more HTTP endpoints
[[inputs.http]]
  interval = "30s"

  urls = [
    "http://oc1-lts0:9090/v1/stats?filter=localStorageService"
  ]

  ; HTTP method
  method = "GET"

  data_format = "json"
  json_name_key = "name"
  json_time_key = "time"
  json_time_format = "unix_us"
  json_timezone = "America/Chicago"
  tag_keys = [
    "node",
    "silo",
    "core"
  ]
  [inputs.http.tags]
    source = "rolehostd"
```

# Prometheus Metrics Endpoint

Access Ocient System metrics in Prometheus exposition format using the /metrics endpoint for integration with Prometheus, Grafana, Datadog, and other monitoring tools.

The OcientAIQ™ Unified Data Platform exposes a Prometheus®-compatible `/metrics` endpoint on each node that serves system performance metrics in the **OpenMetrics** text format. Use this endpoint to integrate with Prometheus, Grafana®, Datadog®, and other monitoring tools that support Prometheus scraping.

The `/metrics` endpoint is available on the same **REST interface** (port 9090) as the legacy `/v1/stats` JSON endpoint.

## Access the Endpoint

Query the endpoint using `curl` or any HTTP client.

CURL

```
curl http://oc1-lts0:9090/metrics
```

The response uses the Prometheus text exposition format.

Output

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Prometheus

```
# HELP jemalloc_stats_bytes jemalloc: memory statistics
# TYPE jemalloc_stats_bytes gauge
# UNIT jemalloc_stats_bytes bytes
jemalloc_stats_bytes{type="active"} 1073741824
jemalloc_stats_bytes{type="allocated"} 1048576000
jemalloc_stats_bytes{type="resident"} 1610612736
# HELP local_storage_service_free_space_bytes Free space on storage device in bytes
# TYPE local_storage_service_free_space_bytes gauge
# UNIT local_storage_service_free_space_bytes bytes
local_storage_service_free_space_bytes{device="SDM00001A616"} 356599726080
# HELP cmdcomp_queries Number of queries by state
# TYPE cmdcomp_queries gauge
cmdcomp_queries{status="execution"} 5
cmdcomp_queries{status="parsing"} 2
cmdcomp_queries{status="queue"} 12
```

## Query Parameters

The `/metrics` endpoint supports these query parameters to filter the response.

| Parameter | Type | Default | Description |
|---|---|---|---|
| `level` | string | `info` | Filter metrics by visibility level with these supported values: `info`, `debug`, or `default`. |
| `filter` | string | None | Regular expression pattern to match metric names. The endpoint returns only metrics whose names match the pattern. |

### Filter by Level

Return only production-level ( `info` ) metrics. The Ocient® system exports these metrics to Datadog for production monitoring.

CURL

```
curl "http://oc1-lts0:9090/metrics?level=info"
```

Include debug-level metrics for troubleshooting.

CURL

```
curl "http://oc1-lts0:9090/metrics?level=debug"
```

### Filter by Name

Use the `filter` parameter with a regular expression to return only metrics whose names match the pattern. Narrow the response to a specific functional area instead of retrieving all available metrics.

Return only query-processing metrics by matching the `cmdcomp` prefix.

CURL

```
curl -G --data-urlencode "filter=^cmdcomp" http://oc1-lts0:9090/metrics
```

Return all storage-related metrics.

CURL

```
curl -G --data-urlencode "filter=^local_storage_service" http://oc1-lts0:9090/metri
```

Combine both parameters to return only `info`-level ingestion metrics.

CURL

```
curl -G --data-urlencode "filter=^stream_loader" "http://oc1-lts0:9090/metrics?leve
```

## Metric Types

Each metric has a type that determines how you interpret and aggregate it.

| Type | Description | Example |
| --- | --- | --- |
| `counter` | A monotonically increasing value that resets only on process restart. Use `rate()` or `increase()` in queries. | `stream_loader_api_push_rows_requests_total` |

| Type | Description | Example |
| --- | --- | --- |
| `gauge` | A value that can increase or decrease. Represents a current measurement. | `cmdcomp_queries{status="execution"}` |

## Metric Units

When a metric has a defined unit, the system appends the unit name as a suffix to the metric name using Prometheus conventions.

| Unit | Suffix | Description |
| --- | --- | --- |
| Bytes | `_bytes` | Memory, disk space, and data transfer sizes. |
| Seconds | `_seconds` | Durations and time measurements. |
| Percent | `_percent` | Ratios expressed as percentages (0–100). |
| None | No suffix | Dimensionless counts or ratios. |

## Metric Labels

Labels provide dimensional metadata that distinguishes different instances of the same metric. For example, `cmdcomp_queries` uses a `status` label to differentiate query states.

Prometheus

```
cmdcomp_queries{status="execution"} 5
cmdcomp_queries{status="parsing"} 2
cmdcomp_queries{status="queue"} 12
```

Common labels include these categories.

| Label | Description | Example Values |
| --- | --- | --- |
| `device` | Storage device identifier | Device Universally Unique IDentifier (UUID) |
| `protocol` | Internal protocol name | `storage_cluster`, `vm`, or `health` |
| `status` | Operation or query state | `success`, `error`, or `execution` |
| `type` | Metric subtype or category | `active`, `allocated`, or `page` |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Label | Description | Example Values |
| --- | --- | --- |
| `stage` | Pipeline processing stage | `batch_preparation` or `segment_transfer` |
| `action` | Protocol action name | `on_get_segment_data` or `activate_segment` |

# Metric Categories

This table summarizes the categories of metrics available with the `/metrics` endpoint.

| Category | Metric Name Prefix | Description |
| --- | --- | --- |
| Query processing | `cmdcomp_*` | Query states, metadata cache operations, SQL Node load, and server connections. |
| Storage devices | `local_storage_service_*` | Disk free space, total space, NVMe SMART health attributes, I/O timeouts, and device status. |
| Ingestion | `stream_loader_*` | Push rows API request counts, data durability, pipeline stage operations, and durations. |
| Memory | `jemalloc_stats_*`, `memory_heap_*`, `memory_huge_*` | Memory allocator statistics and per-subsystem memory usage. |
| Query execution | `vm_*` | Active queries, datablock router throughput, scheduler state, and dispatch queue events. |
| Virtual segments | `virtual_segment_*`, `virtual_read_cache_*` | Segment rebuild activity, read cache hit rates, and block counts. |
| Storage cluster | `storage_cluster_*` | Segment counts, OSN lifecycle, and cluster data statistics. |
| Protocol timing | `protocol_time_*`, `protocol_actions_*` | Internal protocol dispatch delays and action durations. |
| Raft consensus | `protocol_raft_*`, `raft_engine_*` | Raft log sizes, snapshot sizes, participant state, and leader method timing. |
| Disk spill | `disk_based_operator_instance_*` | Bytes spilled to disk during query execution. |
| System configuration | `system_configuration_store_*` | Configuration refresh durations and operation counts. |
| Health | `operator_summary_oldest_age_*`, `healthProtocolInstance_*` | Oldest running operator age and distributed task counts. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Category | Metric Name Prefix | Description |
| --- | --- | --- |
| TKT pipeline | `tkt_*`, `partition_provider_*` | Pipeline operator I/O buffer stalls and emits rows. |

# Key Metrics Reference

These metric families capture monitoring system health, query performance, ingestion throughput, and storage capacity.

## Query States and Connections

These metrics provide visibility into the query lifecycle and client connectivity on each SQL Node.

### `cmdcomp_queries`

The number of queries currently in each processing state on this node. Use this metric to monitor query queue depth, identify bottlenecks in the compilation pipeline, and detect query pile-ups.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | None (count) |
| Labels | `status` |

Label values for `status`.

| Value | Description |
| --- | --- |
| `queue` | Queries waiting to begin processing. |
| `parsing` | Queries that the database parses from SQL text. |
| `compilation` | Queries that the database compiles into execution plans. |
| `optimization` | Queries the query planner optimizes. |
| `validation` | Queries undergoing validation before execution. |
| `vm_initialization` | Queries initializing the virtual machine execution state. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Value | Description |
| --- | --- |
| `execution` | Queries actively executing. |

This example alerts when the database queues more than 50 queries.

PromQL

```
cmdcomp_queries{status="queue"} > 50
```

### `cmdcomp_server_connections`

The number of active client connections to the command compiler server on this node. A sudden drop can indicate a network issue, whereas a sustained increase can indicate connection leaks.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | None (count) |
| Labels | None |

### `cmdcomp_sql_node_load`

A composite metric representing the total SQL Node load across all nodes. Use this metric to assess whether the query workload is balanced across the cluster.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | None |
| Labels | None |

### `cmdcomp_metadata_cache_operations`

Counts of metadata cache operations by result type. A low hit rate (high misses relative to requests) might indicate cache pressure or frequent schema changes.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Attribute | Value |
| --- | --- |
| Type | `counter` |
| Unit | None (count) |
| Labels | `type` |

This table describes label values for `type`.

| Value | Description |
| --- | --- |
| `hit` | Metadata found without recomputation (cache hit). |
| `misses` | Metadata fetched or recomputed (cache miss). |
| `requests` | Total requests to the metadata cache. |

This example calculates the metadata cache hit rate over a 5-minute period.

PromQL

```
rate(cmdcomp_metadata_cache_operations{type="hit"}[5m])
  /
rate(cmdcomp_metadata_cache_operations{type="requests"}[5m])
```

## Ingestion Metrics

These metrics track the data ingestion pipeline from API request receipt through segment generation and transfer.

### `stream_loader_api_push_rows_requests`

Total count of push-row API requests that the Loader Node receives by outcome. Use this metric to monitor ingestion request volume and error rates.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Attribute | Value |
| --- | --- |
| Type | `counter` |
| Unit | None (count) |
| Labels | `status` |

This table describes label values for `status`.

| Value | Description |
| --- | --- |
| None | Total requests (all outcomes). |
| `success` | Requests that completed successfully. |
| `error` | Requests that failed. |
| `rate_limit_exceeded` | Requests rejected due to rate limiting. |

This example calculates the error rate as a percentage over a 5-minute period.

PromQL

```
rate(stream_loader_api_push_rows_requests{status="error"}[5m])
  /
rate(stream_loader_api_push_rows_requests[5m]) * 100
```

### `stream_loader_api_row_count`

Total number of rows pushed using the API. Use this metric along with the `stream_loader_api_push_rows_requests` metric to calculate the average batch size.

| Attribute | Value |
| --- | --- |
| Type | `counter` |
| Unit | None (count) |
| Labels | None |

### `stream_loader_data_durable_bytes`

Bytes that the Loader Node has made durable (persisted) by the storage tier.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | Bytes |
| Labels | `type` |

This table describes the label values for `type`.

| Value | Description |
| --- | --- |
| `api` | Durable bytes received from the API. |
| `page` | Durable bytes written to pages. |

### `stream_loader_data_row_count`

Current number of rows in the Loader Node by durability status.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | None (count) |
| Labels | `durability` |

This table describes label values for `durability`.

| Value | Description |
| --- | --- |
| `durable` | Rows persisted to storage. |
| `non_durable` | Rows still in-memory awaiting persistence. |

### `stream_loader_operations_count`

Counts of pipeline stage operations by stage and outcome. Use this metric to identify the stage in the ingestion pipeline that experiences the most errors or throughput.

© 2026 Ocient, Inc Ocient Proprietary and Confidential

| Attribute | Value |
| --- | --- |
| Type | `counter` |
| Unit | None (count) |
| Labels | `stage` or `status` |

This table describes label values for `stage`.

| Value | Description |
| --- | --- |
| `batch_preparation` | Prepare raw data into batches. |
| `segment_generation` | Generate storage segments from batches. |
| `segment_grouping` | Group segments for transfer. |
| `segment_partitioning` | Partition segments across the cluster. |
| `segment_transfer` | Transfer segments to storage nodes. |

This table describes label values for `status`.

| Value | Description |
| --- | --- |
| None | Total operations. |
| `success` | Successful completions. |
| `error` | Failed operations. |

### `stream_loader_operations_duration`

Most recent duration, in seconds, of each pipeline stage. Use this metric to identify slow stages in the ingestion pipeline.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | Seconds |
| Labels | `stage` |

## Disk Health and Space

These metrics monitor storage device capacity, health, and performance on each Foundation Node.

### `local_storage_service_free_space_bytes`

Free space, in bytes, on each storage device. Monitor this value to detect nodes approaching full capacity.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | Bytes |
| Labels | `device` |

This example finds devices with less than 10% free space.

PromQL

```
local_storage_service_space_free_pct < 10
```

### `local_storage_service_total_space_bytes`

Total capacity, in bytes, of each storage device.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | Bytes |
| Labels | `device` |

### `local_storage_service_space_free_pct`

Percentage of free space on each storage device (0–100).

| Attribute | Value |
| --- | --- |
| Type | `gauge` |

| Attribute | Value |
| --- | --- |
| Unit | Percent |
| Labels | `device` |

### `local_storage_service_io_timeouts`

Count of NVMe I/O timeouts by the `opcode` category. Any non-zero value warrants investigation as it might indicate drive degradation.

| Attribute | Value |
| --- | --- |
| Type | `counter` |
| Unit | None (count) |
| Labels | `opcode` |

This table describes label values for `opcode`.

| Value | Description |
| --- | --- |
| `admin` | Administrator command timeouts. |
| `read` | Read command timeouts. |
| `write` | Write command timeouts. |
| `dsm` | Data set management (TRIM or deallocate) timeouts. |
| `other` | Other `opcode` timeouts. |

### `local_storage_service_device_endurance`

Estimated percentage of device life used (0–100). As this value approaches 100, schedule the drive for replacement.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | Percent |
| Labels | `device` |

`local_storage_service_available_spare_pct`

Available spare capacity on the NVMe device, normalized to a percentage. When this value drops below the threshold (see the `local_storage_service_available_spare_threshold_pct` metric), the device controller asserts a warning.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | Percent |
| Labels | `device` |

`local_storage_service_crc_errors`

Cumulative count of CRC errors detected by the device. A rising count indicates potential data integrity issues on the link between the host and drive.

| Attribute | Value |
| --- | --- |
| Type | `counter` |
| Unit | None (count) |
| Labels | `device` |

## Active Queries and Operator Age

These metrics provide high-level visibility into query execution activity and help detect stuck or long-running operations.

`vm_active_queries_count`

Total number of queries currently executing on the virtual machine of this node. Use this metric to gauge overall query concurrency and correlate with resource consumption.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | None (count) |
| Labels | None |

This example alerts when active queries exceed the expected concurrency limit.

PromQL

```
vm_active_queries_count > 200
```

### `operator_summary_oldest_age_seconds`

Age, in seconds, of the oldest currently running operator instance on this node. A large value might indicate a stuck query or an operation waiting on an unavailable resource.

| Attribute | Value |
| --- | --- |
| Type | `gauge` |
| Unit | Seconds |
| Labels | None |

This example alerts when any operator has been running for more than one hour.

PromQL

```
operator_summary_oldest_age_seconds > 3600
```

### `disk_based_operator_instance_bytes_spilled`

Total bytes that query operators have spilled to disk when the database exceeds in-memory budgets. A high spill volume indicates that queries are exceeding available memory and resorting to disk-based processing, which is significantly slower.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Attribute | Value |
| --- | --- |
| Type | `counter` |
| Unit | Bytes |
| Labels | `compression` |

This table describes label values for `compression`.

| Value | Description |
| --- | --- |
| `compressed` | Bytes written to disk after compression. |
| `uncompressed` | Logical bytes spilled before compression. |

This example monitors the spill rate in bytes per second.

PromQL

```
rate(disk_based_operator_instance_bytes_spilled{compression="uncompressed"}[5m])
```

## Configure Prometheus Scraping

If you run a Prometheus server, you can configure it to periodically scrape the `/metrics` endpoint on each Ocient node. Prometheus stores the scraped metrics in its time series database, making them available for PromQL® queries and Grafana dashboards.

Add a scrape job to your `prometheus.yml` configuration file. List every Ocient node as a target and set `metrics_path` to `/metrics`. The `params` section passes query parameters, such as `level`, with each scrape request.

prometheus.yml

```
scrape_configs:
  - job_name: 'ocient'
    scrape_interval: 30s
    params:
      level: ['info']
    static_configs:
      - targets:
          - 'oc1-lts0:9090'
          - 'oc1-lts1:9090'
          - 'oc1-sql0:9090'
    metrics_path: '/metrics'
```

After you save and reload the Prometheus configuration, the targets appear on the Prometheus **Status > Targets** page. Prometheus begins collecting metrics at the configured `scrape_interval` interval.

## Configure the Datadog Agent

If you use Datadog instead of Prometheus, Ocient provides an official Datadog integration that scrapes the same `/metrics` endpoint and forwards metrics to the Datadog cloud platform. For details, see **Datadog Integration**.

## Example Queries

These example PromQL queries demonstrate common monitoring use cases. You can execute them in the Prometheus expression browser, in a Grafana dashboard panel, or with any tool that supports PromQL.

### Disk Space Utilization

Calculate the percentage of free disk space on each storage device. A declining value indicates that the node is running low on storage and might need capacity planning or data retention adjustments.

PromQL

```
local_storage_service_free_space_bytes / local_storage_service_total_space_bytes *
```

### Query Queue Depth

Return the current number of queries waiting in the queue. A consistently high value might indicate that the system is under heavy query load or that additional SQL Nodes are needed to handle the workload.

PromQL

```
cmdcomp_queries{status="queue"}
```

### Loader Node Error Rate

Calculate the ratio of failed push-row API requests to total requests over the last 5 minutes. The `rate()` function converts the raw counter into a per-second rate. A rising error rate might indicate issues with the data source, schema mismatches, or pipeline configuration errors.

PromQL

```
rate(stream_loader_api_push_rows_requests_total{status="error"}[5m])
  /
rate(stream_loader_api_push_rows_requests_total[5m])
```

### Memory Allocator Pressure

Compare the amount of memory actively in use by `jemalloc` to the total memory mapped from the operating system. A ratio approaching 1.0 indicates that most mapped memory is in active use, which might signal memory pressure on the node.

PromQL

```
jemalloc_stats_bytes{type="active"} / jemalloc_stats_bytes{type="mapped"}
```

## Comparison with the Legacy `/v1/stats` Endpoint

This table compares the legacy `/v1/stats` endpoint features to the Prometheus metrics.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Feature | `/v1/stats` (Legacy) | `/metrics` (Prometheus) |
|---|---|---|
| Format | JSON | Prometheus text exposition |
| Naming | Dot-delimited (e.g., `localStorageService.device.spaceFree`) | Underscore-delimited with unit suffix (e.g., `local_storage_service_free_space_bytes`) |
| Labels | Encoded in metric name (e.g., `device[UUID]`) | Prometheus labels (e.g., `{device="UUID"}`) |
| Filtering | `filter` query parameter (regex) | `filter` and `level` query parameters |
| Tooling | Custom JSON parsers or Telegraf™ | Prometheus, Grafana, Datadog, or any OpenMetrics client |
| Level filtering | Not supported | `level=info\|debug\|default` |

Both endpoints remain available on port 9090 and serve the same underlying metric data.

# Datadog Integration

Monitor Ocient cluster health and query performance by collecting metrics with the official Datadog Ocient integration.

The OcientAIQ™ Unified Data Platform provides an official Datadog® integration that collects performance metrics from the Prometheus®-compatible `/metrics` **endpoint** and forwards them to the Datadog cloud platform. Use this integration to monitor cluster health, query performance, ingestion throughput, and storage capacity alongside your other infrastructure in Datadog.

For installation and general configuration instructions, see the **Datadog Ocient Integration** page. This page covers Ocient®-specific configuration guidance that supplements the Datadog documentation.

## Prerequisites

You must have:

- Datadog Agent version 7 or later installed on a host that can reach the Ocient cluster.
- Network access from the Datadog Agent host to port 9090 on each Ocient node that you want to monitor.
- The Ocient integration installed on the Agent ( `agent integration install -t datadog-ocient==1.0.0` ).

## Filter Metrics by Level

The Ocient `/metrics` endpoint supports a `level` query parameter that controls which metrics the endpoint returns. Append `?level=info` to the `openmetrics_endpoint` URL to limit collection to production-level metrics, reducing cardinality and Datadog cost. The supported levels are `info` (production metrics), `debug` (all metrics including internal diagnostics), and `default` (baseline set).

This configuration collects only `info` -level metrics from a single SQL Node.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

conf.d/ocient.d/conf.yaml

```yaml
instances:
  - use_openmetrics: true
    openmetrics_endpoint: http://oc1-sql0:9090/metrics?level=info
```

## Monitor Multiple Nodes

The integration scrapes one endpoint for each instance. To monitor an entire cluster, add one instance per node in the configuration file. Each Ocient node exposes its own metrics independently. SQL Nodes expose query lifecycle metrics ( `cmdcomp_*` ), while Foundation Nodes expose storage and ingestion metrics (e.g., `local_storage_service_*` , `stream_loader_*` ).

This configuration monitors one SQL Node `oc1-sql0` and two Foundation Nodes, `oc1-lts0` and `oc1-lts1` , in the same cluster, collecting `info` -level metrics from each.

conf.d/ocient.d/conf.yaml

```yaml
instances:
  - use_openmetrics: true
    openmetrics_endpoint: http://oc1-sql0:9090/metrics?level=info
  - use_openmetrics: true
    openmetrics_endpoint: http://oc1-lts0:9090/metrics?level=info
  - use_openmetrics: true
    openmetrics_endpoint: http://oc1-lts1:9090/metrics?level=info
```

## Name Metrics in Datadog

Metrics appear in Datadog with the prefix `ocient.` followed by the metric name from the `/metrics` endpoint. For example, the endpoint metric `cmdcomp_queries` becomes `ocient.cmdcomp_queries` in Datadog.

Datadog removes the `_total` suffix for counter metrics and replaces it with a `.count` suffix for submission. For example, `stream_loader_api_push_rows_requests_total` becomes `ocient.stream_loader_api_push_rows_requests.count` .

© 2026 Ocient, Inc

For a complete reference of available metrics, their types, labels, and descriptions, see the **Prometheus Metrics Endpoint — Key Metrics Reference**.

## Service Checks

The integration reports a service check named `ocient.openmetrics.health` that indicates the reachability of the configured `openmetrics_endpoint` endpoint. The `OK` value indicates successful scraping, whereas the `CRITICAL` value indicates the endpoint is unreachable.

## Troubleshooting

Troubleshoot common error messages when you work in Datadog:

- `Agent cannot reach the endpoint.` — Verify that the host running the Agent can connect to port 9090 on the target Ocient node. The `/metrics` endpoint does not require authentication. Execute this `curl` command on the Agent host to confirm that the endpoint is reachable and returns metric data.

  ```
  curl -s http://oc1-sql0:9090/metrics | head -5
  ```

  If the command returns metric lines starting with `#` (comment headers) or metric name-value pairs, the endpoint is accessible. An empty response or connection error indicates a network or firewall issue.

- `No metrics appear in Datadog.` — Execute the `agent check ocient` command and inspect the output for errors. Common issues include incorrect endpoint URLs, typos in the hostname or port, and firewall rules blocking port 9090.
- `High metric cardinality.` — Use the `level=info` query parameter to limit collection to production-level metrics. Alternatively, use the `exclude_metrics` option in the `conf.d/ocient.d/conf.yaml` file to drop high-cardinality metric families, such as `jemalloc_*`.
- `Metric names differ from the endpoint.` — Datadog applies the `ocient.` namespace prefix and converts counter suffixes. For details, see **Name Metrics in Datadog**.

# System Information REST Endpoints

Access Ocient system information through REST endpoints to query configuration, statistics, status, and version data for monitoring and automation use cases.

The OcientAIQ™ Unified Data Platform maintains many internal statistics. You can access the statistics on each node in the database using a REST interface that listens on port 9090 by default. For an overview of monitoring statistics, see **Statistics Monitoring**.

# Set Up System Monitoring with the TIG Stack and Kapacitor

Monitor an Ocient System with the TIG stack (Telegraf, InfluxDB, Grafana) and Kapacitor for metrics, dashboards, alerting, and capacity planning insight.

One method to monitor the OcientAIQ™ Unified Data Platform is to use the TIG (Telegraf™, InfluxDB® and Grafana®) Stack. While these instructions are specifically written for this toolset, you can also use this guide as the foundation to set up an alternate stack if necessary.

This guide uses InfluxDB, Telegraf, Kapacitor™, and Grafana for a complete monitoring solution.

This guide specifically focuses on host-level and Ocient® software metrics. Monitoring additional components (e.g., Apache® Kafka®) is outside of the scope of this document.

These instructions were created using these versions of each component.

| Component | Version |
|---|---|
| InfluxDB | 1.8 (OSS) |
| Telegraf | 1.16.1 |
| Kapacitor | 1.5.6 (OSS) |
| Grafana | 7.4.3 |

# Prerequisites

This guide assumes that:

1. SSH access and root-level privileges are available to each server running Ocient Software.
2. InfluxDB, Kapacitor, and Grafana are available to be installed in a virtual machine or container. It is important to note that each of these systems should be run independently. For example, do not run InfluxDB, Kapacitor, and Grafana on the same virtual machine.
3. All Ocient software is currently deployed and running as expected.
4. Logging configuration is set up as specified in **Log Configuration**.
5. The following ports must be open for InfluxDB, Kapacitor, Telegraf, and Grafana. InfluxDB is the most critical as each component communicates with it. Always refer to the latest documentation for each product as the definitive reference.

| Component | Default Ports | Components Requiring Access |
|---|---|---|
| InfluxDB | 8086 8088 (optional, used for backup utilities) | Telegraf, Kapacitor, Grafana |
| Telegraf | None | None |
| Kapacitor | 9092 | None |
| Grafana | 3000 | None |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

# Step 1: Deploy InfluxDB

InfluxDB is a timeseries database that provides persistence for the host-level and Ocient software metrics.

1. Refer to current instructions from InfluxDB on how to install the service:
**https://docs.influxdata.com/influxdb/v2.0/install/**
**https://docs.influxdata.com/influxdb/v2.0/get-started/**

2. Document the IP address of the machine where InfluxDB is installed.

3. Ensure that InfluxDB is running properly.

Shell

```
/> sudo systemctl status influxdb
influxdb.service - InfluxDB is an open-source, distributed, time series database
Loaded: loaded (/lib/systemd/system/influxdb.service; enabled; vendor preset: enabl
Active: active (running) since Tue 2021-09-14 17:17:20 UTC; 3 weeks 2 days ago
Docs:
Main PID: 32687 (influxd)
Tasks: 18 (limit: 4915)
CGroup: /system.slice/influxdb.service
└─32687 /usr/bin/influxd -config /etc/influxdb/influxdb.conf/
```

4. Set the InfluxDB service to start on boot.

Shell

```
/> sudo systemctl enable influxdb
```

5: It is highly recommended that critical components of monitoring infrastructure, including InfluxDB, are also monitored. Monitoring the monitoring stack is outside of the scope of this document. Refer to available resources on potential solutions to monitor InfluxDB.

# Step 2: Deploy and Configure Telegraf

Telegraf is used for metrics collection. It runs on each of the Admin, Loader, Foundation, SQL Nodes. The following instructions highlight the common configuration elements, followed by the elements that are specific to different node types.

## All Nodes

1. Install **Telegraf** on each of the Admin, Loader, Foundation, and SQL Nodes. Refer to the Telegraf installation instructions available from InfluxDB. At this point, do not start the Telegraf service or generate the default configuration.

2. For **all nodes**, create the Telegraf configuration file (typically located at `/etc/telegraf/telegraf.conf`). Open the file in an editor.

- Copy and paste the following contents into the file.
- Replace the designated placeholders (denoted with a $) with the specific values for the specified environment:
  - `CLUSTER_NAME =` — Customer-selected name of a provided cluster for monitoring identification
  - `ROLE =` — One of `admin`, `loader`, `lts`, `sql`, or `stream_proc`, depending on the node type
  - `INFLUX_URL =` — URL of the InfluxDB instance (e.g., `http://10.6.0.4:8086`)

© 2026 Ocient, Inc

Text

```
; /etc/telegraf/telegraf.conf
[global_tags]
   cluster = "$CLUSTER_NAME"
   cluster_role = "$ROLE" # one of admin, loader (aka indexer), lts (aka foundation

[agent]
  interval = "15s" # time
  metric_batch_size = 1000 # size
  metric_buffer_limit = 100000 # size
  collection_jitter = "3s" # time
  flush_interval = "7s" # time
  flush_jitter = "3s" # time
  round_interval = false

[outputs]

[[outputs.influxdb]]
  urls = [ "$INFLUX_URL" ]
  database = "telegraf"
  precision = "1s"
  timeout = "10s"
```

Save the file.

3. For **all nodes**, create a new file under the telegraf.d directory (typically `/etc/telegraf/telegraf.d`) named `host.conf`.

- Copy and paste the following contents into the file.
- Replace the designated placeholders (denoted with an `$`) with the specific values for the specified environment:
  - `BOOT_DISK` — Device name of the boot disk (e.g., `sda`). You can determine the boot disk by running an `lsblk` command.
  - `NET_INT_BONDO_WILDCARD` — The wildcard for matching the underlying network interfaces within `bond0` (e.g., `eno*`). If it is unclear, refer to `/proc/net/bonding/bond0` and reference the interfaces noted in the **Telegraf documentation**.

- `NET_INT_BOND1_WILDCARD` — The wildcard for matching the underlying network interfaces within `bond1` (e.g., `enp*`). If it is unclear, refer to `/proc/net/bonding/bond1` and reference the interfaces noted in the **Telegraf documentation**.

Text

```
; /etc/telegraf/telegraf.d/host.conf
[[inputs.cpu]]
    percpu = true
    totalcpu = true
    fielddrop = [ "time_*" ]
[[inputs.disk]]
    ignore_fs = ["tmpfs", "devtmpfs", "vfat"]
[[inputs.diskio]]
    skip_serial_number = true
    devices = ["$BOOT_DISK"]
    [inputs.diskio.tags]
        disk_type="os"

[[inputs.mem]]

[[inputs.net]]
    interfaces = ["$NET_INT_BOND0_WILDCARD", "$NET_INT_BOND1_WILDCARD"]

[[inputs.net]]
    interfaces = ["bond0"]
    [inputs.net.tags]
        primary_interface_10Gb = "true"
    [inputs.net.tagdrop]
        interface = [ "all" ]

[[inputs.net]]
    interfaces = ["bond1"]
    [inputs.net.tags]
        primary_interface_100Gb = "true"
    [inputs.net.tagdrop]
        interface = [ "all" ]

[[inputs.system]]
[[inputs.swap]]

[[inputs.linux_sysctl_fs]]
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Save the file.

4. For **all nodes**, create a new file under the telegraf scripts directory (typically under `/etc/telegraf/scripts`) named `uio_pci_generic.sh`.

- Copy and paste the following contents into the file.

Shell

```
; /etc/telegraf/scripts/uio_pci_generic.sh
; A script used to enumerate the PCI devices on the system.
;
; !/bin/bash

DEVICES=$(find /sys/bus/pci/drivers/uio_pci_generic/0000:* | awk -F'/' '{ print $NF

for d in $DEVICES; do
  echo pci_devices,device=\"$d\" present=1
done
```

## Foundation and SQL Nodes

Create a new file under the `telegraf.d` directory (typically `/etc/telegraf/telegraf.d`) named `rolehostd.conf`.

- Copy and paste the following contents into the file.
- Replace the designated placeholders (denoted with an $) with the specific values for the specified environment:
  - `NODE_BONDO_IP_ADDRESS =` IP address associated with bond0

Text

```
[inputs.http]]
  urls = [
    "http://$NODE_BONDO_IP_ADDRESS:9090/v1/status"
  ]
  method = "GET"
  timeout = "5s"
  name_override = "rolehostd_status"
  data_format = "value"
  data_type = "string"

[[inputs.http_response]]
  urls = [
    "http://$NODE_BONDO_IP_ADDRESS:9090/v1/status"
  ]
  method = "GET"
  response_timeout = "5s"
  name_override = "rolehostd_status_response"
  response_string_match = "Active"

[[inputs.http]]
  urls = [
    "http://$NODE_BONDO_IP_ADDRESS:9090/v1/stats"
  ]
  method = "GET"
  timeout = "5s"
  name_override = "rolehostd"
  json_time_key = "time"
  json_time_format = "unix_us"
  json_string_fields = ["units"]
  data_format = "json"
  tagexclude = ["url", "node"]
  tag_keys = [
    "name",
    "socket",
    "device"
  ]

[[inputs.http]]
  urls = [
    "http://$NODE_BONDO_IP_ADDRESS:9090/v1/version"
      ]
  method = "GET"
```

```
  timeout = "5s"
  name_override = "rolehostd_version"
  json_query = "{build_type,version}"
  json_string_fields = ["build_type","version"]
  data_format = "json"

[[inputs.http]]
  urls = [
    "http://$NODE_BONDO_IP_ADDRESS:9090/v1/operatorsummary"
  ]
  method = "GET"
  timeout = "5s"
  name_override = "rolehostd_operatorsummary"
  data_format = "json"

[[inputs.exec]]
  commands = ['sh /etc/telegraf/scripts/uio_pci_generic.sh']
  data_format = "influx"

[[inputs.tail]]
    name_override = "tail_query_json"
    files = ["/var/opt/ocient/log/query.json","/var/opt/ocient/query.json"]
    data_format = "json"
    json_query = "{src,msg.user,msg.database,msg.service_class,msg.client_version,m
    tag_keys = ["src","user","database","service_class","code","major_driver_versio
    json_string_fields = ["client_version","client_ip","timestamp_start","timestamp

[[processors.converter]]
    namepass=["tail_query_json"]
    [processors.converter.fields]
        integer = ["timestamp_start","timestamp_execstart","timestamp_complete"]
```

You can also use **Filebeat** to forward the `query.json` file to a monitoring platform of your choice.

## Admin and Loader Nodes

Create a new file under the `telegraf.d` directory (typically `/etc/telegraf/telegraf.d`) named `rolehostd.conf`.

- Copy and paste the following contents into the file.

- Replace the designated placeholders (denoted with an $) with the specific values for the specified environment:
  - `NODE_BONDO_IP_ADDRESS =` IP address associated with bond0

Text

```
; /etc/telegraf/telegraf.d/rolehostd.conf
[[inputs.http]]
  urls = [
    "http://$NODE_BONDO_IP_ADDRESS:9090/v1/status"
  ]
  method = "GET"
  timeout = "5s"
  name_override = "rolehostd_status"
  data_format = "value"
  data_type = "string"

[[inputs.http_response]]
  urls = [
    "http://$NODE_BONDO_IP_ADDRESS:9090/v1/status"
  ]
  method = "GET"
  response_timeout = "5s"
  name_override = "rolehostd_status_response"
  response_string_match = "Active"

[[inputs.http]]
  urls = [
    "http://$NODE_BONDO_IP_ADDRESS:9090/v1/stats"
  ]
  method = "GET"
  timeout = "5s"
  name_override = "rolehostd"
  json_time_key = "time"
  json_time_format = "unix_us"
  json_string_fields = ["units"]
  data_format = "json"
  tagexclude = ["url", "node"]
  tag_keys = [
    "name",
    "socket",
    "device"
  ]

[[inputs.http]]
  urls = [
    "http://$NODE_BONDO_IP_ADDRESS:9090/v1/version"
  ]
```

```
  method = "GET"
  timeout = "5s"
  name_override = "rolehostd_version"
  json_query = "{build_type,version}"
  json_string_fields = ["build_type","version"]
  data_format = "json"

[[inputs.exec]]  commands = ['sh /etc/telegraf/scripts/uio_pci_generic.sh']
  data_format = "influx"

[[inputs.tail]]
    name_override = "tail_query_json"
    files = ["/var/opt/ocient/log/query.json","/var/opt/ocient/query.json"]
    data_format = "json"
    json_query = "{src,msg.user,msg.database,msg.service_class,msg.client_version,m
    tag_keys = ["src","user","database","service_class","code","major_driver_versio
    json_string_fields = ["client_version","client_ip","timestamp_start","timestamp

[[processors.converter]]
    namepass=["tail_query_json"]
    [processors.converter.fields]
        integer = ["timestamp_start","timestamp_execstart","timestamp_complete"]
```

## Loader Nodes

Loader Nodes also run the Loading and Transformation service and require additional Telegraf configuration to capture those metrics.

- Create a new file under the `telegraf.d` directory (typically `/etc/telegraf/telegraf.d`) named `lat.conf`.
- Copy and paste the following contents into the file.

Text

```
; /etc/telegraf/telegraf.d/lat.conf
[[inputs.jolokia2_agent]]
  urls = ["http://localhost:8080/v2/metrics"]

  [[inputs.jolokia2_agent.metric]]
    name  = "pipeline"
    mbean = "lat:type=pipeline"

  [[inputs.jolokia2_agent.metric]]
    name  = "partitions"
    mbean = "lat:type=partitions"

[[inputs.procstat]]
  systemd_unit = "lat.service"
```

## Start Telegraf

When the configuration is properly entered on all nodes, Telegraf must be started.

1. On **each node**, start the Telegraf service.

Shell

```
/> sudo systemctl start telegraf
```

2. Ensure the service came up properly by checking the status.

Shell

```
/> sudo systemctl status telegraf
telegraf.service - The plugin-driven server agent for reporting metrics into Influx
Loaded: loaded (/usr/lib/systemd/system/telegraf.service; enabled; vendor preset: d
Active: active (running) since Thu 2021-08-05 22:04:06 UTC; 2 months 3 days ago
Docs: https://github.com/influxdata/telegraf
Main PID: 2651775 (telegraf)
Tasks: 103 (limit: 1589476)
Memory: 221.2M
CGroup: /system.slice/telegraf.service
└─2651775 /usr/bin/telegraf -config /etc/telegraf/telegraf.conf -config-directory /
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

3. Set the Telegraf service to start on boot.

```shell
/> sudo systemctl enable telegraf
```

## Step 3: Deploy and Configure Kapacitor

Kapacitor is used to process time series data, detect anomalies, and trigger alerts. As the preferred alerting mechanisms for every customer will vary, refer to the Kapacitor documentation on **how to send alerts through specific tools**.

1. Install Kapacitor using the instructions from InfluxDB.
**https://docs.influxdata.com/kapacitor/v1.6/introduction/installation/**

2. Create the Kapacitor configuration file (typically located at `/etc/kapacitor/kapacitor.conf`). Open the file in an editor.

- Copy and paste the following contents into the file.
- Replace the designated placeholders (denoted with an $) with the specific values for the specified environment:
  - `KAPACITOR_HOST_OR_IP =` — Hostname or IP address associated with the Kapacitor instance
  - `INFLUX_URL =` — URL of the InfluxDB instance (e.g., `http://10.6.0.4:8086`)

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Text

```
; /etc/kapacitor/kapacitor.conf
hostname = "$KAPACITOR_HOST_OR_IP"
data_dir = "/var/lib/kapacitor"
skip-config-overrides = false

[logging]
    # Destination for logs
    # Can be a path to a file or 'STDOUT', 'STDERR'.
    file = "/var/log/kapacitor/kapacitor.log"
    level = "ERROR"

[load]
  enabled = true
  dir = "/etc/kapacitor/load"

[replay]
  # Where to store replay files, aka recordings.
  dir = "/var/lib/kapacitor/replay"

[storage]
  boltdb = "/var/lib/kapacitor/kapacitor.db"

[[influxdb]]
  enabled = true
  default = true
  name = "influx"
  urls = ["$INFLUX_URL"]
  username = "admin"
  password = ""
  timeout = "10s"

  startup-timeout = "60s"

  # Subscription mode is either "cluster" or "server"
  subscription-mode = "server"

  # Which protocol to use for subscriptions
  # one of 'udp', 'http', or 'https'.
    subscription-protocol = "http"

  # Subscriptions resync time interval
  # Useful if you want to subscribe to new created databases
```

```
  # without restart Kapacitord
  subscriptions-sync-interval = "1m0s"

; INSERT ALERT DESTINATION CONFIGS HERE

[stats]
  enabled = true
  stats-interval = "10s"
  database = "_kapacitor"
  retention-policy= "autogen"
```

## Add Kapacitor Alerts and Templates

Ocient provides sample Kapacitor alerts and templates upon request. Contact Ocient Support for details.

Within the bundle, relevant contents are located within the `kapacitor` directory.

1. Copy the files located under `kapacitor/load/tasks` to the Kapacitor system in `/etc/kapacitor/load/tasks`.
2. Copy the files located under `kapacitor/load/templates` to the Kapacitor system in `/etc/kapacitor/load/templates`.

## Start Kapacitor

When the configuration is complete, Kapacitor must be started.

1. On **each node**, start the Kapacitor service.

Shell

```
/> sudo systemctl start kapacitor
```

2. Ensure the service came up properly by checking the status.

© 2026 Ocient, Inc

Shell

```
/> sudo systemctl status kapacitor
kapacitor.service - Time series data processing engine.
   Loaded: loaded (/lib/systemd/system/kapacitor.service; enabled; vendor preset: e
   Active: active (running) since Fri 2021-09-03 18:30:37 UTC; 1 months 9 days ago
     Docs: https://github.com/influxdb/kapacitor
 Main PID: 16177 (kapacitord)
    Tasks: 16 (limit: 4915)
   CGroup: /system.slice/kapacitor.service
           └─16177 /usr/bin/kapacitord -config /etc/kapacitor/kapacitor.conf

Sep 03 18:30:37 kapacitor systemd[1]: Started Time series data processing engine..

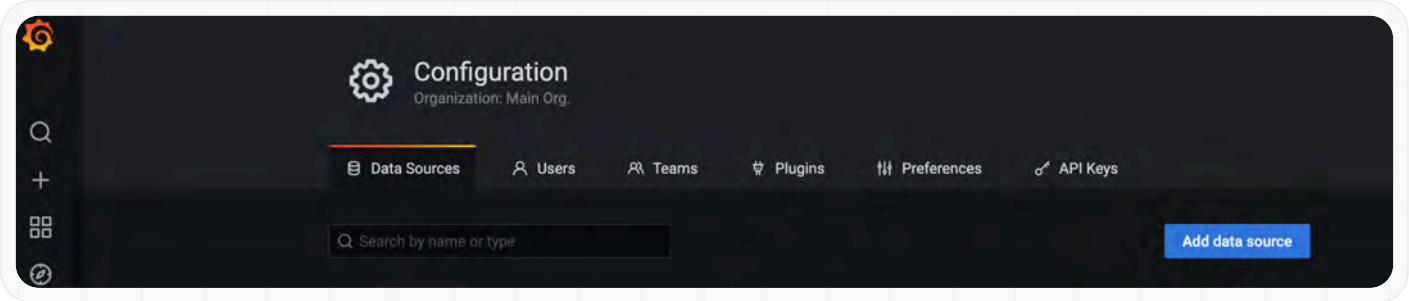
Sep 03 18:30:37 kapacitor kapacitord[16177]: 2021/09/03 18:30:37 Using configuratic
```

3. Set the Kapacitor service to start on boot.

Shell

```
/> sudo systemctl enable kapacitor
```

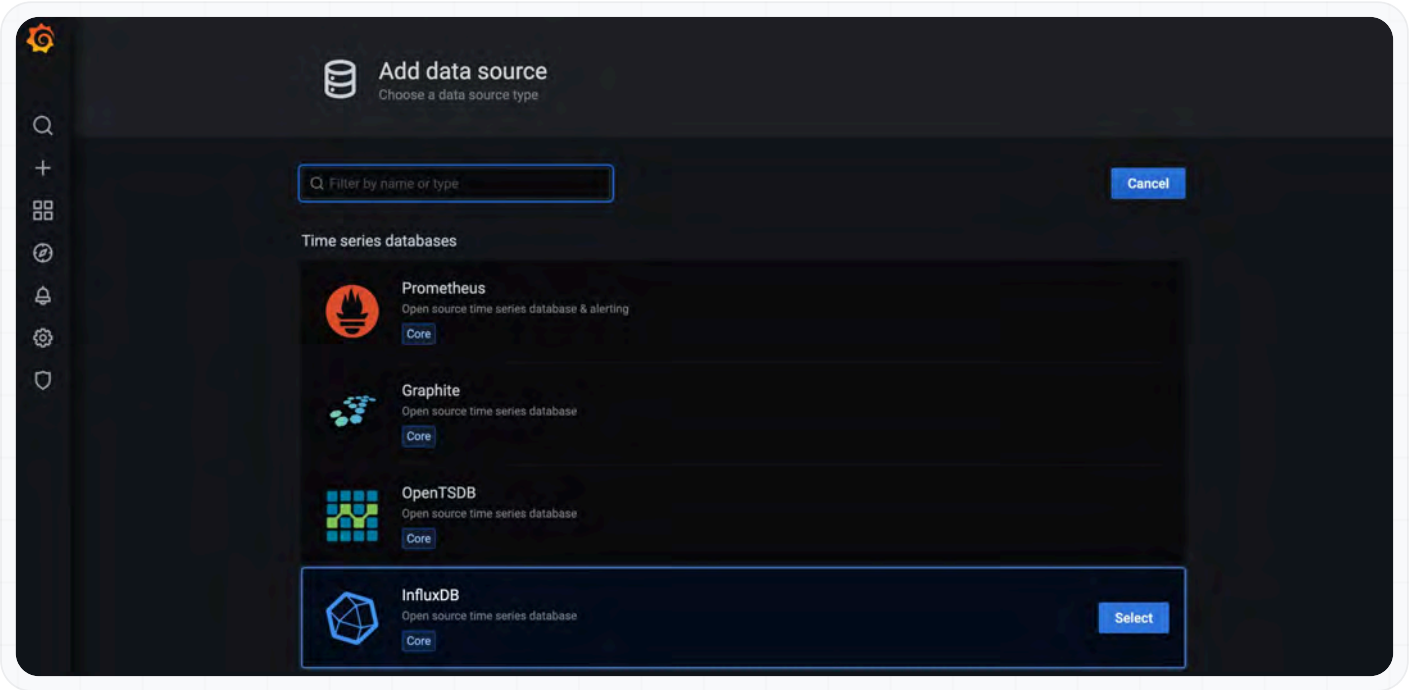
## Step 4: Deploy and Configure Grafana



Grafana provides the dashboard and visualization capability for metrics. This tool is used as opposed to Chronograf™, which is traditionally used to complete the TICK (Telegraf, InfluxDB, Chronograf, and Kapacitor) stack. Grafana is favored over Chronograf due to its versatility beyond the InfluxDB ecosystem, as well as higher frequency of contributions and updates from the broader community.

Install Grafana. Follow the Grafana instructions to ensure that configuration options for items such as users, permissions, and logging all correspond to the environment.
**https://grafana.com/docs/grafana/latest/installation/**

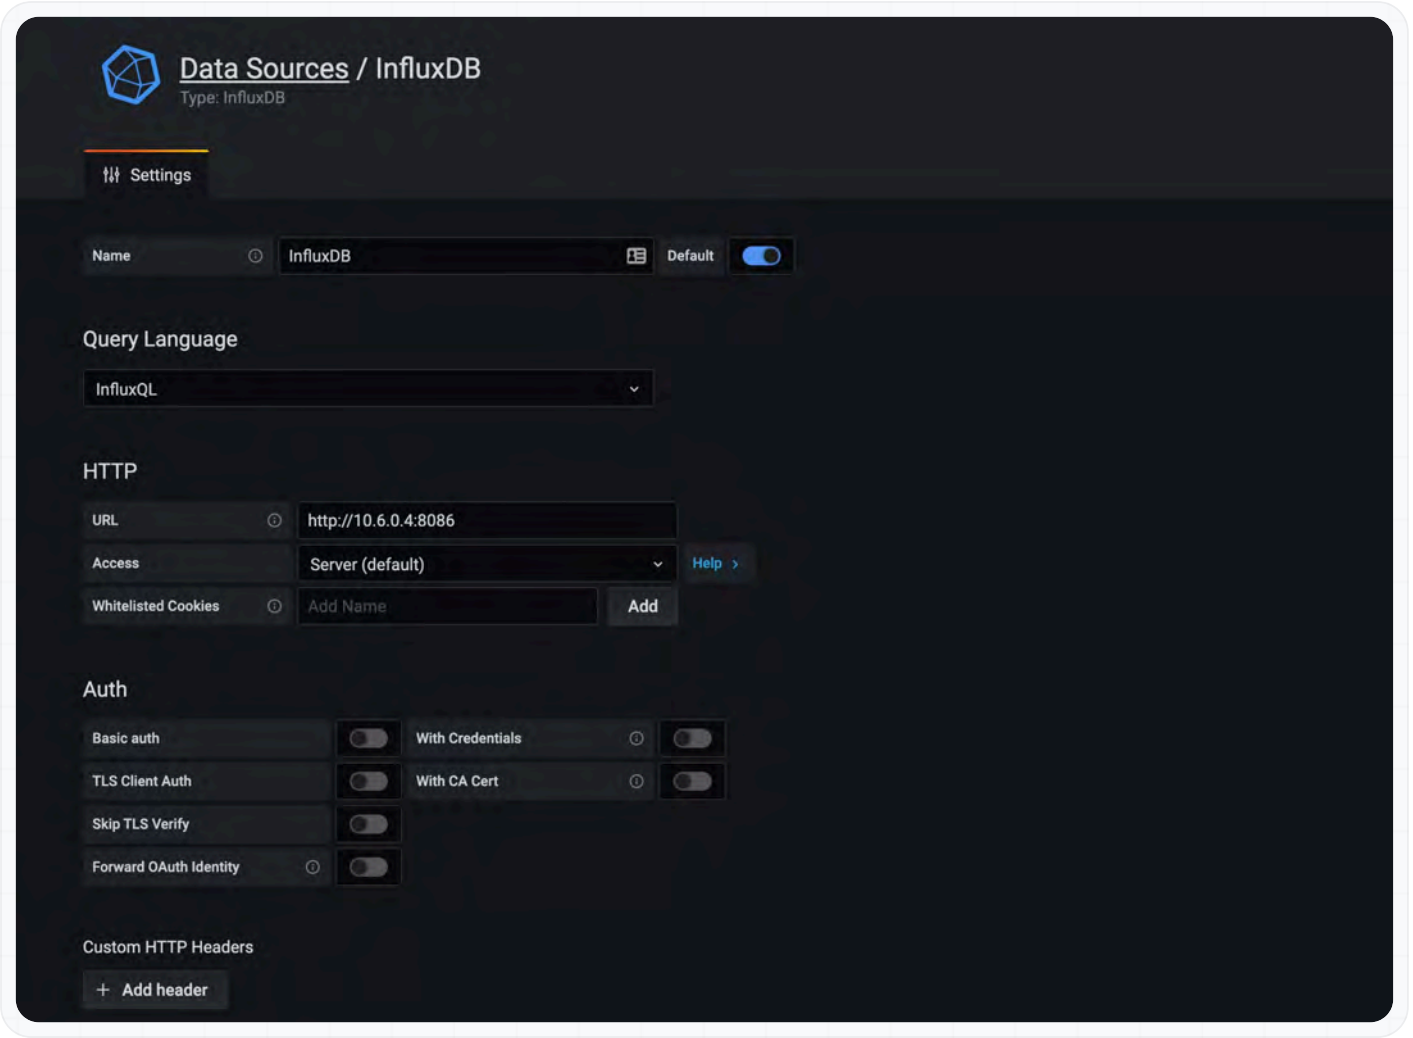
## Add InfluxDB as a Data Source



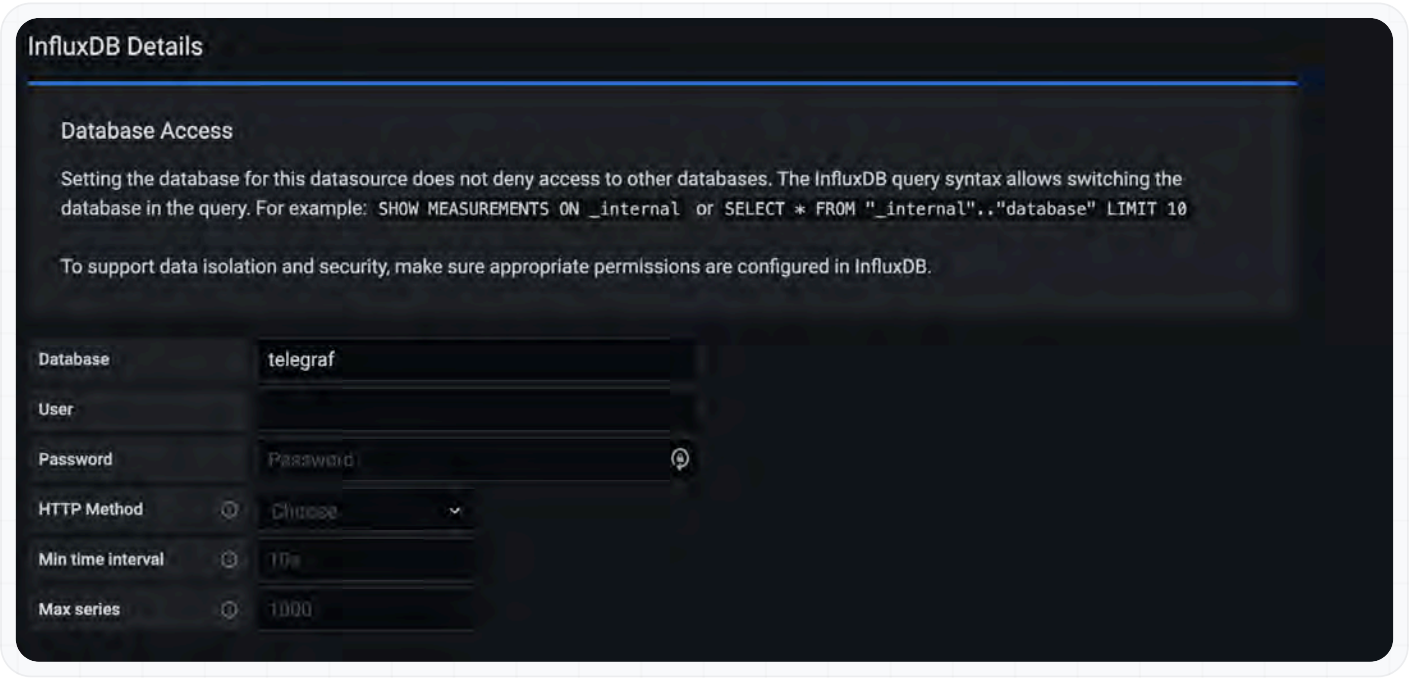
1. Open Grafana in a web browser.

2. In the Grafana UI, select the Settings tab on the left side of the screen. Select **Configuration->Data Sources**.

3. Select **Add data source**.



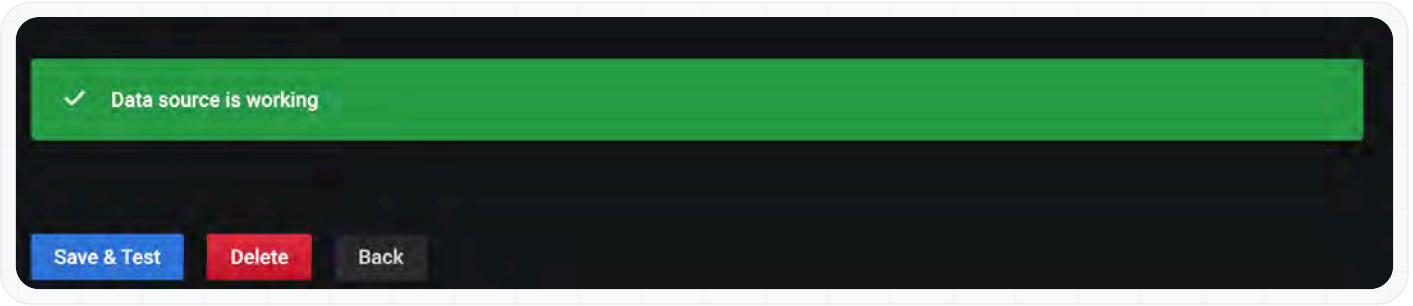
4. Under the data source list, select InfluxDB. Select the **Select** button.



5. Enter all of the pertinent configuration details associated with the InfluxDB instance:

- Ensure the data source is marked as the Default.
- Under the HTTP section, the URL should be the same as the INFLUX_URL used in previous sections.
- The query language should be set to the default (InfluxQL).

© 2026 Ocient, Inc
Ocient Proprietary and Confidential



6. Under the InfluxDB Details section, specify `telegraf` as the database name.

7. When the configuration appears to be correct, select **Save and Test**.

8. A green banner should appear that indicates the connection to the data source is working properly. If this message does not display, consult the Grafana documentation or contact Ocient Support.

### Import Dashboards

Ocient provides sample Grafana dashboards upon request. Contact Ocient Support for details.

Within the bundle, relevant contents are located within the `grafana` directory.

> Grafana only allows one file at a time.

1. Open Grafana in a web browser.
2. In the Grafana UI, select the *+ ("Create")* tab on the left side of the screen. Select the **Import** option.
3. On the Import page, select the **Upload JSON File** button.
4. Select the file representing the dashboard you wish to import.
5. On the dashboard summary page, verify the settings are correct. Select **Import** to complete the process.
6. Repeat steps 3-6 for each dashboard that needs to be added.

# Monitor Segment Group Transfers

Monitor segment group transfers in Ocient during expansions, rebuilds, or rebalances using SQL queries and system catalog tables to track transfer progress.

You can perform segment group transfers in the Ocient® System. Use the data in the `sys.segment_group_transfers` system catalog table to monitor this activity.

## Segments, Segment Groups, and Segment Group Transfers

A segment is the primary storage unit. Individual segments combine together to form segment groups. For details, see **Core Elements of an Ocient System**.

In a system that has multiple storage clusters, the Ocient System might experience a data imbalance between clusters. In this case, you might need to transfer segment group ownership between clusters. Transferring segment groups enables you to transfer the physically stored segments between clusters. During or after the segment group transfer, you can monitor the activity using the `sys.segment_group_transfers` system catalog table.

## Segment Group Transfers System Catalog Table

The database contains the system catalog table named `sys.segment_group_transfers` with these columns:

- `id` — A Universally Unique IDentifier (UUID) that represents the transfer identifier.
- `src_cluster_id` — The UUID of the source cluster.
- `dst_cluster_id` — The UUID of the destination cluster.
- `status` — The current status of the transfer.
  - `ACTIVE` — The transfer is ongoing.
  - `COMPLETE` — The transfer is complete and the segment groups are owned by the destination cluster.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

    - `FAILED` — The transfer is not complete and the segment groups are owned by the source cluster. A transfer can be in this state due to an error that prevented the system from transferring segment groups or due to a canceled transfer.
- `segment_group_ids` — An array of uint64 segment group identifiers.
- `src_committed_osn` — The ownership sequence number (OSN) where the source cluster no longer returns the segment groups in the transfer for queries.
- `dst_committed_osn` — The OSN where the destination cluster added the segment groups. The destination cluster does not return the segment groups for queries unless the query uses at least the `src_committed_osn` value for the OSN of the source cluster.

The database removes segment group transfers from the system upon completion.

# Inspect the Current Configuration

Inspect the current configuration of an Ocient System using SQL queries, the REST API, and system catalog tables to verify settings before changes.

Ocient® includes a variety of configuration settings that control how the system behaves. The vast majority of these do not change in a typical deployment. However, there is a small set more commonly changed to adjust for different workloads, hardware, and operating requirements.

Configuration is primarily done through DDL or DCL and can be inspected using the **System Catalog Reference**.

You can contact Ocient Support to change configuration settings that apply across the entire system or to a subset of nodes. Each Ocient node reads configuration settings during startup. Therefore, configuration changes require restarts for the new values to take effect. For details, contact Ocient Support.

## Inspecting System Configuration

Administrators typically need to know the effective configuration of the system and what has been overridden.

- Configuration Overrides — a list of the overrides applied by administrators
- Effective Configuration — the complete list of all configuration parameters and their current values on each node

### Viewing Configuration Overrides

A system catalog table is provided that lists all DDL Configuration Overrides that are applied to the Ocient System. This table includes the configuration target type as well as the scope to which it is applied.

In the event that the scope is not `SYSTEM` (See Advanced Configuration for `CLUSTER` and `NODE` scopes), the `scope_id` indicates the `cluster_id` or `node_id` to which the configuration override applies.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### Example

The following query retrieves all config overrides applied on the system and provides a friendly node name or cluster name where an override is limited in scope:

SQL

```
SELECT
  cfg.scope_type,
  n.name AS node_name,
  c.name AS cluster_name,
  cfg.key,
  cfg.value
FROM
  sys.config cfg
  LEFT JOIN sys.nodes n
  ON n.id = cfg.scope_id and cfg.scope_type = 'NODE'
  LEFT JOIN sys.clusters c
  ON c.id = cfg.scope_id and cfg.scope_type = 'CLUSTER';
```

Output

SQL

```
scope_type                                        node_name
--------------------------------------------------------------------------------
NODE                                              sales-lts8
SYSTEM                                            NULL
CLUSTER                                           NULL
NODE                                              sales-lts8
SYSTEM                                            NULL
...
```

## Viewing Effective Configuration Using System Table

A system catalog table is provided that lists the effective configuration of each node.

### Example

The following query retrieves the effective overrides for the SQL role on the specified node:

```sql
SELECT
  n.name,
  nc.key,
  nc.value
FROM
  sys.node_config nc
  JOIN sys.nodes n
  ON nc.node_id = n.id
  WHERE n.name = 'sql0'
  AND key LIKE 'sql%';
```

Output

Text

```
name                                                key
-------------------------------------------------------------------------------
sql0                                                sql.blobstoreParameters.regionAlloca
sql0                                                sql.blobstoreParameters.pageUtilizat
sql0                                                sql.blobstoreParameters.pageUtilizat
sql0                                                sql.blobstoreParameters.maxFileSize
sql0                                                sql.blobstoreParameters.minFileSize
sql0                                                sql.blobstoreParameters.blobPageSize
sql0                                                sql.blobstoreParameters.stripeWidth
sql0                                                sql.blobstoreParameters.coreMask

sql0                                                sql.pdfReservedMem
sql0                                                sql.numLevels
sql0                                                sql.maxShutdownWaitTime
sql0                                                sql.shortQueryMillis
sql0                                                sql.timeLimit
sql0                                                sql.forceNetworkedVirtualTables
sql0                                                sql.cacheLimit
sql0                                                sql.optimizer
sql0                                                sql.generator
sql0                                                sql.validator
sql0                                                sql.concurrencyTarget
```

## Viewing Effective Configuration Using REST Endpoints

Administrators can also view the effective system configuration using the config endpoint, a REST interface available on each node. This endpoint shows every configuration parameter for the node and its current value. It reflects the active values and might not reflect configuration overrides applied since the last node restart.

The config endpoint is found on each node at `http://<node_hostname_or_ip_address>:9090/v1/config` and it returns a JSON representation of the active system configuration of the targeted node.

### Example

CURL

```
curl http://10.0.1.7:9090/v1/config
```

Output

JSON

```
{
    "siloType": "xg::runtime::physicalSiloSet_t",
    "tlbfsInfo.enabled": "true",
    "gdsClientParameters_t.batchTimer": "150000000n",
    "gdsClientParameters_t.maxBatchCount": "4096"
    ...
    "operatorvm.vmSiloMask": "0x3",
    "operatorvm.vmParameters.levels": "0x4",
    "operatorvm.vmParameters.statsCacheSize": "4GiB",
    "operatorvm.vmProtocolParameters.routerPollRate": "250000000n",
    "operatorvm.vmProtocolParameters.bufferedDatablockTimeout": "120000000000n"
    ...
    "lts.ioOpParameters.bufferPool.backingSlabSize": "2MiB",
    "lts.ioOpParameters.bufferPool.bufferPools[0].pool.size": "4KiB",
    "lts.ioOpParameters.bufferPool.bufferPools[0].pool.count": "98304",
    "lts.ioOpParameters.lbaCacheSize": "64",
    "lts.targetFillRatio": "1",
    "lts.pdfReservedMem": "4GiB"
    ...
}
```

# Node Configuration with the Administrator Role

Configure individual nodes in an Ocient System using the Administrator role, including bootstrapping parameters, storage settings, and per-node overrides.

Nodes with the `admin` role have the additional responsibility to store important metadata for compression and system configuration. In most cases, an OcientAIQ™ Unified Data Platform system should have the majority of SQL Nodes assigned to the `admin` role.

## Administrator Node Redundancy

To ensure high availability and consistency, an Ocient® System must always have a minimum number of operational nodes with `admin` privileges.

Redundancy for the system configuration and dictionary compression operates using a majority present model. In a system with `N` nodes configured with the `admin` role, at least `N / 2 + 1` must be present and active for the system to function correctly, where `N` is the total number of nodes, and `N / 2` denotes the division floor (i.e., rounded down to the nearest integer).

This table shows the number of nodes with `admin` privileges that can fail before the system experiences problems. Both columns comprise only nodes assigned the `admin` role, not the entire system node count.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Number of Nodes | Node Failures Tolerated |
|---|---|
| 1 | 0 |
| 2 | 0 |
| 3 | 1 |
| 4 | 1 |
| 5 | 2 |
| 6 | 2 |
| 7 | 3 |

⚠ Various core system functions risk failure if the number of nodes running the `admin` role falls below the tolerance threshold. Operations that could fail include:

- System startup
- System configuration
- Query execution
- Data loading

ⓘ The majority present model for nodes with the `admin` role is different than parity encoding used for Foundation Nodes.

For details on parity width for Foundation Nodes, see **Configure Storage Spaces**.

# Administrator Node Metadata

This table describes additional metadata files stored by nodes running the `admin` role. If you remove the `admin` role from a node, the system removes these files.

| File path | Description |
|---|---|
| `/var/opt/ocient/metadataStorage.raft` | Definitions for users, network configuration, and database objects. |
| `/var/opt/ocient/globalDataStorage.raft` | Compression dictionaries for the `COMPRESSION GDC` columns. |

## Configure Nodes with the Administrator Role

To configure a node to run the `admin` role, execute this SQL statement.

```SQL
ALTER NODE nodename ADD ROLE admin;
```

It is generally a good practice to have all SQL Nodes in your system assigned to run the `admin` role. You can configure additional nodes with the `admin` role to adjust the level of redundancy to your chosen level.

# Manage the Network Configuration of an Ocient System

Manage network configuration for an Ocient System, including hostnames, IP addresses, ports, NIC bonding, and inter-node communication for production.

Connectivity pools configure the external networking interfaces that clients use to connect to an Ocient® System. They define the addresses and ports that SQL Nodes listen on and control how clients such as JDBC, pyocient, and the HTTP Query API (OpenAPI) interact with the system. Connectivity pools do not affect the internal network configuration that Ocient Nodes use to communicate with each other.

## Connectivity Pool Behavior

A connectivity pool groups one or more SQL Nodes together and provides clients with the network information needed to connect. A connectivity pool serves three purposes:

- Defines listen endpoints — Each participant node in the pool specifies the address and port where it accepts connections for both the SQL wire protocol and the HTTP Query API.
- Advertises connection information — Each participant can advertise a different address and port than it listens on, which is essential when clients connect through Network Address Translation (NAT) or load balancers.
- Enables automatic client redirection — The system can automatically redirect JDBC and pyocient clients connecting to any node in a pool to the least busy node within the same pool. This redirection provides client-side load balancing without external infrastructure.

> The HTTP Query API (OpenAPI) does not support automatic redirection because cross-origin request restrictions make it impractical. Use DNS round-robin or an external load balancer for OpenAPI load distribution.

All SQL Nodes in the system must belong to at least one connectivity pool. Each node can belong to multiple pools. For the DDL statements for managing connectivity pools, see **CONNECTIVITY POOL**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Connectivity pools do not support dynamic IP addresses. If the IP address of your SQL Node changes, you must manually update it by using an **ALTER CONNECTIVITY_POOL ALTER PARTICIPANT** SQL statement.

## Default Behavior

The Ocient System creates a single shared connectivity pool named `system` during bootstrap. All SQL Nodes automatically join this pool as participants. When you add a new SQL Node to the cluster, the system automatically adds it to the `system` pool.

This default behavior enables automatic client redirection between all SQL Nodes, which is the chosen behavior for most deployments. You do not need any additional configuration.

## Pool Selection Behavior

When a client connects to a SQL Node, the system determines which connectivity pool to use through the following process:

1. The system identifies all pools that have a participant listening on the connected address and port.
2. The system filters pools by `SOURCE_ADDRESS`, matching the source IP address of the client against the CIDR range of each pool.
3. If a pool specifies the `SOURCE_PORT` value, the connection port must also match.
4. Among all matching pools, the system selects the pool with the highest `PRIORITY` value.
5. The system associates the client with that pool. For JDBC and pyocient connections, redirection uses the `ADVERTISED_ADDRESS` and `ADVERTISED_PORT` values of nodes within the selected pool.

This selection process allows you to direct clients from different networks to different pools. For example, internal clients can match a higher-priority pool that advertises internal hostnames, while external clients match a lower-priority pool that advertises external hostnames.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Initial Configuration

For most deployments, the default `system` pool provides the correct behavior without additional configuration.

To customize your initial connectivity pool configuration, use the **CREATE CONNECTIVITY_POOL** statement or specify the configuration in the `bootstrap.conf` file. For details about the `bootstrap.conf` file, see **Node Bootstrapping Reference**.

## Expand the Network of an Ocient System

The system adds new SQL Nodes to the `system` pool. No manual steps are required.

If you use custom connectivity pools instead of the default `system` pool, you can add new SQL Nodes to an existing pool using the **ALTER CONNECTIVITY_POOL ADD PARTICIPANTS** statement.

## Change the Network Configuration of an Ocient System

You can configure IP addresses that the Ocient System uses to connect to the external client or to other nodes in the system. Configure IP addresses for external client connections using the **ALTER CONNECTIVITY_POOL** SQL statement. Configure IP addresses for connections with other nodes in the system using the **ALTER NODE SET ADDRESS** SQL statement.

The system automatically adds new SQL Nodes to the `system` pool. If you use custom connectivity pools, you might need to configure the pools using the **CONNECTIVITY_POOL** SQL statements after adding a new SQL Node or adding a SQL role using the **ALTER NODE ADD ROLE** SQL statement.

## Common Deployment Scenarios

These scenarios illustrate common connectivity pool configurations for different network topologies and workload requirements. Each scenario includes the SQL statements needed to create and configure the pools.

## Single Pool With All Nodes

This deployment is the simplest and most common. All SQL Nodes share one connectivity pool, and you can redirect clients connecting to any node to the least busy node.

This behavior is the default with the `system` pool. You do not need any additional configuration. You can verify the configuration by querying the system catalog.

SQL

```
SELECT name, source_address, priority
FROM sys.connectivity_pools;
```

SQL

```
SELECT pool_name, node_name,
    listen_address, listen_port,
    advertised_address, advertised_port
FROM sys.connectivity_pool_participants;
```

## NAT: Internal and External Networks

When clients access SQL Nodes through a NAT gateway, the internal and external addresses differ. Create two connectivity pools: one for internal clients and one for external clients.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE CONNECTIVITY_POOL internal_pool
    SOURCE_ADDRESS '10.0.0.0/8'
    PRIORITY 2
    PARTICIPANTS (
        (NODE sql0
         LISTEN_ADDRESS '0.0.0.0'
         LISTEN_PORT 4050
         ADVERTISED_ADDRESS 'sql0.internal.example.com'
         ADVERTISED_PORT 4050),
        (NODE sql1
         LISTEN_ADDRESS '0.0.0.0'
         LISTEN_PORT 4050
         ADVERTISED_ADDRESS 'sql1.internal.example.com'
         ADVERTISED_PORT 4050));

CREATE CONNECTIVITY_POOL external_pool
    SOURCE_ADDRESS '0.0.0.0/0'
    PRIORITY 1
    PARTICIPANTS (
        (NODE sql0
         LISTEN_ADDRESS '0.0.0.0'
         LISTEN_PORT 4051
         ADVERTISED_ADDRESS 'sql0.external.example.com'
         ADVERTISED_PORT 4051),
        (NODE sql1
         LISTEN_ADDRESS '0.0.0.0'
         LISTEN_PORT 4051
         ADVERTISED_ADDRESS 'sql1.external.example.com'
         ADVERTISED_PORT 4051));
```

In this example:

- Internal clients (source IP in `10.0.0.0/8`) match `internal_pool` (priority 2) and connect on port 4050. Redirection uses the internal hostnames.
- External clients (any other source IP) match `external_pool` (priority 1) and connect on port 4051. Redirection uses the external hostnames.
- Both pools listen on `0.0.0.0`, so connections arrive on any interface. The pool selection depends on the source address of the client and the priority of the pool.

## Workload Isolation

Dedicate different SQL Nodes to different workloads or tenants by placing them in separate pools. The system redirects clients connecting to a node in one pool to other nodes in the same pool.

SQL

```
CREATE CONNECTIVITY_POOL analytics_pool
    SOURCE_ADDRESS '0.0.0.0/0'
    PRIORITY 1
    PARTICIPANTS (
        (NODE sql0
         LISTEN_ADDRESS '0.0.0.0'
         LISTEN_PORT 4050
         ADVERTISED_ADDRESS 'sql0.example.com'
         ADVERTISED_PORT 4050),
        (NODE sql1
         LISTEN_ADDRESS '0.0.0.0'
         LISTEN_PORT 4050
         ADVERTISED_ADDRESS 'sql1.example.com'
         ADVERTISED_PORT 4050));

CREATE CONNECTIVITY_POOL ingest_pool
    SOURCE_ADDRESS '0.0.0.0/0'
    PRIORITY 1
    PARTICIPANTS (
        (NODE sql2
         LISTEN_ADDRESS '0.0.0.0'
         LISTEN_PORT 4050
         ADVERTISED_ADDRESS 'sql2.example.com'
         ADVERTISED_PORT 4050),
        (NODE sql3
         LISTEN_ADDRESS '0.0.0.0'
         LISTEN_PORT 4050
         ADVERTISED_ADDRESS 'sql3.example.com'
         ADVERTISED_PORT 4050));
```

In this example, analytics clients connect to `sql0` or `sql1` and the system redirects only within the `analytics_pool` pool. Ingest clients connect to `sql2` or `sql3` and the

system redirects only within the `ingest_pool` pool. The two workloads do not interfere with each other.

## Connectivity Pool Troubleshooting

If a connectivity pool misconfiguration prevents client connections, you can enable a fallback listener by adding this configuration to the `rolehostd.conf` file. This configuration causes all SQL Nodes to listen on `0.0.0.0:4050` regardless of the connectivity pool settings, allowing you to connect and correct the pool configuration.

Text

```
sql:
   defaultListen: true
```

You must restart the `rolehostd` process after you add this configuration.

Shell

```
sudo systemctl restart rolehostd
```

Alternatively, you can change the IP address of the SQL Nodes in the connectivity pool using an **ALTER CONNECTIVITY_POOL ALTER PARTICIPANT** SQL statement.

> ⚠ For existing clusters, the Ocient System configures all SQL Nodes to listen on the IP address `0.0.0.0`, allowing clients to manually create initial connectivity pools.

# Secure Connections Using TLS

Secure client and inter-node connections to an Ocient System using TLS, including certificate management, cipher configuration, and JDBC and pyocient setup.

The SQL service endpoint can make use of TLS.

The SQL service always has TLS functionality enabled and active.

The database allows connections either unencrypted, or using TLS/SSL. The certificates used to establish SSL connections are located in the directory specified by `certificateStore/path` in the `rolehostd.conf` YAML file, which is `/var/opt/ocient` by default.

The certificate files need to exist on the SQL Nodes for connecting using JDBC.

Text

```
/var/opt/ocient/server.crt
/var/opt/ocient/server.key
/var/opt/ocient/server-ca.crt
```

The server first looks for the certificate or key files named `server.crt` and `server.key` in that directory. Those files should be stored in PEM format. If those files do not exist, the database uses the same `ocient.crt` and `ocient.key` that are used for the internal cluster authentication. The `server.crt` and `server.key` files should be used to provide user-defined certificates to the database.

When these files are in place, restart the services, and they automatically make use of TLS and the specified certificate.

By default, the database allows both encrypted and unencrypted database (JDBC) connections, even if the specified `server.crt` and `server.key` files exist.

# Multiple Storage Clusters for Loading Data

Use multiple storage clusters in an Ocient System to scale loading by distributing pipeline ingestion across independent storage and compute capacity.

You can load data in the OcientAIQ™ Unified Data Platform that contains multiple storage clusters. Take these considerations into account for loading in a multi-cluster environment and the related troubleshooting.

## Multi-Cluster Environment Considerations

- Loader Nodes send data to all Foundations Nodes in the Ocient® System.
- The distribution of data loaded to each cluster is proportional to its total capacity.
- Every Loader Node loads to every cluster that belongs to the storage space of the target tables. Depending on the location of the tables, the database or schema could contain multiple storage spaces.
- Multiple storage clusters can share the same storage space. However, a storage cluster can only belong to one storage space.

> Dropping a cluster is not supported in an Ocient System that contains multiple storage clusters. However, you can drop a cluster in a system that contains only one cluster.

## Troubleshooting Considerations

- If a cluster shuts down, the load stops and provides results after the cluster is available again.
- The load is tolerant of Loader Node failures as the load can make progress when at least one Loader Node is still available.
- Before adding or removing a node, storage drive, or cluster, you must stop the load. Stop the LAT and any `CREATE TABLE AS SELECT` or `INSERT INTO SELECT` SQL statements. Otherwise, the load fails.

# Alter Default Data Pipeline Behavior

Use the ALTER SYSTEM ALTER CONFIG SQL command in Ocient to tune data pipeline parameters such as execution time, partition counts, and type inference.

An administrator might configure some parameters that control the behavior of data pipelines to modify the default behavior across the Ocient® System or specific nodes. You can use the `ALTER SYSTEM ALTER CONFIG` SQL statements to control the configuration parameters.

## Syntax

```sql
ALTER SYSTEM ALTER CONFIG SET 'sql.pipelineparameters.parameter_name' 'parameter_va
```

| Parameter | Data Type | Description |
|---|---|---|
| `parameter_name` | string | The name of the pipeline parameter, either general or specific to the BINARY format. |
| `parameter_value` | string | The value for the pipeline parameter. |

## General Parameters

| General Parameter Name | Default | Data Type | Required Value and Description |
|---|---|---|---|
| `sql.pipelineparameters.targetTimePerExtractorTask` | 600 | `UINT64_T` | Target execution time in seconds for `run_extractor` tasks for file loads. |
| `sql.pipelineparameters.defaultPartitionsPerExtractorTask` | -1 | `INT` | Number of partitions per task. If you set this parameter to -1, the number is based on available CPU cores. |
| `sql.pipelineparameters.defaultExtractorCores` | -1 | `INT` | Number of cores to use in a task.<br>If you set this parameter to |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| General Parameter Name | Default | Data Type | Required Value and Description |
|---|---|---|---|
| | | | -1, the number is based on available CPU cores. |

### Binary Format Parameters

You can modify these parameters to change the default behavior of the BINARY data format extraction.

| Binary Format Parameter Name | Default | Data Type | Required Value and Description |
|---|---|---|---|
| `sql.pipelineparameters.extract.binary.defaultEndianness` | `big` | string | The endianness of transforms when you do not specify it in another way.<br>Supported values are `big` or `little`. |
| `sql.pipelineparameters.extract.binary.defaultCharset` | ibm1047 | string | Determines the default character set to use when you load data in the `BINARY` format. |
| `sql.pipelineparameters.extract.binary.defaultAutoTrimPadding` | true | Boolean | Determines the default for whether a padding character should be trimmed when decoding data in the `BINARY` format to a string. |
| `sql.pipelineparameters.extract.binary.defaultPaddingCharacter` | ’ ‘ | `CHAR` | Determines the default padding character to trim from the end of a string when decoding data in the `BINARY` format.<br>This parameter is effective only if the `extract.binary.defaultAutoTrimPadding` parameter is set to `true`. |

### Examples

Set the target execution time for the extractor task to 600 seconds.

SQL

```
ALTER SYSTEM ALTER CONFIG SET 'sql.pipelineparameters.targetTimePerExtractorTask' 6
```

Set the default endianness of transforms to little endian for the BINARY extract.

SQL

```
ALTER SYSTEM ALTER CONFIG SET 'sql.pipelineparameters.extract.binary.defaultEndiann
```

The configuration values only go into effect after the `ALTER` SQL statement succeeds and you restart the affected nodes.

# Configuration Settings for Data Pipelines

Reference for Ocient data pipeline configuration settings, including JVM memory, S3 timeouts, Kafka polling, Parquet memory limits, and file system access.

Data pipeline functionality enables the use of SQL statements to load data. You can use a variety of configuration settings to manage the load. See this table for the settings that you can use.

| Configuration Setting Parameter Name | Default | Data Type | Description |
|---|---|---|---|
| `streamloader.extractorEngineParameters.enabled` | `true` | BOOLEAN | Whether the Loader Node attempts to bootstrap the extractor Java® process for data pipelines on start-up. If you set this parameter to `true`, the Loader Node does not become active until the Java loading process has successfully started. |
| `streamloader.extractorEngineParameters.jvmMemoryConfiguration` | - `32g` for `initialHeap`<br>- `64g` for `maxHeap`<br>- `64g` for `maxDirect` | VARCHAR | The JVM® memory configuration to use for the extractor Java process. Use strings representing data sizes in SI format: 1 KiB, 5 MiB, etc. You must set the three memory options in the same statement.<br><br>**Example**<br>`ALTER SYSTEM ALTER CONFIG SET 'streamloader.extractorEngineParameters.jvmMemoryConfiguration.initialHeap' = '32g', 'streamloader.extractorEngineParameters.jvmMemoryConfiguration.maxHeap' = '64g', 'streamloader.extractorEngineParameters.jvmMemoryConfiguration.maxDirect' = '64g';` |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Configuration Setting Parameter Name | Default | Data Type | Description |
|---|---|---|---|
| `streamloader.extractorEngineParameters.restPort` | 8090 | INT | Use this parameter with the `streamloader.extractorEngineParameters.portOffset` parameter to form the REST port for the extractor. (External monitoring services like Telegraf™ can query the REST server for loading process metrics.) |
| `streamloader.extractorEngineParameters.portOffset` | 0 | INT | Use this parameter with the `streamloader.extractorEngineParameters.restPort` parameter to form the REST port of the extractor. (External monitoring services like Telegraf can query the REST server for loading process metrics.) |
| `streamloader.extractorEngineParameters.configurationOption.expect.empty.file.list` | `false` | BOOLEAN | Set this value to `false` to fail a file source data pipeline that finds no files to load instead of the load completing successfully with no data loaded. |
| `streamloader.extractorEngineParameters.configurationOption.pipeline.preview.rows.limit` | 1000 | INT | The maximum number of rows a `PREVIEW PIPELINE` SQL statement can return. For example, when you use this statement, if the specified `LIMIT` value exceeds this number, then the loading process throws an error. |
| `streamloader.extractorEngineParameters.configurationOption.engine.transform.udt.jarRootDirectory` | `/opt/ocient/current/lib/extractorengine_udt` | VARCHAR | The absolute path to the directory containing JARs for data pipeline functions. To install and enable a third-party library for using data pipeline functions, install the JAR package at this location on all Loader Nodes. Then, add the chosen fully-qualified class name to the IMPORT clause of the data pipeline function. For details, see **CREATE OR** |

| Configuration Setting Parameter Name | Default | Data Type | Description |
|---|---|---|---|
| | | | **REPLACE PIPELINE FUNCTION**. |
| `streamloader.extractorEngineParameters.configurationOption.engine.external.jdbc.jarRootDirectory` | `/opt/ocient/current/lib/extractorengine_jdbc` | VARCHAR | The absolute path to the directory containing JARs for external source lookup functionality. For details, see **Load Data from External Sources in Data Pipelines**. |
| `streamloader.extractorEngineParameters.configurationOption.source.record.max.size` | Dynamically calculated value at start-up based on the number of processors and amount of memory available to the JVM | BIGINT | The maximum source record size, in bytes, that the loading process tolerates before throwing an error. |
| `streamloader.extractorEngineParameters.configurationOption.s3.region` | `us-east-1` | VARCHAR | The default region for Amazon® Web Services℠ (AWS℠) S3 file sources. |
| `streamloader.extractorEngineParameters.configurationOption.s3.force.path.style.access` | `false` | BOOLEAN | Set this value to `true` to use path-style access for all S3 file sources. The default is a virtual-hosted style. |
| `streamloader.extractorEngineParameters.configurationOption.s3.force.path.style.access.if.endpoint.overridden` | `true` | BOOLEAN | Set this value to `true` to use path-style access for S3 file sources that specify endpoints. (The system still uses virtual-hosted style access for sources without endpoint overrides unless you set `streamloader.extractorEngineParameters.configurationOption.s3.force.path.style.access` to `true`). |
| `streamloader.extractorEngineParameters.configurationOption.s3.retries.count` | 10 | INT | The number of retries for the S3 file source client. |
| `streamloader.extractorEngineParameters.configurationOption.s3.n` | 0 | INT | The timeout value for read operations, in seconds, for the S3 file source client. `0` means do not perform a timeout. |

| Configuration Setting Parameter Name | Default | Data Type | Description |
| --- | --- | --- | --- |
| `etty.read.timeout.seconds` | | | |
| `streamloader.extractorEngineParameters.configurationOption.s3.netty.max.concurrency` | 50 | INT | Maximum number of allowed concurrent requests for the S3 file source client. |
| `streamloader.extractorEngineParameters.configurationOption.awssdk.backoff.strategy.base.delay.seconds` | 1 | INT | The base amount of time, in seconds, for calculating the time the S3 file source client waits before retrying a failed request. The range of values that the calculated time can achieve increases exponentially with each failure. You can set the maximum value using the `streamloader.extractorEngineParameters.configurationOption.awssdk.backoff.strategy.max.backoff.seconds` parameter. |
| `streamloader.extractorEngineParameters.configurationOption.awssdk.backoff.strategy.max.backoff.seconds` | 20 | INT | The maximum amount of time the S3 file source client waits before retrying a failed request. |
| `streamloader.extractorEngineParameters.configurationOption.awssdk.max.pending.connection.acquires` | 20000 | INT | The maximum number of pending connection acquires that the S3 file source client allows. |
| `streamloader.extractorEngineParameters.configurationOption.awssdk.connection.timeout.seconds` | 10 | INT | The amount of time, in seconds, that the S3 file source client waits when initially establishing a connection. |
| `streamloader.extractorEngineParameters.configurationOption.awssdk.connection.max.idle.timeout.seconds` | 300 | INT | The maximum amount of time, in seconds, that the system allows a connection established by the S3 file source client to remain open while idle. |
| `streamloader.extractorEngineParameters.con` | 300 | INT | The amount of time, in seconds, that the S3 file source |

| Configuration Setting Parameter Name | Default | Data Type | Description |
| --- | --- | --- | --- |
| `figurationOption.awssdk.connection.acquisition.timeout.seconds` | | | client waits when acquiring a connection from the pool. |
| `streamloader.extractorEngineParameters.configurationOption.kafka.poll.timeout.msec` | 1000 | BIGINT | The amount of time, in milliseconds, that a consumer for a pipeline with an Apache® Kafka® source waits for records to become available during a poll operation. |
| `streamloader.extractorEngineParameters.configurationOption.kafka.assign.timeout.msec` | 20000 | BIGINT | The amount of time, in milliseconds, that a `PREVIEW PIPELINE` SQL statement waits for partitions to be assigned to the consumer on a pipeline with a Kafka source. If the system does not assign any partitions when the timeout elapses, then the `PREVIEW PIPELINE` statement terminates without data processing. |
| `streamloader.extractorEngineParameters.configurationOption.kafka.activate.timeout.msec` | 5000 | BIGINT | The amount of time, in milliseconds, that a `PREVIEW PIPELINE` SQL statement waits for a partition to receive records on a pipeline with a Kafka source. |
| `streamloader.extractorEngineParameters.configurationOption.arrow.max.native.memory.usage.bytes` | 23756537856 | BIGINT | The default maximum native memory usage, in bytes, for the Apache® Parquet™ reader. |
| `streamloader.extractorEngineParameters.configurationOption.arrow.max.java.buffer.memory.usage.bytes` | 15837691904 | BIGINT | The default maximum buffer memory usage, in bytes, for the Parquet reader. |
| `streamloader.extractorEngineParameters.configurationOption.filesystem.access.directories` | `/tmp` | VARCHAR | Comma-separated list of directories where you can load server file system data.<br><br>Each directory must exist.<br><br>All files must be located within |

| Configuration Setting Parameter Name | Default | Data Type | Description |
| --- | --- | --- | --- |
| | | | one of the directories.<br><br>By default, you can load from the `/tmp` directory. |
| `streamloader.extractorEngineParameters.configurationOption.kerberosConfig` | None | VARCHAR | The absolute path to the Kerberos configuration file ( `krb5.conf` ) that the loading process uses to authenticate to Apache® Hadoop® Distributed File System (HDFS) sources.<br><br>For help locating the file, see **Locating the krb5.conf Configuration File**. If you do not set this parameter, the loading process searches the default operating system locations, such as the `/etc/krb5.conf` file on Linux®.<br><br>This parameter affects all data pipelines that run on the Loader Node. For details, see **Kerberos Authentication for HDFS Sources**. |

# Configure Data Pipeline Logging

Adjust log levels for Ocient data pipelines with the ALTER SYSTEM ALTER LOG LEVEL SQL command to troubleshoot loading issues without impacting performance.

You can troubleshoot data pipelines using the standard logging mechanism in Ocient®.

Set these log levels in consultation with Ocient Support because this setting might impact performance.

## Modify the Level of Logging

Execute these two SQL statements in this order to bump up the log message.

First, set the log level.

```SQL
ALTER SYSTEM ALTER LOG LEVEL SET 'log4j' 'EDEBUG';
```

Then, set the level for the logging configuration.

```SQL
ALTER SYSTEM ALTER CONFIG SET 'streamloader.extractorEngineParameters.loggingConfig
```

If the log level of the first SQL statement is lower than the log level of the second SQL statement, the system loses log entries.

It is also possible to repeat the second SQL statement for different package names, such as:

- `ALTER SYSTEM ALTER CONFIG SET 'streamloader.extractorEngineParameters.loggingConfig.com.ocient.extractor.allowLevel' 'Info';`

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- `ALTER SYSTEM ALTER CONFIG SET 'streamloader.extractorEngineParameters.loggingConfig.com.ocient.extractor.engine.allowLevel' 'Trace';`

## Valid Log Levels

This table provides an overview of the log levels you can specify for the `ALTER SYSTEM ALTER LOG LEVEL SET` SQL statements with the `streamloader.extractorEngineParameters.loggingConfig` keys. The necessary log level for `log4j` must be set accordingly to at least the value specified in the column for the `log4j` level.

| **Log Level of** `streamloader.extractorEngineParameters.loggingConfig` | **Derived Level for** `log4j` |
|---|---|
| FATAL | ERROR |
| ERROR | ERROR |
| WARN | WARN |
| INFO | INFO |
| DEBUG | DEBUG |
| TRACE | EDEBUG |

## Reset the Log Level

To reset the log level after you reproduce a problem, execute these SQL statements.

SQL

```
ALTER SYSTEM ALTER CONFIG RESET 'streamloader.extractorEngineParameters.loggingConf
ALTER SYSTEM ALTER CONFIG RESET 'log4j';
```

System Administration

# Air-Gapped Environment with an Ocient System

Deploy and operate an Ocient System in an air-gapped environment to protect sensitive data, with no special configuration required for full isolation.

An air gap is a security measure that physically isolates a computer or network from any other network, including the internet. This isolation removes wired or wireless connections between the isolated system and any external and potentially unsecured networks. Organizations that handle highly sensitive information, such as government agencies, financial institutions, and critical infrastructure operators, use air-gapped environments to protect against various security incidents.

Ocient® supports using an Ocient System in an air-gapped environment without any special configuration. Here, you can find the general workflow for using an Ocient System in an air-gapped environment and the required installation steps.

## Work with an Ocient System in an Air-Gapped Environment

This workflow shows the high-level steps to set up an Ocient System in an air-gapped environment.

1. Ensure that your drive firmware and operating system is up to date.
2. Install and configure an Ocient System in a connected environment where you can download the required files from the internet.
3. Disassemble the cluster.
4. Pack and deliver the hardware to your secured location.
5. Reassign a new IP address.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

6 Reassign a new hostname.

7 Bootstrap the system again.

# Install an Ocient System in an Air-Gapped Environment

Follow these steps to install the Ocient System in an air-gapped environment. These steps assume that you have met the system requirements for installation.

### 1 Bootstrap the First Node

#### Bootstrap the Node

Connect to the initial SQL Node with the username and password of your server and the IP address of your node. This example connects as the administrator `admin` to the IP Address `10.10.10.10`.

Shell

```
ssh admin@10.10.10.10
```

Use your preferred text editor with `sudo` to create the `/var/opt/ocient/bootstrap.conf` file as root with these contents.

**`/var/opt/ocient/bootstrap.conf` example**

YAML

```
initialSystem: true
```

Start the database.

Shell

```
sudo systemctl start rolehostd
```

Verify that the node and the service is active by executing this status command.

Shell

```
systemctl status rolehostd

rolehostd.service - Rolehostd daemon startup
     Loaded: loaded (/etc/systemd/system/rolehostd.service; enabled; vendor
     Active: active (running) since Wed 2022-01-26 23:31:36 UTC; 7s ago
     ...
```

If the `rolehostd` service is running, you can also check the Ocient logs on your node. Search and ensure there are no [ERROR] log messages.

Shell

```
tail -f /var/opt/ocient/log/rolehostd.log
```

### Verify Connection to the SQL Node

At this point, you have a running database with a single node. You should be able to connect to the database using JDBC or `pyocient` and execute commands.

Every new system starts with a `system` database. To connect to a new system, use the username and password configured in the `bootstrap.conf` file or the username `admin@system` and password `admin` if none were provided.

For example, assume your node named `sql0` has an IP address of `10.10.0.1`. Use the JDBC driver CLI to connect with this connection string.

Shell

```
connect to jdbc:ocient://10.10.0.1:4050/system user "myuser@system" using "
```

To see the roles running on the single node, execute this query.

SQL

```sql
select name, operational_status, software_version, array_agg(service_role_t
        from sys.node_status as ns
        left join sys.nodes as n  on ns.node_id = id
        left join sys.service_roles as sr on sr.node_id = n.id
        group by name, operational_status,software_version;
```

The initial node should be listed as running the `sql`, `admin`, `health`, and `operatorvm` roles. If all of these roles are present and the node is Active, you can proceed to the next step to bootstrap the remaining nodes.

### 2 Bootstrap the Remaining Nodes

Performing the bootstrapping process on the remaining nodes is identical on all nodes. The remaining nodes can be bootstrapped in any order.

On each node, log in using SSH and use your text editor with `sudo` to create the file `/var/opt/ocient/bootstrap.conf` that contains this text by replacing `<FIRST_NODE_IP_ADDRESS>` with the IP address of the initial node you created in Step 1.

**`/var/opt/ocient/bootstrap.conf` example**

YAML

```yaml
adminHost: <FIRST_NODE_ADDRESS>
nodeToken: <token_from_GET_NODE_TOKEN>
```

`<FIRST_NODE_ADDRESS>` is the DNS name or IP address of the initial node. Generate a `nodeToken` value by executing the `GET NODE TOKEN` SQL statement using a database connection to the initial node. Each token is single-use, so you must generate a separate token for every joining node. The default token lifetime is 15 minutes. Generate each token shortly before starting the corresponding node, or specify a longer time-to-live (TTL) if needed.

© 2026 Ocient, Inc

You can obtain the IP Address of the initial node by executing `ifconfig` on that node.

You can also use `adminUserName` and `adminPassword` instead of `nodeToken`, but this approach is deprecated. Use node tokens for improved security. If the password for the system administrator has changed, set the correct username and password in `bootstrap.conf`.

On each node, start the database.

Shell

```
sudo systemctl start rolehostd
```

When you replace Foundation Nodes, the Ocient System removes the prior node after the creation of the new node. Some queries of the system catalog tables might not return results until the prior node is removed.

At this point, all the remaining nodes are not configured with any roles. After all nodes have been started, you should see them when you execute this query with only the `health` role listed. This query uses the `sys.node_status`, `sys.nodes`, and `sys.service_roles` system catalog tables to retrieve node information for the node name, operation status, version, and all service role types. The query uses the ARRAY_AGG function to retrieve the service role type for all rows.

SQL

```
SELECT name, operational_status, software_version, array_agg(service_role_t
    FROM sys.node_status AS ns
    LEFT JOIN sys.nodes AS n ON ns.node_id = id
    LEFT JOIN sys.service_roles AS sr ON sr.node_id = n.id
    GROUP BY name, operational_status,software_version;
```

# Remove a Cluster in an Air-Gapped Environment

Use this information and workflow to remove a cluster by shutting down all Ocient processes and erasing the drives and data.

> The system administrator must download the `sedutil-cli` utility used in this workflow.

You can classify the drives in an Ocient System in two categories based on their usage.

- Operating System (OS) drives: These drives contain the installation of the operating system and software, including the OcientAIQ™ Unified Data Platform. A system might have a single physical OS drive or an OS installed on a RAID disk created by using more than one drive. The OS drives on nodes with the administrator role (Metadata and possibly SQL Nodes) also store configuration information related to the Ocient System that can include:
  - Node names
  - Node IP addresses
  - User data mapping information for compressed columns
  - Encryption keys for the data drives (unless the keys are under the control of an external key management system)
- Data drives: The data drives are present in all types of nodes except the node running only the administrator role. On the Foundation Node, the data drives store tables. On SQL Nodes, the data drives store transient query information. And, on Loader Nodes, the data drives store transient loading information.

The data drives in the Ocient System are exclusively NVMe drives. The OS drives can be NVMe or SSD. These drives can support The Computing Group (TCG) Opal Specification or not support it. The type of drive (Opal-supported or not) determines how the system removes all data on the drive. Follow these steps to remove a cluster for Opal-supported drives. To remove data for Opal-supported drives, follow these steps.

> These steps irreversibly remove the data. Follow these steps after you ensure that you no longer need the applicable data from the system.

1. Stop the Ocient processes running on the nodes using these commands.

For Loader Nodes, use this command. The command combines two commands that stop all processes related to loading.

Shell

```
sudo systemctl disable lat && sudo systemctl stop lat
```

For all types of nodes, use this command. The command combines two commands where the first command stops processing on all nodes and the second command stops the main Ocient System process.

Shell

```
sudo systemctl disable rolehostd && sudo systemctl kill -s SIGKILL rolehost
```

2 Bind the data drives to an NVMe driver so that the drives become visible to the OS.

Shell

```
sudo /opt/ocient/scripts/nvme-driver-util.sh bind-nvme
```

3 Run this command for each data drive. The impacted drives are the drives displayed as their association change from `uio` drivers to `nvme` drivers. You can see the `nvme` drive association by running the `/opt/ocient/scripts/nvme-driver-util.sh` script. All data drives are erased.

> You can move drives to another node with the `sedutil-cli` utility if the nodes are already powered off and you cannot power them on. Use the same command to erase the drive: `sedutil-cli -n --revertTPer admin /dev/nvmeXn1` .

Shell

```
sedutil-cli -n --revertTPer admin /dev/nvmeXn1
```

> You cannot securely erase the OS drives while the OS is running. You can either use the secure erase facility from BIOS or move drives to an external host with a utility approved by your organization for the remove operation.

# Ocient MCP Server

Connect AI agents to Ocient with the Ocient MCP Server. Discover schemas, execute SQL statements, and extend the tool surface with user-defined MCP tools.

The Model Context Protocol (MCP) is an open standard that gives AI agents a consistent way to discover and invoke tools. The Ocient® MCP Server implements this standard for the Ocient System. Using the Ocient MCP Server, AI agents and AI-powered code editors can explore schemas and tables, execute SQL statements, and invoke custom tools that you define in the database using SQL.

Ocient distributes the MCP server as the Python® package `ocientmcp`. The package works with any client that implements the MCP specification. The server returns all results as structured JSON.

> A single Ocient MCP Server instance connects to one Ocient System. To use AI agents with multiple Ocient Systems, execute one server instance for each system.

## Ocient MCP Server and Its Tools

The Ocient MCP Server delegates tool discovery and tool execution to the connected Ocient System. The database stores the definitions of all MCP tools — both the system tools that ship with the Ocient System and the user-defined tools that you create. Also, the server can discover them dynamically at runtime by querying the `sys.mcp_tools` system catalog table.

This architecture has these characteristics:

- The server itself defines only the `execute_statement` tool. The server discovers all other tools by querying the `sys.mcp_tools` system catalog table, exposes them to MCP clients as standard MCP tools, and executes them using the `CALL MCP TOOL` SQL statement.
- New user-defined tools become available to MCP clients immediately after you create them, without a server upgrade or restart.
- The Ocient System governs all tools with standard access control privileges.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- Because all tools are remote, no tools are available while the connection to the Ocient System is down. In this case, the server returns a clear connection-failure error as tool output so that the AI agent can report the issue.

## Prerequisites

- Access to an Ocient System with a database user account.
- The **uv** Python package manager, which provides the `uvx` command.
- Network connectivity from the machine that executes the server to the SQL port of the Ocient System.

## Deployment Models

The `ocientmcp` package provides three entrypoints.

| Entrypoint | Transport | Description |
|---|---|---|
| `ocientmcp-stdio` | Stdio | Executes the server as a local subprocess of the MCP client. Each client process communicates with one server process, and each server process maintains one Ocient connection. |
| `ocientmcp-http` | Streamable HTTP | Executes the server as a remote service that multiple MCP clients share. Each connected client has its own logical Ocient connection and session. |
| `ocientmcp-http-proxy` | Stdio proxy to Streamable HTTP | Wraps a remote Streamable HTTP server in a local Stdio subprocess for MCP clients that do not support the Streamable HTTP transport natively. |

The server supports the Stdio and Streamable HTTP transports of the current MCP specification. The server does not support the legacy HTTP with Server-Sent Events (SSE) transport.

### Deploy Locally with Stdio

Configure your MCP client to launch the `ocientmcp-stdio` entrypoint. The server supports two authentication modes and determines its one Ocient connection from environment variables in this order:

1. If you set the `OCIENT_DSN` environment variable, the server connects using the full Data Source Name (DSN) and ignores the SSO environment variables.
2. Otherwise, the server requires the `OCIENT_HOSTS` and `OCIENT_DATABASE` environment variables and connects using single sign-on (SSO).

### SSO Mode (recommended)

On the first launch, your browser opens to the SSO identity provider of your organization, such as OKTA® or Google®. After you authenticate, the server caches the security token at `~/.cache/ocientmcp/mcp-token-cache.json` so that subsequent launches reconnect silently.

This example shows an MCP client configuration that connects with SSO.

JSON

```
{
  "mcpServers": {
    "ocient": {
      "command": "uvx",
      "args": ["--from", "ocientmcp", "ocientmcp-stdio"],
      "env": {
        "OCIENT_HOSTS": "host1.ocient.com,host2.ocient.com",
        "OCIENT_DATABASE": "mydb"
      }
    }
  }
}
```

SSO mode supports these optional environment variables.

| Environment Variable | Default | Description |
|---|---|---|
| `OCIENT_PORT` | `4050` | The SQL port of the Ocient System. |
| `OCIENT_TLS` | `unverified` | The Transport Layer Security (TLS) mode for the connection: `off` (off), `unverified` (unverified), or `on` (on). |
| `OCIENT_IDENTITY_PROVIDER` | Server-configured | The name of the SSO identity provider, for example, `okta` for Okta or `google` for Google. |

You can also pass these options as the `--port`, `--tls`, and `--identity-provider` command-line options, respectively.

> If a cached SSO token expires, delete the `~/.cache/ocientmcp/mcp-token-cache.json` file and restart the server to authenticate again.

### DSN Mode

This example shows an MCP client configuration that connects with a DSN.

JSON

```
{
  "mcpServers": {
    "ocient": {
      "command": "uvx",
      "args": ["--from", "ocientmcp", "ocientmcp-stdio"],
      "env": {
        "OCIENT_DSN": "ocient://username:password@host:port/database"
      }
    }
  }
}
```

The server opens the connection on the first tool invocation and reuses the connection for all subsequent calls. To connect to a different database, update the environment variables and restart the server.

## Deploy Remotely with Streamable HTTP

A database administrator starts the server with the `ocientmcp-http` entrypoint and an authentication file. If you omit the `--auth-file` option, the server looks for the file at `/var/opt/ocient/mcp/auth.yaml`. For details about the authentication file, see **Authentication**.

Shell

```
uvx ocientmcp-http --auth-file /var/opt/ocient/mcp/auth.yaml
```

Users then configure their MCP clients with the URL of the remote server and an API key from the authentication file:

- If the MCP client supports Streamable HTTP natively, configure the client directly with the server URL and pass the API key as a Bearer token.
- If the MCP client supports only the Stdio transport, configure the `ocientmcp-http-proxy` entrypoint with the `--url` option and pass the API key in the `OCIENT_MCP_API_KEY` environment variable.

This example shows an MCP client configuration that uses the proxy entrypoint.

JSON

```
{
  "mcpServers": {
    "ocient": {
      "command": "uvx",
      "args": [
        "--from", "ocientmcp",
        "ocientmcp-http-proxy",
        "--url", "http://localhost:8000/mcp"
      ],
      "env": {
        "OCIENT_MCP_API_KEY": "secret_key_abc_123"
      }
    }
  }
}
```

# Authentication

## Stdio Authentication

With the Stdio transport, credentials flow through the environment. The server connects with a DSN in this format when you set the `OCIENT_DSN` environment variable.

Text

```
ocient://username:password@host:port/database
```

If you do not set `OCIENT_DSN`, the server connects using browser-based SSO with the `OCIENT_HOSTS` and `OCIENT_DATABASE` environment variables. For the optional SSO environment variables, see **Deploy Locally with Stdio**.

The server does not log or echo the DSN string because the DSN contains the username and password.

## Streamable HTTP Authentication

With the Streamable HTTP transport, a database administrator configures a YAML authentication file and starts the server with the `--auth-file` option pointing to that file. The file maps API keys to connection credentials, where each API key maps to one of these values.

- A DSN connection string.
- An object with a `dsn` key for SSO access and a `token_source` key with the path of the JSON file for the SSO token. Only machine-to-machine SSO is supported for the Streamable HTTP transport, and the Google identity provider is supported for SSO access.

YAML

```yaml
# /var/opt/ocient/mcp/auth.yaml

# DSN access
secret_key_abc_123: ocient://user1:pass1@host:port/db1
secret_key_abc_456: ocient://user2:pass2@host:port/db2

# SSO access
secret_key_sso_123:
  dsn: ocient://user:password@host:port/database?handshake=sso&identityprovider=goc
  token_source: /path/to/token_source.json
```

Administrators can add, modify, and delete keys in the authentication file to manage access.

Follow these security practices for remote deployments:

- The authentication file must have `600` file permissions because the file contains plain-text DSNs. The server validates the file permissions at startup.

- API keys are Bearer tokens over HTTP. Use TLS for production deployments. The server logs a warning if it executes over HTTP without TLS.

## Connection Behavior

The server can manage connections automatically with these actions:

- For the Stdio transport, a single DSN or SSO configuration maps to one persistent connection. The server opens the connection on the first tool invocation and reuses it for all subsequent calls.
- For the Streamable HTTP transport, each API key maps to one set of connection credentials, and each connected client has its own logical connection and session. Because multiple connections can be open concurrently, idle connections have a 30-minute time-to-live, after which the server closes them. The server reconnects automatically on the next tool invocation.
- If the Ocient connection goes down during a session, the server returns a connection-failure error as tool output instead of a transport-level failure, so that the AI agent can inform you of the issue.

## Tool Reference

### Static Tools

The server defines one static tool named `execute_statement` in its own codebase. This tool is always available while the server executes.

| Tool | Arguments | Description |
|---|---|---|
| `execute_statement` | `statement`, `parameters` (optional) | Executes an arbitrary SQL query or command against the connected Ocient System and returns the result set or row count as structured data. The optional `parameters` argument specifies values for a parameterized SQL statement. |

On SQL errors such as syntax errors, permission errors, or missing objects, the `execute_statement` tool returns a descriptive tool error that contains the Ocient error message instead of a transport-level failure. The error messages are descriptive enough for an AI agent to self-correct and retry.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Dynamic Tool Discovery

The server discovers all other tools dynamically by querying the `sys.mcp_tools` system catalog table and exposes them to MCP clients as standard MCP tools. The MCP name of each discovered tool is the schema and tool name joined by two underscores. For example, the system tool `show_tables` appears to MCP clients as `sys__show_tables`, and a user-defined tool `analytics.busiest_hours` appears as `analytics__busiest_hours`. AI agents invoke discovered tools directly, without a separate discovery step.

When an AI agent invokes a discovered tool, the server executes the tool in the database using the `CALL MCP TOOL` SQL statement with the privileges of the connected user.

## System Tools

System tools ship with the Ocient System in the `sys` schema and belong to the `System Information` toolset. These tools are always visible, and you cannot drop them. Every user has the EXECUTE privilege on system tools by default, and a security administrator can revoke and regrant this privilege. The system scopes results to the privileges of the caller.

| Tool | Arguments | Description |
|---|---|---|
| `show_columns` | `schema` for a schema or `table_name` for a table | Shows all columns in the specified schema or table. |
| `show_schemas` | None | Shows all user-defined schemas in the database. |
| `show_system_schemas` | None | Shows the system schemas in the database. |
| `show_system_tables` | None | Shows all system tables and views ( `sys` and `information_schema` ). |
| `show_tables` | `schema` (optional) | Shows all user-defined tables in the database, optionally filtered by schema. |
| `show_views` | `schema` (optional) | Shows all user-defined views in the database, optionally filtered by schema. |

## User-Defined MCP Tools

You can extend the MCP tool surface with your own tools. A user-defined MCP tool is a self-contained SQL definition that the Ocient System stores as a standard metadata object. After you create a tool, any connected MCP client can discover and invoke it by name, without knowing the underlying query logic.

Manage user-defined tools with these SQL statements. For the complete syntax, parameters, and examples, see **Model Context Protocol Tools**.

| SQL Statement | Description |
|---|---|
| `CREATE MCP TOOL` | Creates a user-defined MCP tool from a SQL definition. |
| `CALL MCP TOOL` | Executes a user-defined or system MCP tool with the specified arguments. |
| `DROP MCP TOOL` | Removes a user-defined MCP tool. |
| `EXPORT MCP TOOL` | Returns the `CREATE MCP TOOL` SQL statement that recreates a user-defined MCP tool. |

This example creates a tool that lists the user-defined tables within a schema. The `DESCRIPTION` clause provides the text that MCP clients display to AI agents, and the `TOOLSET` clause assigns the tool to a toolset with a string that can contain spaces. The tool body references its arguments with the `@` prefix.

SQL

```
CREATE MCP TOOL my_schema.my_tool(schema VARCHAR)
    DESCRIPTION 'This tool lists user-defined tables within a schema.'
    TOOLSET 'System Information'
    AS BEGIN TOOL
        RETURN SELECT * FROM information_schema.tables
        WHERE table_schema NOT IN ('sys', 'information_schema')
        AND table_type = 'BASE TABLE'
        AND (@schema IS NULL OR table_schema = @schema);
    END TOOL;
```

User-defined MCP tools have these characteristics:

- Tools support the SQL language for their definitions.
- Every tool has a toolset, which groups related tools.

- The `ALTER` statement is not supported for MCP tools. To change a tool, use the `CREATE OR REPLACE MCP TOOL` SQL statement.
- The tool object supports the CREATE, VIEW, DROP, and EXECUTE privileges.
- The `CALL MCP TOOL` SQL statement executes the SQL definition of the tool with the privileges of the caller. There is no privilege escalation.

The `sys.mcp_tools` system catalog table lists all MCP tools in the database, including system tools and user-defined tools, with their arguments, descriptions, toolsets, definitions, and tool types. For details, see **System Catalog**.

## Usage Considerations

Consider these caveats for privileges, workload management, limiting result sets, and generated queries:

- The system scopes all tool results to the privileges of the connected database user. For shared or agent-driven deployments, create a dedicated database user with the minimum privileges the agent requires, and revoke the EXECUTE privilege on any system tools you do not want the agent to use. For details, see **Data Control Language (DCL) Statement Reference**.
- SQL statements that AI agents submit through the MCP server execute like any other SQL statement and participate in workload management. You can use service classes to control the priority of agent-driven queries. For details, see **Workload Management and Service Classes**.
- AI agents can request large result sets. Where possible, define user-defined MCP tools that aggregate or limit results instead of exposing broad queries, and include `LIMIT` clauses in exploratory queries.
- Agent-driven queries appear in the `sys.queries` and `sys.completed_queries` system catalog tables like any other query. For details, see **System Catalog**.

## Limitations

The Ocien MCP Server has these limitations:

- A single server instance connects to one Ocient System. Multi-system routing is not supported.

- With the Stdio transport, connecting to a different database requires a server restart.
- The legacy HTTP with SSE transport is not supported.
- User-defined MCP tools support SQL definitions only.
- MCP tools do not support the `ALTER` statement.
- Only machine-to-machine SSO is supported for the Streamable HTTP transport.
- No tools are available while the connection to the Ocient System is down.

# Data Analytics Workflow Using the Ocient MCP Server

Incorporate the Ocient MCP Server into an end-to-end data analytics workflow with an AI agent, from loading data to analysis and reporting.

This tutorial shows how to incorporate the Ocient® MCP Server into an end-to-end data analytics workflow, from loading data to analysis and reporting. In this workflow, you converse with an AI agent or AI assistant in natural language, and the agent uses the MCP tools to inspect metadata and execute SQL statements against the Ocient System on your behalf.

The example workflow loads a data set of taxi trips from an Amazon® Web Services℠ (AWS℠) S3 bucket, analyzes the trips, and produces a summary report.

## Prerequisites

- An Ocient MCP Server connected to an Ocient System. For setup steps, see **Ocient MCP Server**.
- An MCP client, such as an AI assistant or an AI-powered code editor, that you configure to use the server.
- A database user with privileges to create tables, create data pipelines, and create MCP tools in the target schema.
- Source data in a supported data pipeline source, such as an S3 bucket.

### 1 Step 1: Verify the Connection.

Ask the agent a simple metadata question.

Prompt

```
What schemas exist in my Ocient database?
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

The agent invokes the `show_schemas` tool and lists the user-defined schemas that your privileges allow you to see. A successful response confirms that the MCP client, the server, and the database connection all work.

## 2 Step 2: Explore the Schema.

Before the agent writes SQL statements, it grounds itself in your actual metadata. Ask about the tables and columns you plan to analyze.

Prompt

```
What tables are in the analytics schema, and what columns does the trips ta
```

The agent invokes the `show_tables` and `show_columns` system tools to retrieve the table list and the column names, data types, and nullable properties. Because the agent reads the real metadata instead of guessing, its generated SQL statements reference correct object names and handle data types correctly. The agent can also query the `information_schema` views with the `execute_statement` tool to confirm additional type details.

## 3 Step 3: Load the Data.

Describe the data you want to load and where it lives.

Prompt

```
Load the CSV files in s3://example-bucket/taxi-trips/ into a new table name
analytics.trips. The files have a header row.
```

The agent inspects a sample of the source data, generates a `CREATE TABLE` SQL statement with appropriate data types, and generates a `CREATE PIPELINE` SQL statement to load the files. The agent executes both statements with the `execute_statement` tool, and then starts the load.

SQL

```
START PIPELINE trips_pipeline;
```

© 2026 Ocient, Inc

You can ask the agent to monitor the load progress. The agent queries the pipeline status views, such as `information_schema.pipeline_status`, and reports errors from the `sys.pipeline_errors` system catalog table if any records fail. For details about data pipelines, see **Load Data**.

## 4 Step 4: Analyze the Data.

Ask analytical questions in natural language.

Prompt

```
What are the 10 busiest pickup hours by total trips, and what is the averag
fare for each of those hours?
```

The agent generates and executes a SQL query.

SQL

```sql
SELECT HOUR(pickup_timestamp) AS pickup_hour,
       COUNT(*) AS total_trips,
       AVG(fare_amount) AS average_fare
FROM analytics.trips
GROUP BY pickup_hour
ORDER BY total_trips DESC
LIMIT 10;
```

If a query fails, the `execute_statement` tool returns the Ocient error message as a descriptive tool error, and the agent corrects the query and retries. You can iterate conversationally, for example, ask the agent to filter by date range, join reference tables, or apply machine learning model functions from **Machine Learning in Ocient**.

## 5 Step 5: Encapsulate the Analysis as an MCP Tool.

After you settle on an analysis that you want to reuse, ask the agent to wrap it in a user-defined MCP tool.

Prompt

```
Create an MCP tool named analytics.busiest_hours that takes a start date an
end date and returns the busiest pickup hours with average fares.
```

The agent executes a `CREATE MCP TOOL` SQL statement that stores the parameterized query as a metadata object in the database. From this point on, the MCP server automatically discovers the new tool and exposes it as `analytics_busiest_hours`, and any teammate or AI agent connected to the same Ocient System can invoke it by name, without knowing the underlying query logic. For an overview, see **User-Defined MCP Tools**. For the complete `CREATE MCP TOOL` syntax, see **Model Context Protocol Tools**.

## 6 Step 6: Generate a Report.

Ask the agent to summarize the results.

Prompt

```
Summarize the trip analysis as a short report with a table of the busiest h
and three key findings.
```

The agent invokes the analysis tools, collects the result sets, and composes the report in your conversation or in a file, depending on your MCP client. Because the tools are stored in the database, you can repeat this workflow on a schedule or from a custom agent. For details, see **Build an AI Agent with the Ocient MCP Server**.

# Build an AI Agent with the Ocient MCP Server

Build your own AI agent on the Ocient MCP Server. Connect with the MCP SDK, discover tools, execute SQL statements, and design a governed tool surface.

You can build your own AI agent that uses the Ocient® MCP Server as its data layer. An AI agent combines a large language model (LLM) with a set of tools in a loop: the model decides which tool to invoke, your agent code executes the tool, and the model uses the result to decide the next step. The Ocient MCP Server supplies the tools, so your agent can explore schemas, execute SQL statements, and invoke the custom tools that you define in the database — without any database-specific code.

## Agent Interaction with the MCP Server

An agent interacts with the Ocient MCP Server in this sequence:

1. The agent connects to the server and requests the tool list. The server returns `execute_statement` and all discovered tools, system tools and user-defined tools, with their MCP names (such as `show_tables`), argument schemas, and descriptions.
2. The agent passes the tool definitions to the LLM together with the user request.
3. The LLM selects a tool and provides the arguments. The agent invokes the tool through the MCP session.
4. The server executes the tool in the Ocient System and returns the result, which the agent passes back to the LLM.
5. The loop repeats until the LLM produces a final answer.

Because the database stores the tool definitions, the tool descriptions in the `sys.mcp_tools` system catalog table act as prompts for the LLM. Clear, specific tool descriptions improve how reliably the model selects and uses your tools.

## Connect to the Server from Python

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

This example uses the MCP Python® SDK to launch a local server with the Stdio transport, list the available tools, and execute a SQL statement.

Python

```python
import asyncio
import os

from mcp import ClientSession, StdioServerParameters
from mcp.client.stdio import stdio_client

server_params = StdioServerParameters(
    command="uvx",
    args=["--from", "ocientmcp", "ocientmcp-stdio"],
    env={"OCIENT_DSN": os.environ["OCIENT_DSN"]},
)

async def main():
    async with stdio_client(server_params) as (read, write):
        async with ClientSession(read, write) as session:
            await session.initialize()

            tools = await session.list_tools()
            for tool in tools.tools:
                print(f"{tool.name}: {tool.description}")

            result = await session.call_tool(
                "execute_statement",
                {"statement": "SELECT COUNT(*) FROM analytics.trips"},
            )
            print(result.content)

asyncio.run(main())
```

To connect to a remote server instead, use the Streamable HTTP client from the same SDK and pass your API key as a Bearer token. For deployment details, see **Deployment Models**.

## Add the Agent Loop

To turn the connection into an agent, pass the tool definitions from `list_tools` to your LLM provider as its available tools, and execute each tool invocation that the model requests through `session.call_tool`. Most LLM provider SDKs and agent frameworks accept MCP tool definitions directly or with a thin conversion layer, and many agent frameworks manage this loop for you when you register an MCP server as a tool source.

Follow these practices in the loop:

- Return tool errors to the model. The `execute_statement` tool returns Ocient error messages as descriptive tool errors, and the messages are descriptive enough for the model to correct its SQL statement and retry.
- Bound the loop with a maximum number of tool invocations to prevent runaway execution.
- Log each tool invocation and its SQL text for auditing. Agent-driven queries also appear in the `sys.queries` and `sys.completed_queries` system catalog tables.

## Design a Governed Tool Surface

The most reliable agents work with a small set of purpose-built tools instead of open-ended SQL. Use these techniques to shape what your agent can do.

- Create task-specific tools — Encapsulate approved queries as user-defined MCP tools with the `CREATE MCP TOOL` SQL statement. The agent invokes the tools by name with typed arguments, which removes whole categories of SQL generation errors. For the complete syntax, see **Model Context Protocol Tools**.
- Group tools into toolsets — Assign related tools to a toolset with the `TOOLSET` clause of the `CREATE MCP TOOL` SQL statement so that agents can work with a coherent set of capabilities, for example, a geospatial analysis toolset or a reporting toolset.
- Scope privileges — Connect the agent with a dedicated database user that has only the privileges the agent requires. Revoke the EXECUTE privilege on tools that the agent must not use. The `CALL MCP TOOL` SQL statement executes with the privileges of the caller, so the database enforces your access control on every invocation. For the MCP tool privileges, see **Data Control Language (DCL) Statement Reference**.

- Control query priority — Assign a service class to the agent user to manage the workload impact of agent-driven queries. For details, see **Workload Management and Service Classes**.

# Ocient Simulator

Use the Ocient Simulator to test queries, validate schemas, and prototype data pipelines in a lightweight local environment before deploying to production.

Ocient® provides a simulated database system upon request for development or local workloads with no performance requirements.

This simulator system is a lightweight package that emulates a complete Ocient System with these features:

- SQL port for connection using any of the supported connectors from Ocient.
- No NVMe drive or Linux® huge page requirements.

> To request access to an Ocient simulator, please contact Ocient Support.

## Prerequisites

The Ocient simulator has these hardware and software requirements:

### Hardware

- 64GB system RAM
- 64-bit Intel® architecture CPU (x86)
- Allocated disk storage equal to twice the size of the data to load.

> If you run the Ocient Simulator on a virtual machine, you must configure your virtual machine CPU to support AVX2 instructions by setting the CPU type to `host`.

### Software

- Docker® **Engine** version 20.10.10 or greater with **Docker Compose** version 1.9.0 or greater.

## Install the Ocient Simulator

© 2026 Ocient, Inc

Ocient distributes its simulator as the tarball `simulator_archive.tar`. Upon receiving the file, you can extract it and load the container images into the Docker daemon with the provided `load_all_images.sh` file.

> Some file names might differ based on the simulator release version.

1. From a terminal window, create a new empty directory.

   Shell

   ```
   mkdir simulator_workspace
   ```

   And then change the directory to the new one.

   Shell

   ```
   cd simulator_workspace
   ```

2. Copy or move the tarball file into the new directory.

3. Extract the file.

   Shell

   ```
   tar xf simulator_archive.tar
   ```

   The simulator package contains these files.

| File Name | Description |
| --- | --- |
| `configure.sql` | The system configuration script that bootstraps the simulator. |
| `docker-compose.yml` | The **Docker Compose file** that defines the containers that constitute the simulator system. |

| File Name | Description |
| --- | --- |
| `lat_client.tar`, `lat_simulator.tar`, `ocient_jdbc_image.tar`, `rolehostd_simulator.tar` | These Docker images comprise various components of the Ocient System. |
| `jdbc.sh` | The JDBC CLI launch script for connection to the SQL interface of the simulator. |
| `lat_client.sh` | The Loading and Transformation (LAT) client launch script. The LAT client is for backward compatibility. |
| `load_all_images.sh` | This script loads all the tarball files into the Docker daemon. |

4 Load the Ocient System tarball files for the simulator.

Shell

```
./load_all_images.sh
```

If you do not have access privileges to the Docker daemon, you might receive the `Permission denied` error when you run `docker` commands. Use `sudo` or add your user to the Docker group.

This output shows a successful load operation. The exact output of your simulator might differ depending on what version you download.

Shell

```
a0c3d7b00a1e: Loading layer [==================================>]  59.26MB
5d75db409355: Loading layer [==================================>]  329.6MB

Loaded image: ocient/rolehostd/simulator:23.0.0-1680124029
```

## Start and Configure the Cluster

Each Ocient simulator consists of a series of nodes running in their own Docker containers. The `docker compose` command enables networking, general administration, and orchestration of these nodes.

> The commands you use based on this section might differ with your Docker version.
>
> These steps use the `docker compose` command for the simulator setup. If you are using an older version of Docker with `docker-compose` (a dash instead of a space), use that instead.

1. Start the cluster using the `docker compose` command.

Shell

```
docker compose up -d
```

The cluster startup displays output that is similar to this output.

Shell

```
[+] Running 7/7
 ⠿ Network simulator_workspace_ocientdbnet      Created                  0.
 ⠿ Container simulator_workspace-sql-1          Started                 20.
 ⠿ Container simulator_workspace-foundation0-1  Started                 15.
 ⠿ Container simulator_workspace-foundation2-1  Started                 17.
 ⠿ Container simulator_workspace-foundation1-1  Started                 16.
 ⠿ Container simulator_workspace-loader-1       Started                 14.
 ⠿ Container simulator_workspace-lat-1          Started                  7.
```

Ensure that you run every command from the same directory where you extracted the `simulator_archive.tar.gz` archive.

2 Using the bundled JDBC CLI, connect to the cluster and run the contents of the `configure.sql` file that is distributed with the simulator.

The JDBC CLI is bundled with the simulator as the `jdbc.sh` script. Execute this script with no arguments after starting the cluster.

Shell

```
./jdbc.sh
```

After loading the JDBC CLI, the system prompts you to enter a username and password. The default simulator username and password are `admin@system` and `admin` .

You can also pass these credentials later in a CONNECT statement, for example:

`CONNECT TO jdbc:ocient://sql:4050/system USER admin@system USING admin;`

The interface switches to the JDBC CLI interactive mode, as indicated by the `Ocient>` prompt. Execute the configuration file.

JDBC CLI

```
source configure.sql;
```

The configuration displays output similar to this.

Shell

```
Connected to jdbc:ocient://sql:4050/system
Modified 0 rows
Modified 0 rows
Modified 0 rows
Warning: Node must be restarted for changes to take effect (the streamloader
Modified 0 rows
Modified 0 rows
Modified 0 rows
```

3 After completing its modifications, the simulator warns that it needs to restart for the changes to take effect. Quit the interactive mode.

JDBC CLI

```
quit
```

Restart the cluster.

Shell

```
docker compose restart
```

4 After the nodes restart, verify that the simulator has started and the `test` database is accessible by connecting to it with the JDBC CLI.

Launch the JDBC connector again.

Shell

```
./jdbc.sh
```

Connect to the `test` database in the JDBC CLI.

JDBC CLI

```
CONNECT TO jdbc:ocient://sql:4050/test;
```

The system displays a confirmation message upon a successful connection.

JDBC CLI

```
Connected to jdbc:ocient://sql:4050/test
```

## Load Data

The simulator cluster includes a Loader Node, which can load data from external sources, such as an Amazon® Web Services℠ (AWS℠) S3 bucket. This section demonstrates the creation of a basic table and pipeline, which you can then use to load data from a sample data set into a simulator database.

If you are not already in the JDBC CLI interactive mode, start it and connect to the `test` database using the steps in **Start and Configure the Cluster**.

1. Create a table to load. Enter this `CREATE TABLE` SQL statement. This table contains columns with various data types available in the Ocient System.

SQL

```sql
CREATE TABLE loading.data_type_coverage (
    col_bigint BIGINT NULL,
    col_binary BINARY(2) NULL,
    col_boolean BOOL NULL,
    col_char CHAR(4) NULL,
    col_date DATE NULL,
    col_decimal DECIMAL(18,4) NULL,
    col_double DOUBLE NULL,
    col_float FLOAT NULL,
    col_int INT NULL,
    col_int_array INT[] NULL,
    col_ipv4 IPV4 NULL,
    col_ip IP NULL,
    col_smallint SMALLINT NULL,
    col_point POINT NULL,
    col_linestring LINESTRING NULL,
    col_polygon POLYGON NULL,
    col_time TIME NULL,
    col_timestamp TIMESTAMP NULL,
    col_tinyint TINYINT NULL,
    col_tuple tuple<<INT, VARCHAR(255)>> NULL,
    col_uuid UUID NULL,
    col_varbinary VARBINARY(255) NULL,
    col_varchar VARCHAR(255) NULL
);
```

2 Create a data pipeline to load the data. Enter this `CREATE PIPELINE` SQL statement.

This pipeline loads gzip-compressed CSV files from an S3 bucket into the `data_type_coverage` table. The pipeline reads files matching the `**output*.csv.gz` pattern from the `ocient-docs` bucket, parses them as comma-delimited records with quoted fields and a header row, and maps each named header field to a target column.

The `EXTRACT` clause includes array and tuple delimiter settings so the parser can correctly interpret complex-type values embedded in the CSV data. The `SELECT` clause applies explicit type conversions where needed — for example, ensuring that

the `col_double` and `col_float` columns properly handle `NaN` values and stripping formatting characters from the timestamp field.

For details on Ocient data pipelines, see **Data Pipelines**.

SQL

```sql
CREATE PIPELINE data_type_coverage_pipeline
SOURCE S3
    ENDPOINT 'https://s3.us-east-1.amazonaws.com'
    BUCKET 'ocient-docs'
    FILTER 'all_data_types/small/**output*.csv.gz'
    COMPRESSION_METHOD 'gzip'
EXTRACT
    FORMAT CSV
    NUM_HEADER_LINES 1
    FIELD_OPTIONALLY_ENCLOSED_BY '"'
    OPEN_OBJECT '('
    CLOSE_OBJECT ')'
INTO loading.data_type_coverage
SELECT
    $1 AS col_bigint,
    $2 AS col_binary,
    $3 AS col_boolean,
    $4 AS col_char,
    $5 AS col_date,
    DECIMAL($6, 18, 4) AS col_decimal,
    DOUBLE(IF(LOWER($7) = 'nan', NULL, $7)) AS col_double,
    FLOAT(IF(LOWER($8) = 'nan', NULL, $8)) AS col_float,
    $9 AS col_int,
    INT[]($10) AS col_int_array,
    $11 AS col_ipv4,
    $12 AS col_ip,
    $13 AS col_smallint,
    $14 AS col_point,
    $15 AS col_linestring,
    $16 AS col_polygon,
    $17 AS col_time,
    REPLACE(REPLACE($18, 'T', ' '), 'Z', '')
        AS col_timestamp,
    $19 AS col_tinyint,
    $20 AS col_tuple,
    $21 AS col_uuid,
    VARBINARY(IF($22 IS NULL, NULL,
        IF(LENGTH($22) % 2 = 1, CONCAT('0', $22), $22)))
        AS col_varbinary,
    $23 AS col_varchar;
```

3. Start the pipeline to load the data.

```sql
START PIPELINE data_type_coverage_pipeline;
```

The sample data set can take about 30 seconds to fully load.

4. Verify the `data_type_coverage` table is present.

```shell
LIST TABLES;
```

Verify the row count in the table using this SQL statement.

```sql
SELECT COUNT(*) FROM loading.data_type_coverage;
```

If the load operation is complete, the output table shows a count of about 100,000 rows.

```text
count(*)
--------------------
100000

Fetched 1 row
```

5. When you are confident your data is fully loaded, you can delete the pipeline using the `DROP PIPELINE` SQL statement.

SQL

```
DROP PIPELINE data_type_coverage_pipeline;
```

Now that your Ocient simulator is loaded with data, you can add integrations for user interfaces, visualizations, and other applications. For details, see **Ocient Integrations**.

## Access the Ocient Management UI

The Ocient simulator includes the Ocient Management UI, which provides a web-based interface for monitoring your system, executing queries, and building data pipelines. The `configure.sql` script enables the UI endpoint during cluster setup.

After completing the cluster configuration and restart described in **Start and Configure the Cluster**, follow these steps to access the Management UI.

### 1 Access the UI

The system hosts the UI over HTTPS on port `443` of the `sql` container, which is mapped to the host.

#### Local access

Open a web browser and navigate to this address.

```
https://localhost:443
```

#### Remote access (using SSH)

If the simulator is running on a remote host, create an SSH tunnel from your local machine.

Shell

```
ssh -L 8443:localhost:443 <remote-host>
```

Then, enter the `https://localhost:8443` URL in your local browser.

> The simulator uses a self-signed certificate. Accept the browser security warning to proceed.

### 2 Log Into the Ocient Management UI

Log in using the default simulator credentials:

- **Username:** `admin@system`
- **Password:** `admin`

In the **Connect to** field, enter `system` to connect to the default administration database, or enter a specific database name such as `test`.

For details about the Management UI features and pages, see **Ocient Management UI Features**.

## Container Configuration

This section explains the configuration setup and options for the Ocient simulator.

### Ports

The container exposes additional ports that can be useful depending on the use case for the system.

| Exposed Port | Description |
|---|---|
| 443 | The Ocient Management UI (HTTPS). |
| 4050 | The JDBC port of the cluster. |
| 8080 | Ocient LAT service. When you load new data, the LAT client connects to this port. |
| 9090 and 9091 | The REST interfaces for the SQL and Foundation (LTS) Node processes, respectively. |

## Environment Variables

You can set these environment variables to affect certain aspects of the Ocient simulator.

| Environment variable | Description |
|---|---|
| LAT_MEMORY and LAT_MEMORY_DIRECT | Configures the memory used by LAT when it is running. For details about these environment variables, see the **LAT Service Configuration** page.<br>The LAT Node is the only node in the cluster affected by this variable. |

### Example

YAML

```yaml
services:
  lat:
    environment:
      LAT_MEMORY: '32G'
```

## Resource Limits (CPU, Memory, Disk Usage)

Docker supports a variety of options to limit container access to host resources. Refer to the Docker **Runtime options with Memory, CPUs, and GPUs** page for the full list of options. This section explains how constraints on specific host resources affect the Ocient simulator.

In all of these code examples, replace `IMAGE` with the filename of your Docker image.

The Ocient System applies Docker resource configuration changes individually on each of the nodes in the `docker-compose.yml` file (such as `sql`, `foundation`, `loader`, `lat`).

### CPU

CPU can be safely limited without adverse effects. Most workloads benefit from having multiple CPU cores available (four or more).

For example, to add CPU limits to the `sql` node, add this text to the `docker-compose.yml` file in the simulator package. Replace the `'4'` with the CPU limit that you want.

YAML

```yaml
services:
  sql:
    image: IMAGE
    deploy:
      resources:
        limits:
          cpus: '4'
```

### Memory (RAM)

The Ocient simulator requires sufficient RAM to execute all workloads. The system can be unstable in low or out-of-memory conditions. If you need to limit the memory of the running Docker container, it is recommended to benchmark the container memory usage on your workload and provide at least 1GB of RAM above the maximum observed.

> ⚠ When limiting memory of the Ocient Simulator, do not use the `--oom-kill-disable` option, otherwise the database can become unresponsive for a significant period of time after running out of memory.

To add memory limits to the `sql` node, add this text to the `docker-compose.yml` file in the simulator package. Replace the `8g` with the memory limit that you want.

YAML

```yaml
services:
  sql:
    image: IMAGE
    deploy:
      resources:
        limits:
          memory: 8g
```

### Disk Usage

When running the simulator without mounted data, you can specify the size in bytes of the data files created. The data files must be large enough to fit any data sets that you load. The file size defaults to 2GiB.

To specify a different file size, you can configure the rolehostd startup command in the `docker-compose.yml` file. Add the command option `loopbackDeviceSize` with a new value to configure a new file size.

In this example, the file size on the `foundation0` node is configured to 16GiB.

YAML

```yaml
services:
  sql:
    image: IMAGE
    command: "--bootstrap '{adminHost: \"sql\", ipAddress: \"foundation0\", loopbac
```

If you want to specify a new file size value, you must do it before you create your cluster.

While you cannot resize files on a running cluster, you can change this value by deleting and recreating your cluster. This process is irreversible and erases any existing databases and tables.

To resize file on an existing cluster:

1. Stop your cluster by running `docker compose down`.
2. Clear the `volumes` directory by running `rm -rf volumes/`.
3. If you have not yet edited the `docker-compose.yml` file, edit the file to include new `loopbackDeviceSize` values.
4. Restart your cluster by running `docker compose up -d`.

## Simulator Logging

The Ocient simulator sends all logs to stdout and stderr as well as any logging driver configured for the host Docker installation or the container. This logging allows for easy inspection of container logs using the `docker logs` command.

For details on logging with Docker, consult the **logging section** in the Docker documentation.

### Setting Logging Levels

You can modify the logging level for each node in the cluster by configuring the `rolehostd` startup command in the `docker-compose.yml` file. Add the command option `logLevel` with a new log level.

Supported values include `error`, `info`, `warn`, `verbose`, or `debug`. Defaults to `info`.

For details, see **Log Monitoring**.

### Example

YAML

```yaml
services:
  sql:
    image: IMAGE
    command: "--bootstrap '{adminHost: \"sql\", ipAddress: \"foundation0\", logLeve
```

## Other Logging Configurations

You can customize your logging configuration for each node by making changes to the `docker-compose.yml` file. In this example, the `sql` node has special configurations for its `max-size` and `max-file` values, meaning the container should have no more than five log files of 10MB in size.

### Example

YAML

```yaml
services:
  sql:
    image: IMAGE
    logging:
      driver: json-file
      options:
        max-size: 10m
        max-file: 5
```

Use `docker logs` to retrieve the logs. In this example, the `--tail` option limits the output to include only the last 10 lines of logs.

For more options, see the **docker compose logs** page.

# Ocient Architecture

Architecture of the Ocient System, including compute-adjacent storage, distributed query execution, and analytics components at scale.

The OcientAIQ™ Unified Data Platform is a modern, scalable distributed system capable of enabling complex OLAP-style analysis on the world's largest structured and semi-structured data sets using SQL. It features a purpose-built storage and an input and output layer designed for highly parallel interaction with modern NVMe SSD drives in a Compute Adjacent Storage Architecture® (CASA) that leverages erasure coding for cost-efficient reliability.

On top of this is a fully integrated execution engine and optimizer that were each built from scratch using modern design principles in a manner that deeply integrates with the storage and I/O layer. The result is a state-of-the-art data warehouse that can deliver outstanding, and even unprecedented, analytical capability on data sets with record sets numbering in the trillions, quadrillions, and beyond.

This section includes these topics:

- **Core Elements of an Ocient System**
- **Compute-Adjacent Input and Output on Large Working Sets**
- **Query Performance Optimizations**
- **Plan Optimization**
- **Exabyte Scalability Design**

# Core Elements of an Ocient System

Explore the core elements of an Ocient System, including SQL Nodes, Foundation Nodes, Loader Nodes, storage clusters, and the global metadata services.

An Ocient® System combines distributed nodes, high-speed networking, and columnar storage into a single platform for large-scale data analytics. Learn about the core elements of the system: the nodes that store, load, and query data; the network flows that connect nodes; the databases, tables, and views that organize your data; and the storage concepts, such as segments and erasure coding, that protect the system from hardware failure. Also, learn how you and AI agents connect to the system to execute SQL statements.

## Ocient MCP Server

The Model Context Protocol (MCP) is an open standard that gives AI agents a consistent way to discover and invoke tools. The Ocient MCP Server implements this standard for the Ocient System. Using the Ocient MCP Server, AI agents, and AI-powered code editors can explore schemas and tables, execute SQL statements, and invoke custom tools that you define in the database using SQL.

Ocient distributes the MCP server as the Python® package `ocientmcp`. The package works with any client that implements the MCP specification, and the server supports both local Stdio and remote Streamable HTTP deployments. The server itself defines only the `execute_statement` tool, which executes an arbitrary SQL statement against the connected Ocient System. The server discovers all other tools, including the system tools that ship with the Ocient System, by querying the `sys.mcp_tools` system catalog table. New user-defined tools that you create with the `CREATE MCP TOOL` SQL statement become available to MCP clients immediately, without a server upgrade or restart.

The Ocient System governs all MCP tools with standard access control privileges, and SQL statements that AI agents submit execute with the privileges of the connected database user. For deployment models, authentication, and the complete tool reference, see **Ocient MCP Server**.

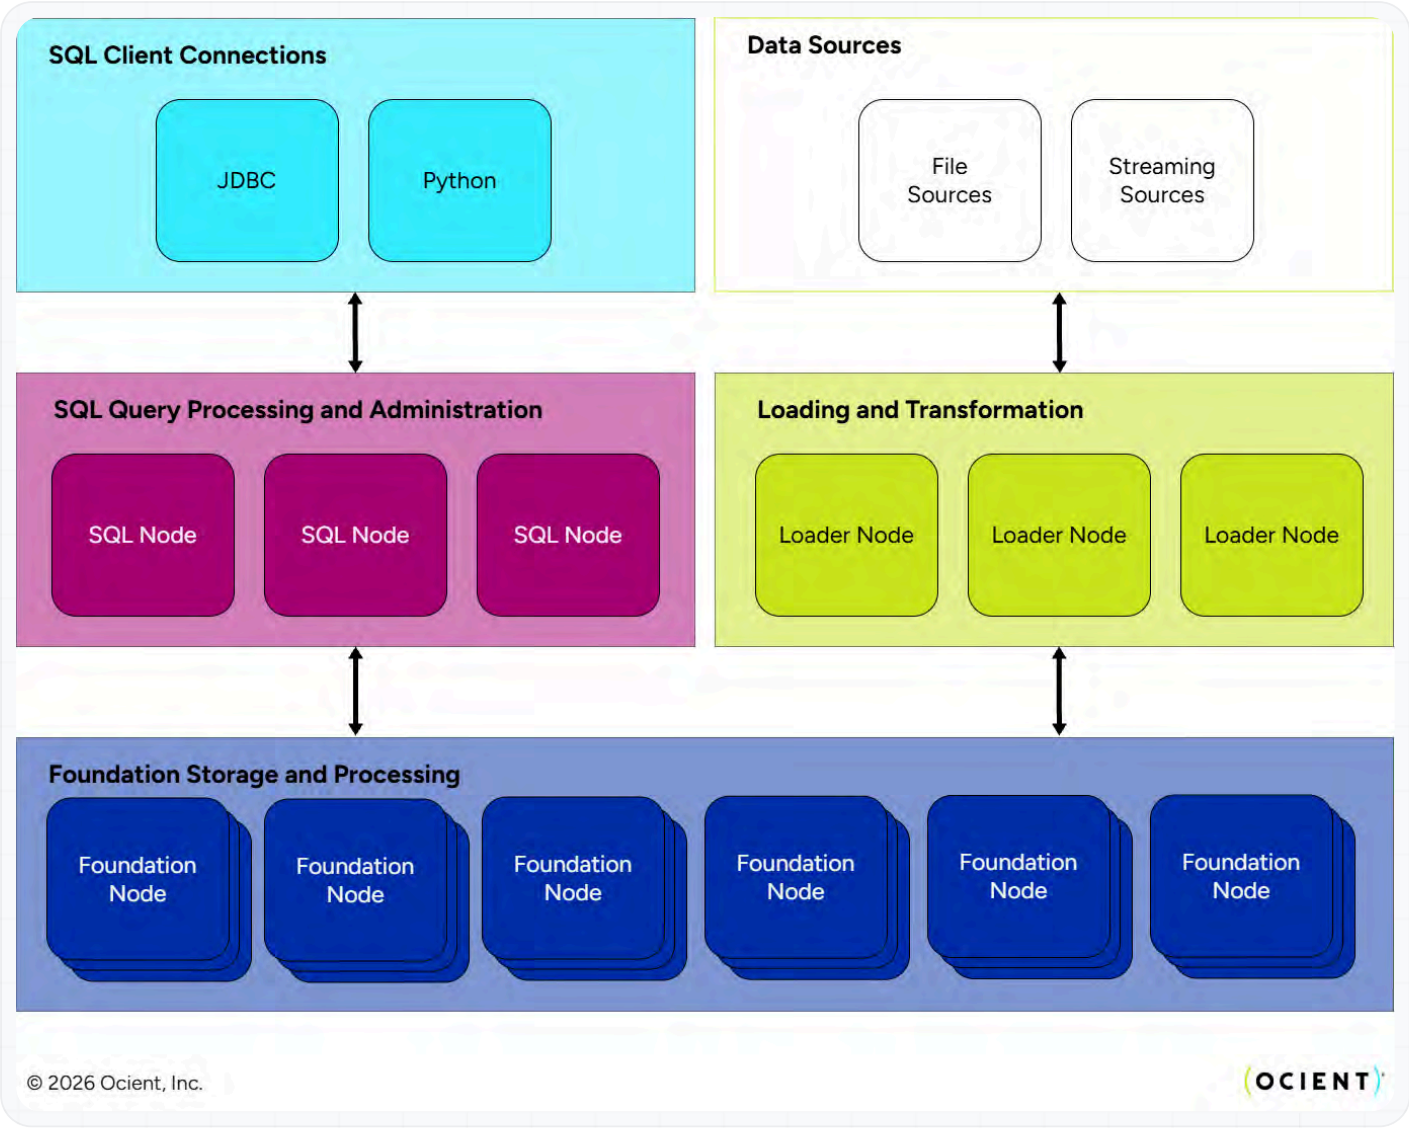
# The System and Nodes



The Ocient System is the collection of all the nodes within a single environment. This architecture diagram is an example of one Ocient System. Across systems, the number of nodes can vary along with the total storage capacity. Within a single system, users can define varying numbers of databases, storage groups, users, etc.

An Ocient System is made up of a collection of distributed nodes which each play a predefined role in the data warehouse. The different roles are generally responsible for storing and analyzing data, administration, and moving data into Ocient. These nodes are connected to each other through a high-speed 100 Gbps network connection. In addition to storing user data, the data warehouse also stores metadata about the system and data for its own internal operation and recovery. This collection of nodes, their data, and the interconnection between them make up the Ocient System.

The end user, analyzing data in Ocient, connects to this system through a JDBC or a Python-based client. AI agents connect through the Ocient MCP Server, which enables them to execute SQL statements and invoke custom tools that you define using SQL. From there, they interact with the database objects, such as tables and views. The architecture itself is abstracted from users, allowing them to focus on SQL queries and results.

While the number of nodes in an environment might vary, the inclusion of and purpose of the different roles do not. The following sections briefly describe the components in the architecture.

# Node Types

## SQL Nodes

A SQL Node is responsible for receiving incoming SQL requests and parsing the statements. This node also serves as the interface for System Administrators and Database Administrators to configure and maintain an Ocient System. Administrators can connect to a SQL Node using the Ocient command-line interface or their chosen client. SQL Nodes also host the **Ocient Management UI**, a web-based interface for monitoring system health, managing queries and pipelines, and running SQL directly in the browser.

When a SQL Node receives a query, it creates a plan for it using one of two optimization methods. After there is a plan for the query, the SQL Node distributes it to the Foundation Nodes. When the Foundation Nodes finish their processing, they return data back to the SQL Node for further processing and packaging the result set to the

client. When the result set is finalized, the SQL Node returns the data to the client. Beyond the Foundation Nodes, further processing is done on the SQL Nodes to process intermediate result sets delivered by the Foundation Nodes. Depending on the query, the SQL Node is responsible for a different proportion of the overall work of the query. Common processing done here are aggregations and joins that happen across the intermediate results delivered by the Foundation Nodes.

Administrators also use DDL or DCL statements to make changes to an Ocient System. When submitted to a SQL Node, the node executes the SQL statement across the system or forwards the SQL statement to the node assigned to execute it.

## Foundation Nodes

The Foundation Nodes store the user data in Ocient and perform the bulk of query processing.

A key architectural concept of Ocient is the Compute Adjacent Storage Architecture®, which collocates data and processing where possible. The Foundation Node is the central element of this architectural principle. When a query is deployed to the Foundation Node, it performs as much of the query as it can with the data on the node before having to join, aggregate, or compare it to other data. It returns that result up to the SQL Node for further processing, packaging, and returning to the user.

Foundation Nodes contain the majority of the storage in an Ocient System and are also typically the largest in number.

## Loader Nodes

Loader Nodes are responsible for extracting, transforming, indexing, and loading data ingested by Ocient from batch file sources as well as streaming data sources such as Apache® Kafka®. A user can specify the extraction source details and supply a transformation pipeline that manipulates the structured or semi-structured source data before loading it into relational form into Ocient tables.

Loader Nodes operate in a horizontal scale-out fashion allowing the loading system to scale to fit various ingestion requirements. Transparently to the end user, the Loader Node also manages exactly-once guarantees with data as it is loaded and converts pages into segments in the Foundation Nodes.

# Flows and Networking Between Nodes

Data and communication flows across the nodes of an Ocient System for a variety of different purposes. There are two networks that connect nodes, a 100 Gbps high speed network and a 10 Gbps network. These are used in different ways for data flows and administrative purposes.

## A Query in Ocient

When a user issues a query against the database, their SQL statement moves from the JDBC client to the SQL Node. The SQL Node parses and optimizes the query before handing the plan off to the Foundation Nodes. The Foundation Nodes do the first level of processing against the data before handing the results back to the SQL Node. The SQL Node further processes the data, constructs the results, and returns them to the client. When an AI agent executes a SQL statement or invokes an MCP tool through the Ocient MCP Server, the statement follows this same flow.

- The connection between the SQL Nodes and Foundation Nodes is typically a 100 Gbps network connection. The speed of the connection between the client and the SQL Node is subject to the speed of that network (outside Ocient).
- Every Foundation Node is connected to every SQL Node.

## Administration Flows

When administrators configure or make changes to an Ocient System, they do it using DDL and DCL using a SQL client. The SQL client relays the statement to a SQL Node, which parses it into commands that the Administrator Role on the SQL Node executes. This can impact the SQL Nodes, Foundation Nodes, or Loader Nodes, depending on the type of change or operation.

- The administration flow connections with the Ocient System are 10 Gbps connections.
- Every node is connected to the SQL Nodes that perform the Administrator Role.

## Loading Flow

When the load job is defined and started, the Loader Nodes read data from the source files, stage the data, process that data, and move the data into the Foundation Nodes.

Data pipelines enable you to define the data load and any corresponding transformations to ensure data is properly loaded.

- The network connections between the Loader and the Foundation Nodes are 100 Gbps.
- The Loader Nodes connect to every Foundation Node.

## Database, Tables, and Views

Similar to other databases, an OcientAIQ™ Unified Data Platform is a grouping of databases, schemas, tables, views, users, and data within one Ocient System. A single system can have multiple databases and schemas. Schemas define the structure of a database and contain the definition of tables, views, and indexes. While Ocient stores data on disk in columnar format, creating and working with tables in Ocient is like any other relational database. Ocient supports a wide variety of standard SQL data types along with an expanding set of geospatial data types. You can also create user-defined MCP tools with SQL statements, which package query logic into named tools that AI agents discover and invoke through the Ocient MCP Server.

Read more about:

- **Data Definition Language (DDL) Statement Reference**
- **Data Query Language (DQL) Statement Reference**
- **Functions Overview**

## TimeKey and Clustering Key

Each table in Ocient can contain a TimeKey® column that is specified when defining the table. The TimeKey column is used to partition the data within the Foundation Nodes. Time partitioning is an important performance mechanism used by the OcientAIQ Unified Data Platform. Because many, if not most, queries specify some time filter for the results, time partitioning allows Ocient to quickly skip data from irrelevant times.

When defining a table, users can also specify a clustering key containing one or more of the columns to further subdivide records on disk. This allows the database to quickly find records with the same key values.

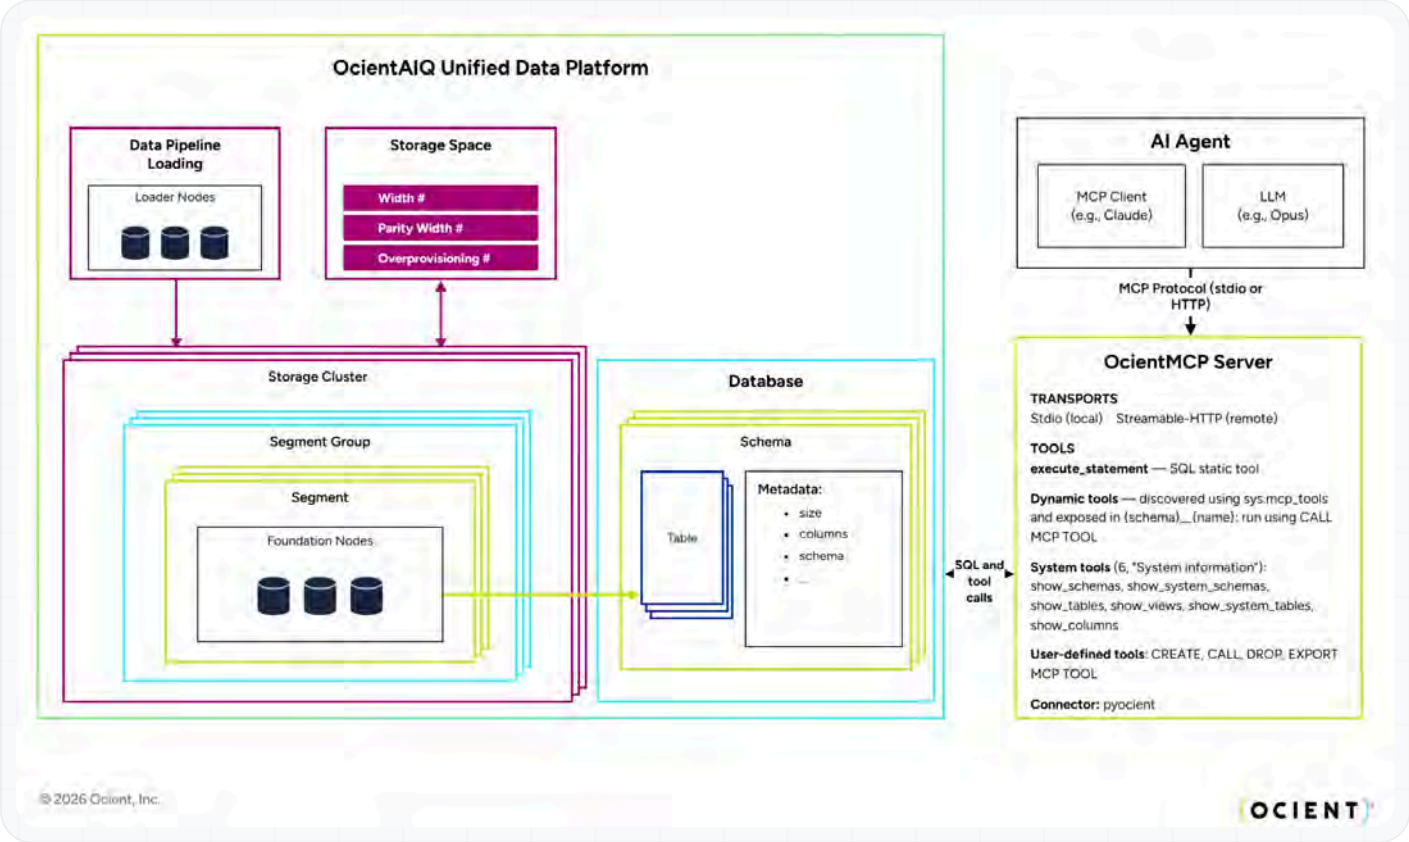
Read more in **TimeKeys and Clustering Keys**.

## Resilience to Hardware Failure

In order to provide reliability in the case of a hardware outage, Ocient uses erasure coding. Erasure coding is a mechanism to organize and compute parity blocks so that the system can rebuild missing data. This means that Ocient does not store redundant copies of the data for reliability. As a result, an Ocient System requires less overall storage than if it were storing one or more copies of the data for failover.

When a user defines their storage configuration, they specify the width of the group and the parity width. These values can vary based on how many Foundation Nodes are in the system and how resilient users want to make the Ocient System.

## Segments and Segment Groups



Segments in Ocient are storage units that contain rows and are divided into a fixed number of coding blocks with a defined size. Segments are typically sized on the order of gigabytes. You set the segment size when you define tables in Ocient. The size of the segment must be a multiple of the coding block size. The coding block is the unit of parity calculation and the smallest unit of recovery as well.

Multiple segments combine to form Segment Groups. A Segment Group has a fixed number of segments, named the width, which is the number of segments in the group. It also has a pre-defined number of parity blocks per set of data blocks for resiliency. Each segment has a defined index in the group. The Segment Group is physically stored in a storage cluster. Segment Groups can also be nested in directories named Segment Directory Groups.

When the user configures an Ocient System, they need to define at least one storage space and a storage cluster. A storage cluster is a set of Foundation Nodes that references a storage space. Multiple clusters can share the same storage space, but each cluster belongs to exactly one storage space. The nodes in a cluster coordinate together to store segment groups in a reliable manner. The storage cluster has a width, which is the number of nodes in the cluster. The width of the cluster and the Segment Groups stored on it must be the same. At the storage space level, the user defines the width and parity width of the space. Segments and their Segment Groups are stored

across these storage spaces and clusters. To learn more about erasure coding, see **Compute-Adjacent Input and Output on Large Working Sets**.

For details, see **Configure Storage Spaces**.

# Compute-Adjacent Input and Output on Large Working Sets

Ocient compute-adjacent storage architecture co-locates compute and NVMe storage to deliver high throughput on large working sets and analytic queries.

The storage of the data warehouse and the input and output (I/O) layer is built using a Compute Adjacent Storage Architecture® (CASA). When contrasted against modern cloud-based database engines, this means that the majority of the data to be analyzed is stored on NVMe SSDs directly attached to a significant fraction of the computational capacity of the system using the local PCIe busses of the nodes that make up the ***foundation level*** of the database engine.

This approach, which is similar to a traditional MPP architecture, is designed to capitalize on the performance characteristics of NVMe SSDs when executing queries against a large ***working set*** of data. It is important to note that when executing a query, a specific record could be included as part of the results, but I/O and computational effort must be undertaken to make that determination. A working set, therefore, is defined as the set of records stored in the database that are considered as part of query execution, even if those records are eventually filtered out or not returned. A “large” working set is one that is substantially larger, even by multiple orders of magnitude, than the available DRAM on the set of nodes performing the computations. When this is the case, ***remote-object*** database engines that store the majority of their data in a separate storage layer are substantially affected by their inability to keep all the potentially-addressed records near and accessible to computation at the same time. Depending on the query load and their exact engine design and scheduling, query execution times negatively suffer from both simple bottlenecks due to network link capacity and “cache thrashing” that produces expensive extra drive I/O.

Large working sets can be realized in two major ways:

1. Queries that regularly consider a substantial fraction of the entire data set. For example, regular querying or analysis of all data spanning years can mean a single query addresses most of the records in the database.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

2. A large number of smaller queries that all consider a disjoint subset of the whole data set. When these queries are executed in parallel the sum total of the disjoint sets of addressed records can also approach most of the records in the database.

The database engine in the Ocient® System is a world-class relational database engine that can go toe-to-toe with other modern engines on small working sets but won't necessarily out-perform them. After all, well known algorithms like sorting and hashing can only be made so fast when everything is in memory. But the performance distinctions of Ocient derive from its ability to scale CASA to keep all of the data close to the computation.

## NVMe SSDs in CASA

One of the biggest drivers for the development of the OcientAIQ™ Unified Data Platform was the ongoing shift from spinning HDDs to NVMe SSDs for data storage. SSD prices continue to fall, relative to HDDs, and there remains little doubt that they will eventually supplant HDDs for all but esoteric or extreme bulk storage applications.

To ride this storage wave, the Ocient engine has been built to minimize the cost of using these drives as the primary storage tier of the engine while maximizing their performance. There are two major aspects to cost management:

1. *Minimization of the total number of stored bytes needed to achieve reliable access to data in a performant manner*. This is achieved using a novel and tunable ***erasure coding*** scheme in conjunction with a variety of compression techniques. This is detailed more thoroughly in the following sections.
2. *Consideration for endurance management in I/O operations against the NVMe SSDs.* The Ocient storage and execution engine is designed to minimize the number of I/O write operations undertaken against the storage media in order to maximize its lifetime and reduce drive replacement rate due to endurance wear. At a high level, this usually means minimizing small or random writes to the drives and instead favoring larger and sequential ones. To achieve this, the storage layer uses a specially-written and database-aware file system underneath storage structures designed to capitalize on the large volume of low-mutability data being stored. Using these mechanisms, the storage layer is able to collate writes in a manner that produces relatively large (from the drive's point of view) ranges of contiguous blocks, ordered in the hundreds of KiB to hundreds of MiB in size.

© 2026 Ocient, Inc

# Erasure Coding

Of particular note in the storage and I/O layer of the OcientAIQ Unified Data Platform is the novel use of a tunable erasure coding scheme for data storage.

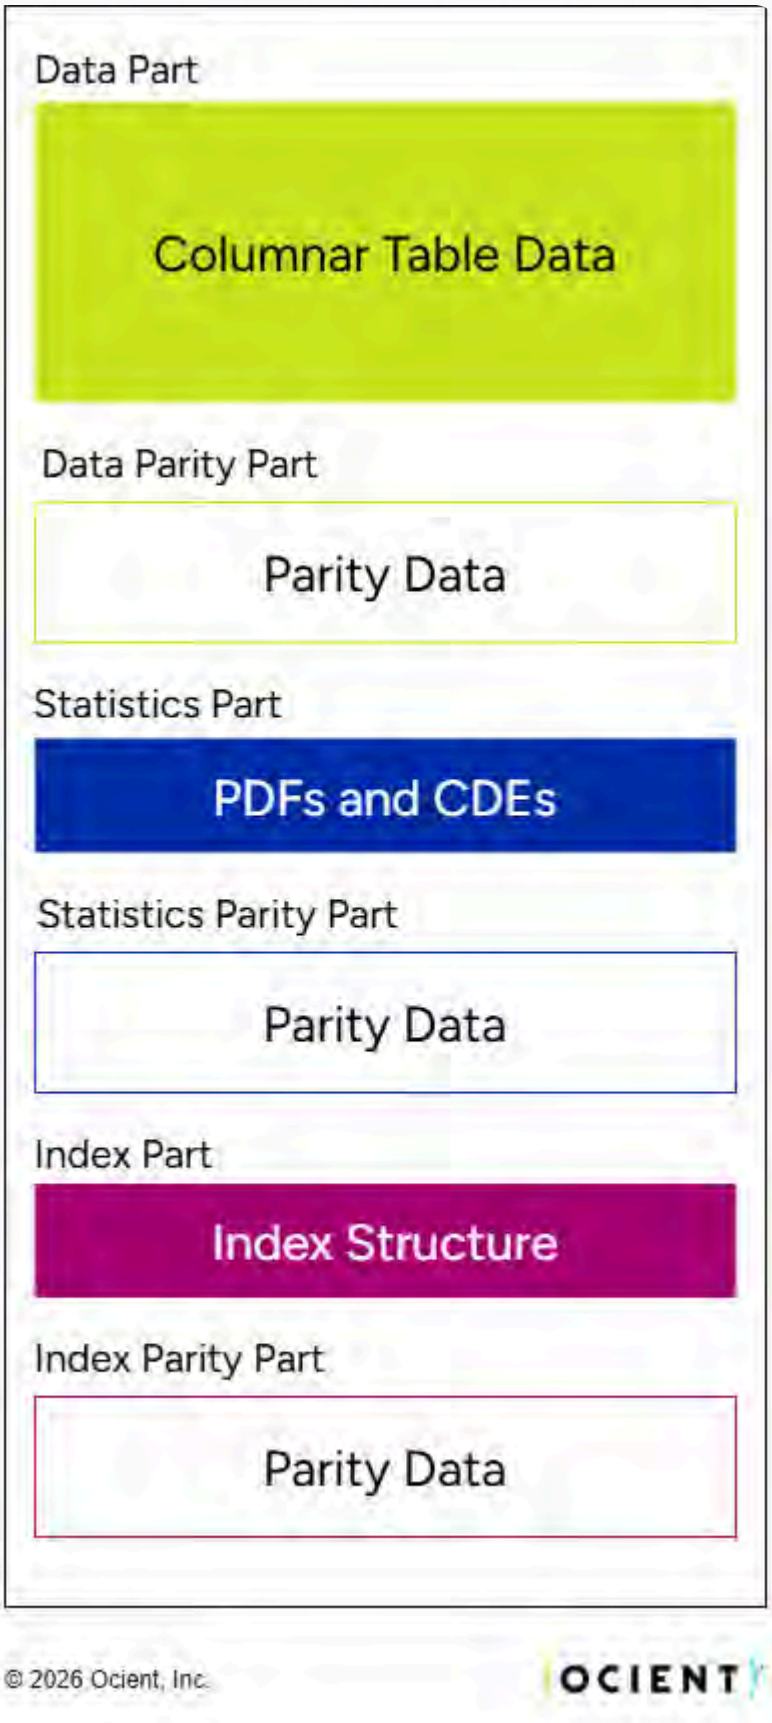
You can think of erasure coding as a generalization of simple XOR parity calculations. In a simple error correction scheme, you can apply the XOR operation on a sequence of bits: `B0, B1, B2, ..., Bn` such that: `B0 XOR B1 XOR ... XOR Bn = Bx`. An easily provable property of the XOR operation is that for any single Bi with 0 ≤ i ≤ n, that `B0 XOR ... XOR Bi-1 XOR Bi+1 XOR ... XOR Bn XOR Bx = Bi`. You can determine any single bit by performing the XOR operation on the other original bits and the extra bit together. In the context of error correction, this means that for the cost of an extra bit of storage (or memory) a system is able to detect, and even correct for, the loss of a single bit.

There are a variety of error correction schemes described in computer science and found in the industry. In the application of this concept to database storage, the Ocient storage layer extends it from individual bits, and beyond bytes, to an error correction unit of the 4KiB block (which is notably aligned with the I/O resolution of standard NVMe SSD drives). It also further extends from enabling single loss or failure to a fully tunable approach that uses ***XOR***, ***P+Q***, or ***Cauchy-Reed-Solomon*** coding that allows the user to specify exactly how many faults: one, two, or K, respectively. Like the simple XOR formulation, these schemes utilize mathematical computations (in this case, polynomials over a finite/Galois field) to compute additional blocks of data that enable reconstructing a configurable number of missing blocks.

In database and storage systems that utilize replication to provide data reliability and availability, it is common to describe storage in terms of the number of replicas (e.g., 3x replication allows for up to three failures). The obvious implication of replication is that each replica is a full copy of the original data and represents a multiple of the minimal data storage required. In an erasure coding scheme, the overhead for `K` tolerable faults is calculated as `(N + K)/N`, where `N` is the total width and `K` is parity width. If `N` is 10 (take that as a given for the moment) then to support a maximum of two faults (the equivalent of 3x replication, which includes the original data and two copies) the system needs only `12 / 10 = 1.2x` times the original storage size, contrasted with the 3x of the replication scheme.

© 2026 Ocient, Inc

The utilization of space-efficient erasure coding can be found in a variety of storage and transmission systems, but, in a classic space-time trade-off, the space savings come at a computational cost. The approach taken in the Ocient storage layer is novel, at least for databases, and is designed to mitigate the computational overhead of erasure coding.



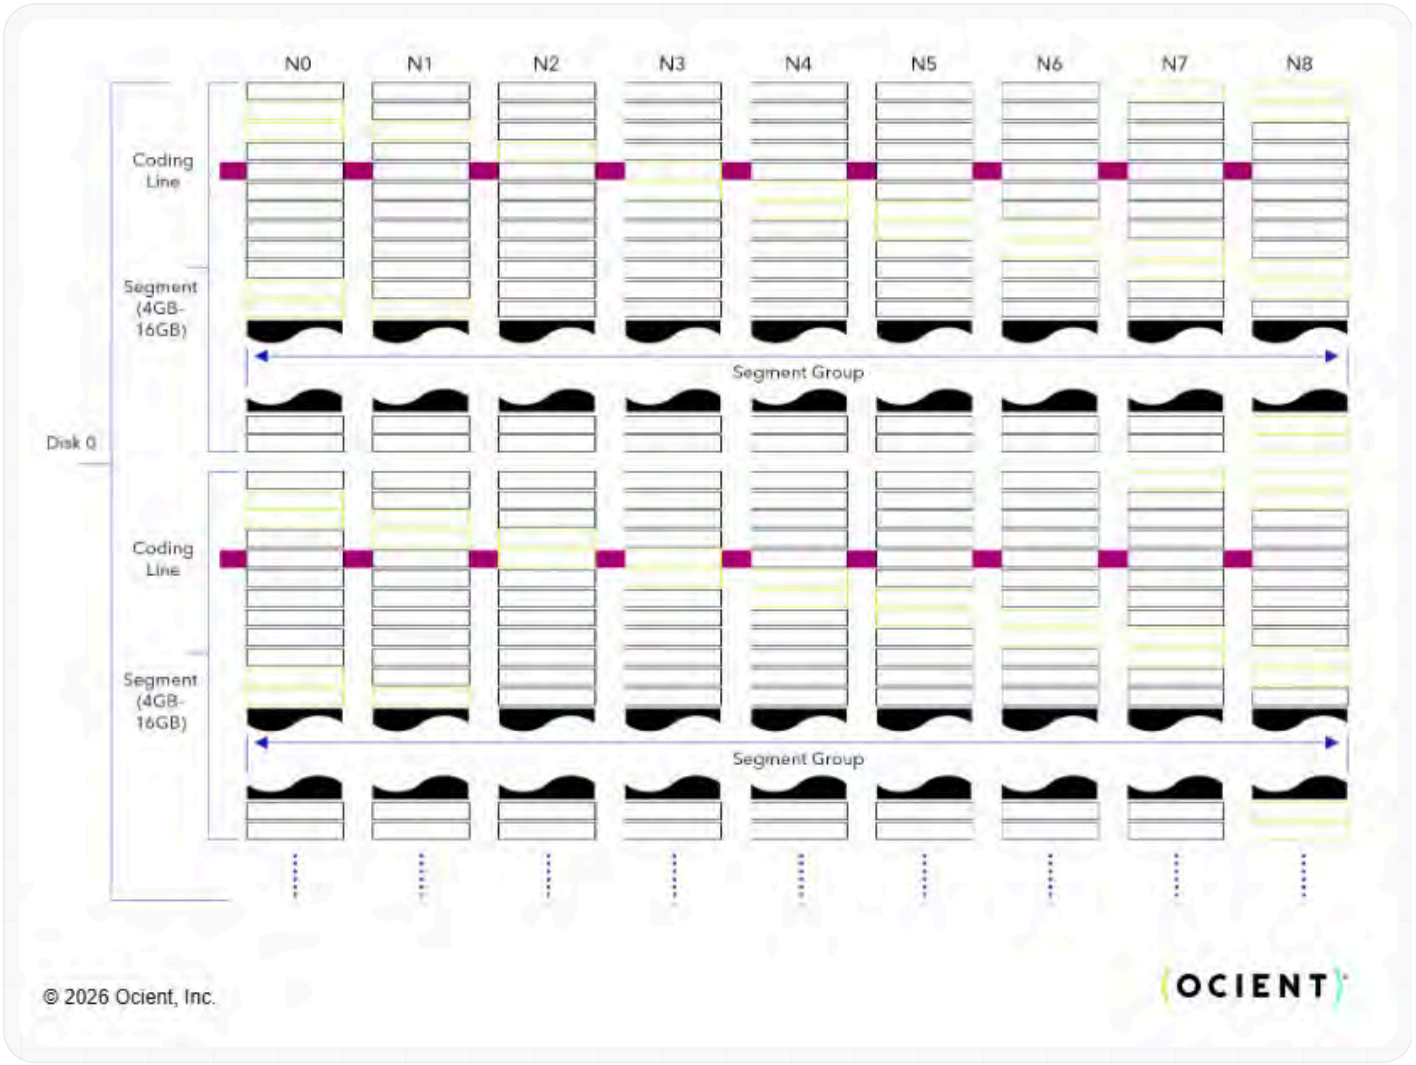
If one considers a “file” of some size as a unit of storage, a basic approach for applying an erasure coding scheme to provide loss tolerance to this file would be to break it into `N` chunks and perform the requisite computation to produce an additional `K` chunks. At read time, the system would select an available subset of the `N+K` chunks (possibly preferring the original `N`) and perform the **rebuild** computation to produce the original file for access. In this framing the unit of fault tolerance is the individual file, and rebuilding computational overhead can be found in the read path.

However, in a database designed for OLAP-style queries, the potential for the overhead of any rebuilding computation in the read path even when no drives or nodes are offline is troublesome. Additionally, when the system is in a degraded state, the potential need to rebuild an entire file only to retrieve a small subset of its data is expensive as well. The Ocient storage layer, by directly implementing the erasure coding scheme and integrating with it, avoids these issues in two major ways.

The first advantage is the unit of storage. Ocient uses storage units named ***segments***, which are not chunked into `N` pieces. Instead, `N` separate and similarly sized segments are considered together as a unit named a ***segment group***. The erasure coding scheme is then applied across the segments to produce `K` additional “segments” worth of redundancy information, which, in a very loose application of the term, is named ***parity data***.

This graphic shows a high-level illustration of how Ocient stores each data segment. Segments contain all the data needed for a subset of table rows, including the actual column data as well as indexes, metadata, and statistical data such as probability density functions (PDFs) and count distinct estimates (CDEs). In addition, the erasure coding scheme also includes parity data for other segments in the same segment group.

© 2026 Ocient, Inc



The newly generated parity data is then broken up and evenly distributed amongst the original segments (in a particular and calculated way) such that each segment is now approximately `(N+K)/N` times larger than it originally was, and any missing segment from a particular segment group can be reconstructed when one has access to any set

of `N` segments from the same group. The Ocient storage layer ensures that each segment from a group is stored on a separate physical node, thereby providing data availability in the event of up to `K` node losses.

Another important feature of this scheme is due to the fact that a given record is always stored in a single segment. Because the segments themselves are not chunked, any specified record is guaranteed to exist intact on some node/drive, and readable with no overhead incurred when that drive is online. Put another way, in the non-degraded state, the reliability scheme implemented incurs no computational cost.

The second advantage of the Ocient System is each segment acts as a self-contained unit of information, containing not only database records but also metadata and indexes on those records. These sub-units within the segment, named ***segment parts*** are individually addressable and independently rebuildable with 4KiB resolution. The implication of this is that in a degraded state (where a node or drive is missing), it is not strictly necessary to rebuild all missing segments to service a specified query. Instead, the storage layer is capable of addressing and rebuilding only the parts and even single blocks of parts required for it. This often greatly reduces the overhead and performance impact of a degraded state.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Choice of “N”

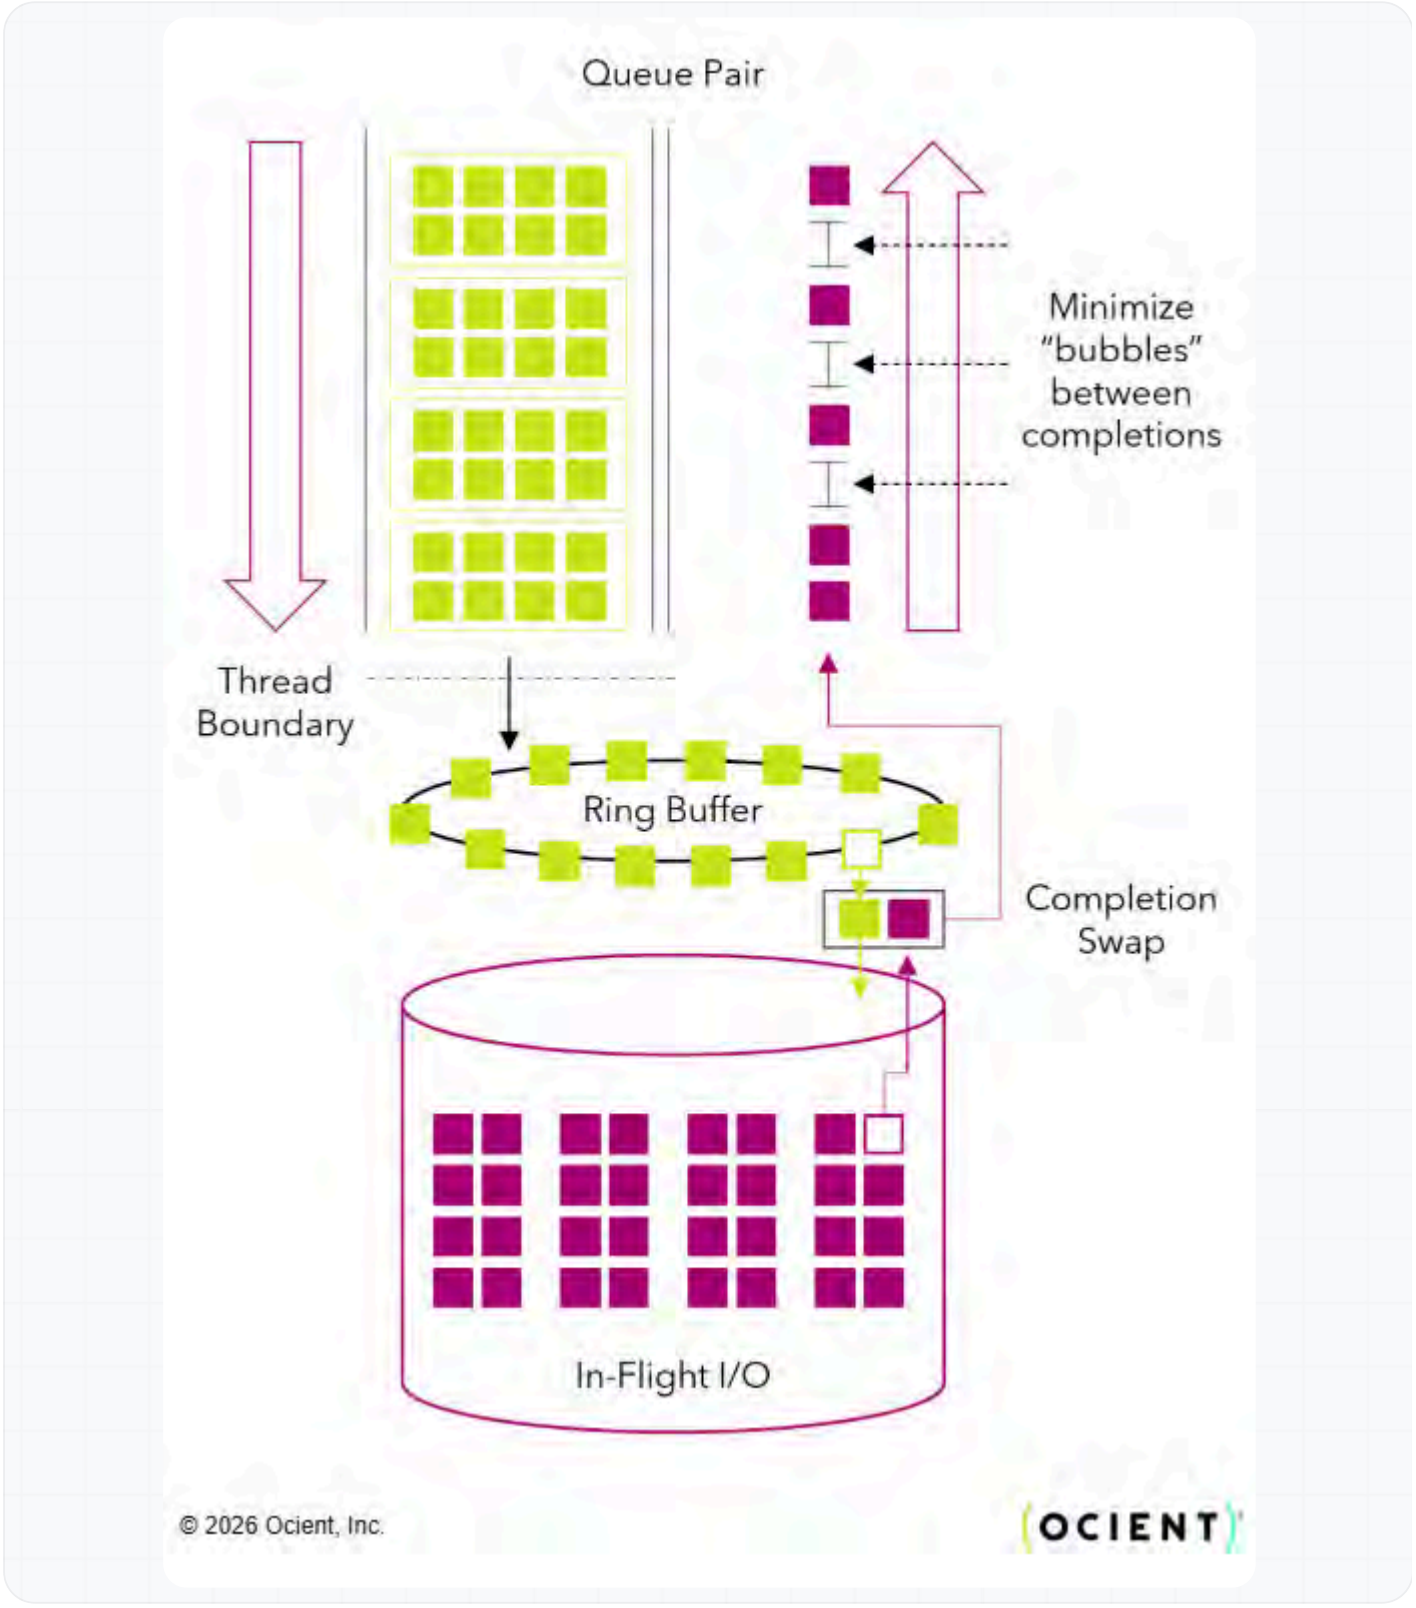
Earlier, it was taken as a given that `N` is equal to 10. The exact choice of this value is somewhat arbitrary but is generally bounded by system-level consensus constraints as well as the calculated cost of the network transit during rebuild operations. As `N` increases, the storage overhead for the data reliability for some specified `K` *decreases* because `(N+K)/N` approaches 1. However, the total amount of information that must be considered and moved over the network for, as well as the actual computational cost of, a rebuild *increases*. Real-world usage has found that an `N` somewhere between 8 and 12 provides a good tradeoff between these two opposing considerations.

## NVMe Userspace Optimizations

A final important aspect of the Ocient storage and I/O layer is the database engine’s direct interaction with the SSDs storing segments. The term “direct” in this context can

be contrasted with how a more standard approach might look. In many database systems, record storage is achieved using a set of files stored on a disk in some file system (such as EXT4, NTFS, or ZFS). And generally speaking, kernel-provided system invocations or services, like `read()`, `write()`, and `mmap()`, perform reading and writing of those files. Obviously, this is a fine approach in general, but when performance is of utmost importance, the overhead of the system calls, memory copies to and from kernel memory, as well as the implementation of the underlying file systems, all have detrimental and sometimes unpredictable effects. For example, it is well known that the kernel of Linux® EXT4 implementation takes global locks during certain metadata operations, which can have a significant detrimental effect on parallelism and throughput.

Some databases eschew standard files and perform some form of I/O directly against kernel block devices in order to avoid file system overhead. This is surely an improvement, but the kernel's block scheduler, extra memory copies to/from kernel memory, and the overhead of system calls still exist.



In order to overcome these performance impacts, the Ocient storage layer directly interacts with the NVMe SSDs that store segments in two important ways:

1. Each NVMe drive is decoupled from the standard Linux block device driver and instead attached to a device driver that enables low-level interaction with the device using the PCIe protocol. The implications of this approach are that the storage layer and database engine can directly communicate the NVMe protocol to the devices *and* do so using user memory. This completely eliminates all system calls and memory copies required to do I/O with the NVMe drives. The database provides direct pointers to its own virtual memory for I/O operations, and the drives directly write and read to and from that memory.

   An interesting result from this approach is that the Ocient storage layer and engine were entirely unaffected by the Linux kernel's mitigations for the Spectre and Meltdown classes of attacks. This is because the primary mechanism of the mitigation resulted in a substantial increase in the overhead of the user-to-kernel transition associated with system calls. Other database engines with more standard approaches saw, in many cases, appreciable performance degradation.

2. Modern NVMe SSDs are capable of a million 4KiB random reads per second. This is strikingly and substantially more than HDDs (where even the best drives can

produce only hundreds). However, for most economical SSDs, these rates can only be achieved when large numbers of parallel in-flight requests are maintained over a substantial fraction of the drive's address space. The Ocient storage layer implementation, in conjunction with specially tailored data and metadata structures, not only promotes this parallelism to be evoked during query execution, but also is written to minimize "latency bubbles" by always having a replacement I/O operation teed up for a drive when it completes a previous one.

# Columnar Compression

As a column-oriented data warehouse, Ocient is able to leverage per-column data locality and similarity to achieve excellent data compression.

- For fixed-length columns, a combination of delta-delta compression, run-length encoding, and NULL elimination provides significant storage reduction for many data types.
- For variable-length columns, the Ocient System can apply per-row compression to reduce the size of large values.
- Both fixed and variable-length columns can benefit from whole-column compression using a shared dictionary trained on a per-column and per-segment basis.

Column compression works best when combined with secondary indexes on frequently filtered columns.

# Query Performance Optimizations

Tune query performance in Ocient using indexing, clustering keys, time keys, statistics, materialization, and workload-aware query design patterns.

## Specialized Indexes

The storage engine, execution engine, and optimizer are all aware of two special concepts that can bring about significant query performance benefits. Neither of these specializations are strictly required in any table or query, but the Ocient® engine capitalizes on the fact that for the data sets with trillions or quadrillions of records they are often advantageous.

### Time Keys

Much of the data in hyperscale databases is produced by machines, devices, loggers, and sensors. The records these entities emit often have a temporal nature: they are timestamped or otherwise sequenced relative to each other. At query time, it is often the case that queries themselves have temporal predicates (e.g., “select all records for this user *for this year*”) as well.

When these two conditions are met, the storage layer, execution engine, optimizer, and loading infrastructure all have special handling built-in for more efficiently processing these records. The time-based processing of records shares similarities with zone maps in that they can be used to avoid input and output (I/O) for non-intersecting sets of data when predicates against certain columns are present in a query. However, the specific temporal nature of the data is further utilized to make loading more efficient and also impacts segment grouping and data roll off.

### Clustering Keys

For many data sets, there is often a commonly queried set of columns that form the basis for a variety of analytical tasks. For example, in a network security database recording metadata of IP traffic, it might be the case that a substantial fraction of interesting queries are concerned with the public destination IP address, represented as a column in a record, in addition to other constraints or filters.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

When this is true for a subset of the columns in a given table, a ***clustering key*** can be defined, which enables additional specialized handling across the storage layer, execution engine, optimizer, and loading infrastructure. A clustering key shares some similarities with the “partitioning key” concept found in other databases in that it is defined in terms of one or more columns in the table and also factors into locality decisions for storage. However, unlike most systems, the clustering key *is not* a strict partitioning, and is instead only a ”hint” that promotes locality for storage to improve I/O efficiency for queries that locate records using it. Because it is only a (usually followed) hint, the storage layer and engine do not suffer from issues related to partitions outsizing others or forced locating of segments on particular nodes.

### Global Dictionary Compression

Global Dictionary Compression, or ***GDC***, benefits both storage utilization and query throughput for columns with low cardinality (≤ ~1 million distinct values). When enabled for a specified column, that column’s values are mapped to a succinct global enumeration that is stored on disk and used at query time. GDC is often enabled for variable-length columns representing an enumerated set of potential values (e.g., city, county, and country names, or classification tags). In these scenarios, it provides significant compression and also enables a number of optimizations in query and join processing. In this latter category, the optimizer is able to delay or even eliminate the decompression step during execution because there exists a single global key-to-value mapping. This often results in a significant reduction in string data processing as well as network and memory bandwidth.

Like other forms of compression, GDC is completely transparent to end users. New values are added to the global enumeration automatically, and compressed values are mapped back to their original value in query results.

## Specialized Types

### Complex Types: Tuples, Arrays, matrices

In many analytical workloads, semi-structured and multi-dimensional data must be analyzed. Ocient offers complex data types to efficiently store and analyze this type of information, in many cases dramatically reducing query response times when compared to normalized schema designs. Each complex type allows groupings of

elements to be stored and analyzed in a denormalized fashion with the parent record, and combinations of these complex types might also be used. This avoids the repetitive joins across billions of records required for nested data in a normalized schema improving query response times. Finally, Ocient's indexing strategies extend to complex types as described here.

The complex types supported in Ocient include Arrays, Matrices, and Tuples. An array is an ordered list of elements. The element can have any data type including a tuple. Array types provide operators for efficient set operations and standard SQL semantics like SOME and ALL. matrices are multi-dimensional arrays that share many of the same benefits as Arrays when denormalizing schemas or working with matrix data for mathematical operations.

Tuples are structured objects in a single column created from individual data elements of the same or different underlying types. Arrays of Tuples provide the ability to denormalize structured elements that can then be jointly queried and indexed for improved performance in some cases. Because the array of elements can be stored in a columnar fashion and associated with the parent row, they need not be joined to the parent table repeatedly to query them. Performance is improved, and working set memory consumption is reduced on queries that would otherwise need to join tens of billions of rows to potentially trillions of rows. The flexibility of these composable complex types creates more options for database administrators to structure data and optimize performance at scale.

## Secondary Indexes

A variety of secondary index types are used to improve query performance. Secondary indexes are built and searched on a per-segment basis, allowing different segments of a specified table to be indexed differently where appropriate.

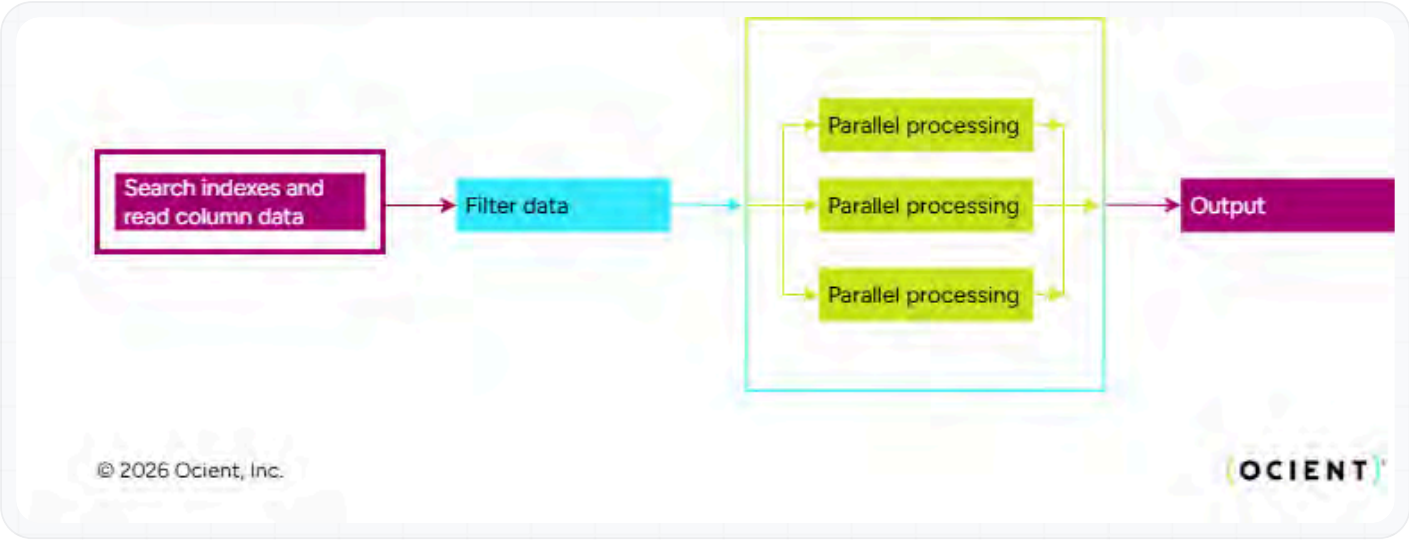
For fixed-length column types, an I/O-optimized inverted secondary index enables fast equality and range queries. Variable-length columns support hash and N-gram indexes that enable fast equality and `LIKE` filters, respectively.

Complex types like tuples and matrices are a concise way to model certain data sets. In order to support efficient filtering on these types and their sub-components, filters are pushed into the I/O layer and use secondary indexes when possible.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

You can create indexes on arrays of both fixed and variable-length elements to optimize contains, overlaps, and other similar operations. Additionally, `for_all()/for_some()` syntax allows other filters to be pushed down and applied to arrays using an index, without requiring `unnest`. In particular, `for_all/for_some(varchar_array_col) LIKE <filter>` utilizes N-gram indexes to optimize textual queries over arrays of strings.

## Per-Segment I/O Pipelines



The I/O layer is designed to minimize the amount of on-disk data read and processed for each query by compiling a custom ***I/O pipeline*** for each segment of data the query accesses. An I/O pipeline is a directed acyclic graph that represents an efficient I/O plan for the particular columns and filters of that query combined with indexes and data that can vary from segment to segment. This plan adjusts for data demographic changes over time, and for schema or index changes also. Just like the query plan itself, efficient pipelines are critical for performance.

A simple I/O pipeline example is illustrated here:

This graphic example shows the I/O process stages that go into action when the Ocient System compiles a pipeline. These stages are as follows:

1. When a query is in the IO pipeline, each segment first searches indexes to minimize the data that must be read and processed.
2. The indexes help to quickly filter the rows. When possible, filter predicates are pushed down and evaluated in-line, further reducing the number of rows needed to read, even when an appropriate index does not exist.
3. The system reads rows that pass the filters in parallel.
4. The system returns the query output.

© 2026 Ocient, Inc

During execution, ***I/O pipeline elements*** work together to search indexes, read column data, and apply filters to return the exact set of matching rows from each segment. Much like CPU instruction pipelining, the I/O pipeline attempts to mitigate latency while fully utilizing fast storage devices requiring deep I/O queues. The graph for a sophisticated query can orchestrate dozens of pipeline steps in series and in parallel. This layer works to keep disks saturated by coordinating I/O across segments with read-ahead and a shared priority queue.

A good I/O pipeline determines the set of cluster key and secondary indexes to use, and an optimal ordering based on index selectivity to filter rows at maximum speed. When possible, filter predicates are pushed down and evaluated in-line, enabling optimizations even when an appropriate index does not exist.

## Optimizing I/O with Bloom Filter and Index-Based Join Push-Down

A pair of advanced techniques are employed to dynamically reduce the amount of I/O needed when processing certain types of joins.

- **Index-based join push-down** — As a running query narrows the collection of potentially matching values, an updated list of filters can be dynamically pushed down into running I/O pipelines. When a matching index is present, the I/O layer can begin using it mid-query to reduce I/O. Otherwise, this technique has the same benefits of early filtering as a pushed-down Bloom filter.
- **Bloom filter push-down** — When one side of a join is fully determined, the execution engine can build a Bloom filter that gets pushed down into running I/O pipelines to enable early filtering of unneeded values at the lowest level. As a

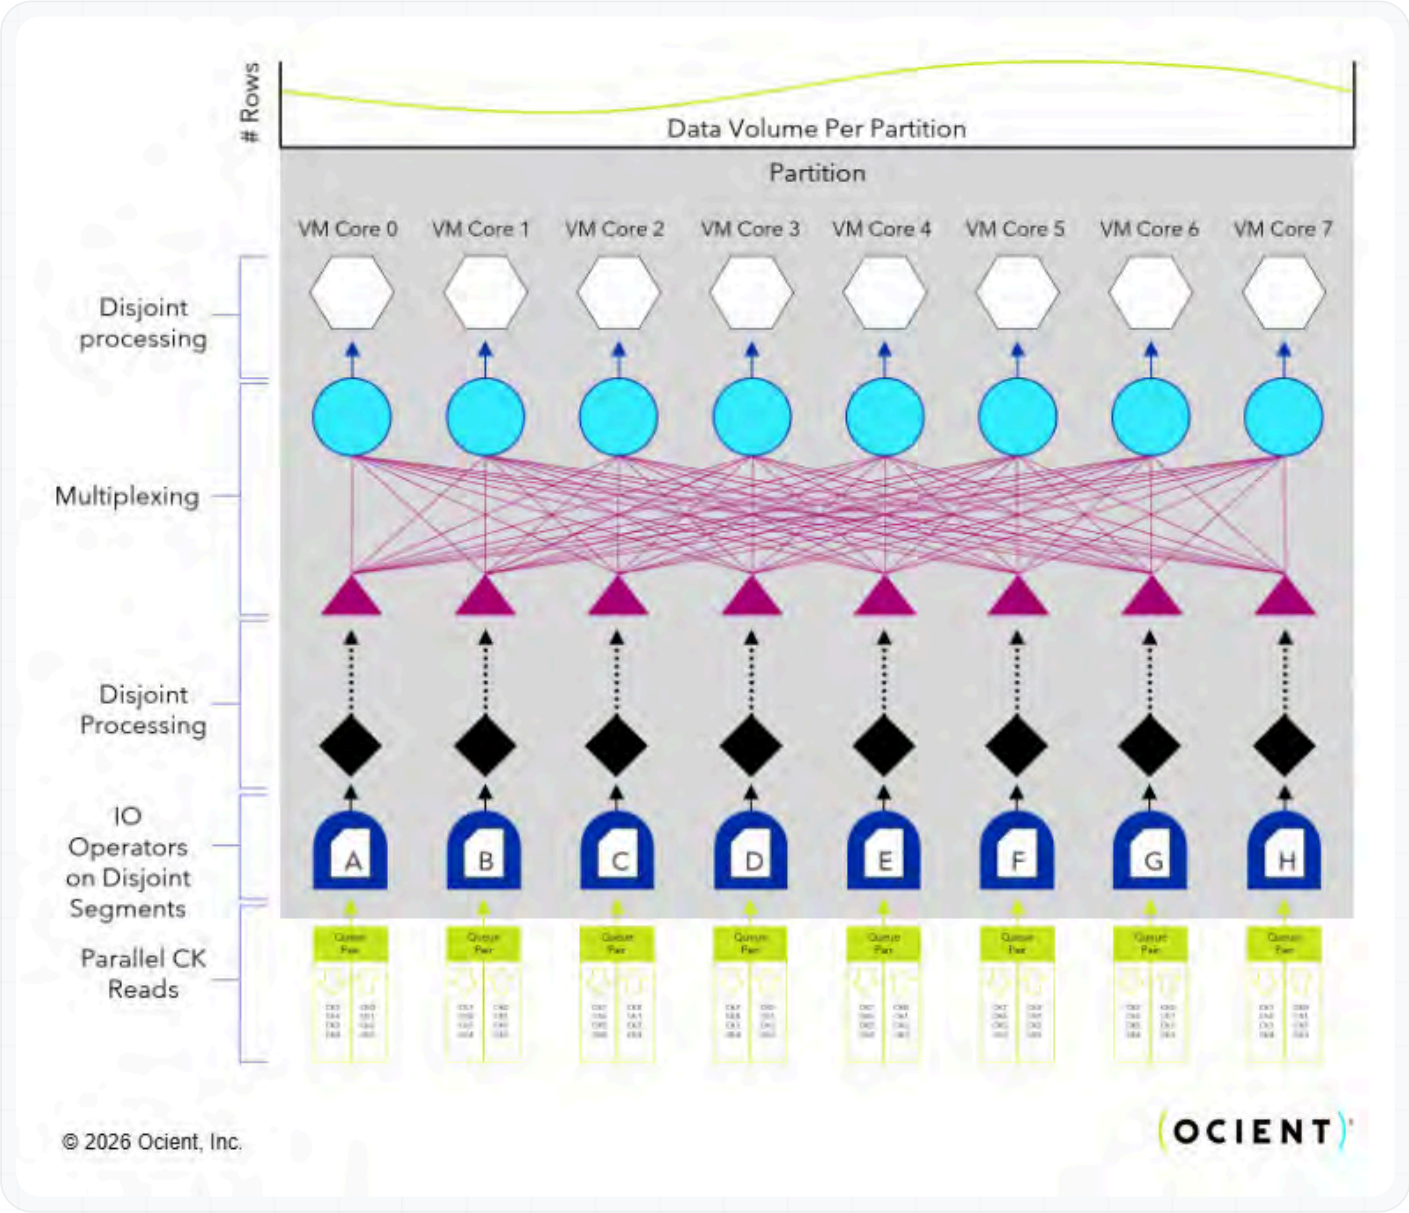
probabilistic data structure, Bloom filters can be tuned to provide filtering benefits for even high-cardinality sets.

Both of these techniques reduce I/O on dependent columns, memory, and storage bandwidth for unnecessary rows and unneeded join processing.

# Query Execution

## Parallelism

The storage layer and I/O access patterns to promote parallelism would be of limited impact if the data processing working on the actual data was not itself highly parallel. To that end, the execution engine (which is named the ***Virtual Machine or VM***) is designed to maintain parallel and disjoint flow of data during data processing.



A query ***plan*** is a (mostly) directed graph of **plan *operators*** in a tree-like arrangement. At the leaves of the tree are the raw I/O operations undertaken to bring records off of SSDs and into memory for processing. Internally, iterative processing, computation, filtering, and joining is undertaken by successive operators to produce the final results for the query. The execution engine is named the VM because it structures plan operators as assembly instructions (such as ADD and `MOV`) to be scheduled and executed.

The fundamental organizational unit of this execution engine follows a design pattern named ***resource-aligned parallelism*** where a series of independent execution units, strongly coupled with hardware resources like cores, memory, and disks, disjointly process independent ***data partitions*** of records that flow independently and in parallel within the engine. Because minimal to no data sharing is required across data partitions, the execution engine not only maximizes resource utilization and throughput, but also scales very well as CPUs continue to include larger numbers of cores.

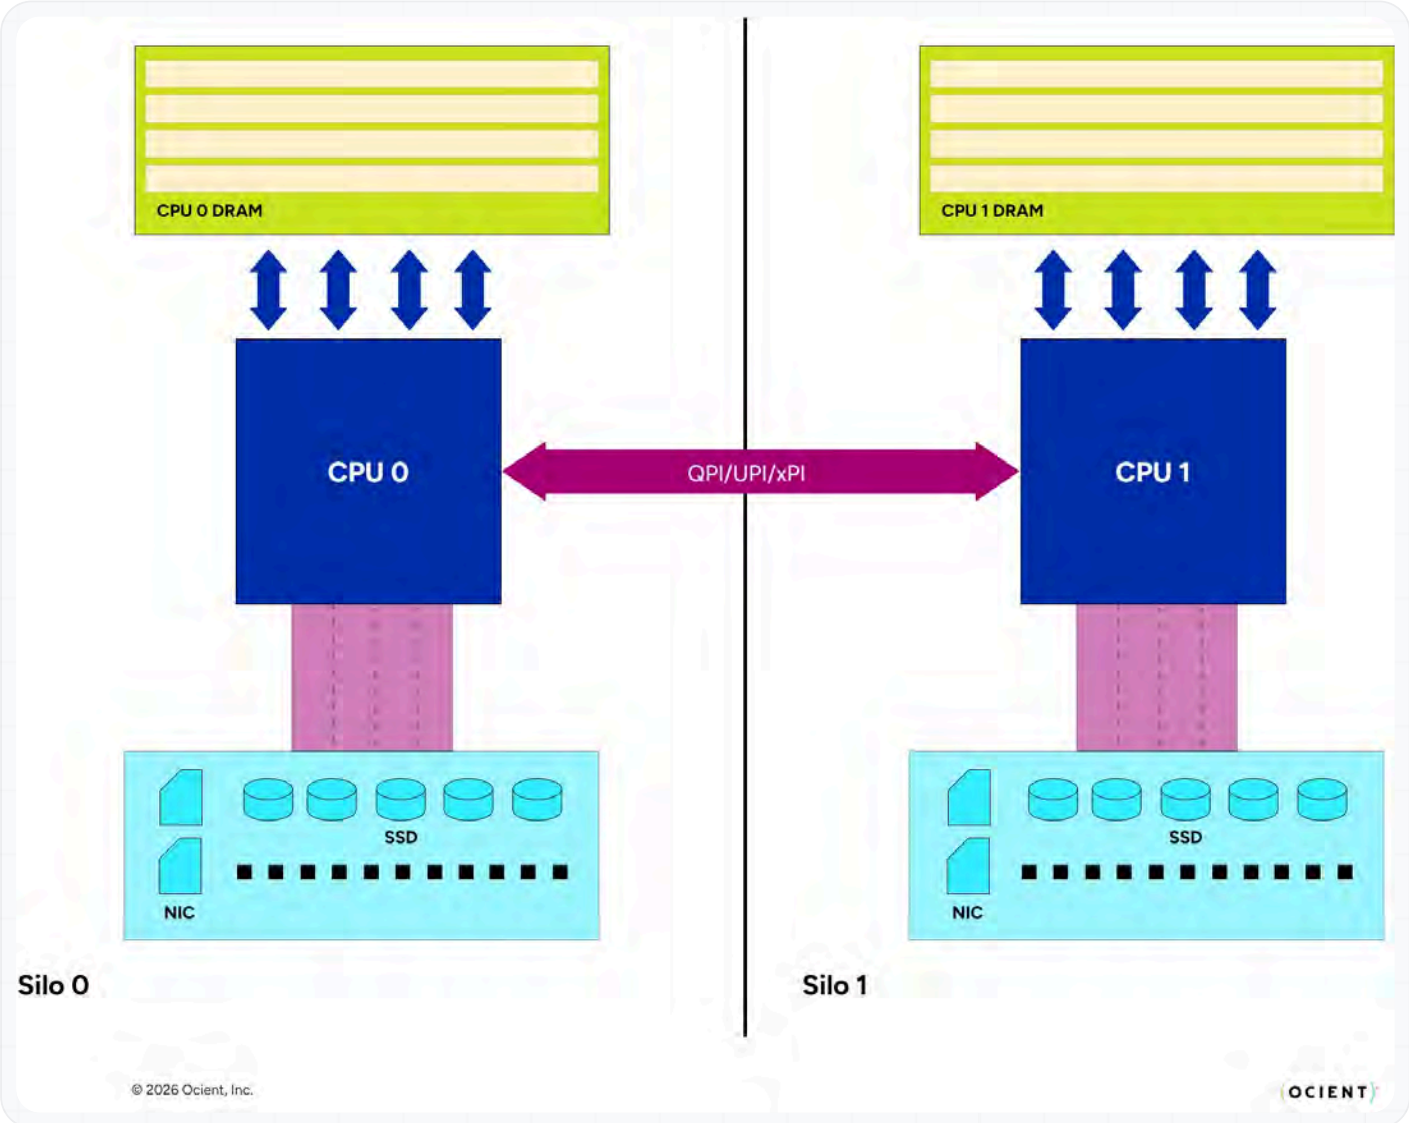
The number of data partitions across any edge within the plan tree is usually, but not always, equal to the number of distinct ***VM cores***. Each VM core is a dedicated and isolated CPU core that does not process any other database or system threads (this is achieved using a Linux® kernel feature named “cpu isolation”). Then, each plan operator is locally “compiled” into a number of ***operator instances*** that is equal to

the local number of VM cores. In this way, any individual operation within a plan can be spread over all allocated computational units to independently process the parallel disjoint subsets of records it is to handle.

Of particular note is the attention paid to data skew. In order to maximize aggregate throughput across all parallel operator instances, it is required that they perform approximately the same amount of work. If work is not evenly distributed across all parallel processors, then query execution is limited to the slowest one while the others have no work. Even partitioning of data is easy to achieve in some cases, and impossible in others (it depends on the operation and the data), but the Ocient engine undertakes a variety of special efforts to evenly balance data flow, even in non-trivial cases.

An interesting example of this is found in sort execution. If one were given a set of integers to sort, a straightforward approach to parallelize the sort operation would be

to split the set into a sequence of disjoint subsets `S0, S1, S2, ..., Sn` where for all `n`, the integers in `Sn` are all less than the integers in `Sn+1`. Then, one could sort each subset, in parallel, to end up with a totally ordered sequence of integers across all sub-sequences. Put another way, the system splits and groups the integers at boundary values on the number line, then sorts each interval independently. The problem of data skew arises when the number of rows per interval (or subset) is not roughly equivalent, with the worst case being where one interval has all the integers and the others all have none. The problem is one of boundary selection: any naive choice can be subject to skew. To address this in the sort case, the database engine, in conjunction with information provided by the optimizer based on metadata and statistics, *adjusts* the boundaries for the ranges such that each boundary has a roughly equivalent number of rows.



## Implementation Efficiency

When discussing parallelism, you might have noticed several terms that sound very operating-system-like: threads, disjoint cores, compilation, and so on. In fact, the database engine directly implements many general pieces of functionality that are usually in the domain of the operating system, but with database-specific features that outperform standard system-provided ones.

1. *Specialized hugepage-backed memory allocators*. Designed for high throughput and low lock contention, these allocators are backed by hugepage memory, not only deriving the benefits of fewer TLB misses, but also making them suitable for userspace I/O operations because their virtual to physical address mapping is fixed. Special efforts were made to make them extremely fast and efficient within the resource-aligned parallelism pattern.
2. *Cooperative per-VM-core Scheduler*. This component runs per VM core, allocating CPU time to operator instances on that core to process data. In this framing, each operator instance can be considered as a parallel thread on its core. However, the scheduler is not a generic thread scheduler, but instead has access and visibility into inter-operator data flow, concurrent query memory utilization, and workload management limits. This means that it has a much richer set of information with which to make intelligent scheduling decisions that promote maximal total system throughput.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

3. *NUMA-aware Data Processing*. Modern multi-socket systems utilize a non-uniform memory architecture (NUMA), whereby individual CPUs (and the cores in them) have both local memory and remote memory. The implication of this is that a particular memory access made against local memory by code executing on a core is not only lower latency than a remote one, but also avoids an expensive hop across a dedicated memory bus with a finite amount of bandwidth. Because most commodity CPU packages directly integrate a PCIe bus as well, it is the case that not only is there local and remote memory, but local and remote devices as well. To account for this, the VM groups locally-connected RAM, disks, and cores into a functional unit named a ***silo*** that for all practical purposes is treated as an isolated and independent processing unit. Generally speaking, records for a particular disk will be read only into local memory, and only processed on local cores, all within that silo. This avoids expensive cross-socket communication and greatly improves throughput.

# Plan Optimization

Optimize query execution plans in Ocient by reviewing EXPLAIN output, applying hints, tuning statistics, and adjusting workload settings for performance.

A foundational element of any high-performance database is its plan optimization engine. Recall that a ***query plan*** is in many ways similar to a generic computer program. A key distinction, however, is that its machine code is in the language of relational algebra, set operations, input or output (I/O), network, and other database primitives. When a database converts SQL queries into a query plan, it must always generate a plan that produces the correct query results.

An over-used joke at Ocient® is that if you could return incorrect results, you could make a blazingly fast database by simply returning random numbers for every query. By way of analogy, this correct result requirement is the same as saying that a C++ compiler must always produce x86 machine code that correctly executes the originally provided instructions. But just as a specified C++ program can have many different possible representations in x86 machine code (different compilers, optimizations, etc) it is also the case that a given SQL query can have many (infinitely, actually) different query plans.

In a database, the optimizer's job is to take an already-correct plan that is naively generated from a SQL statement and produce an alternative plan that will emit the same results. This is normally viewed as a minimization problem where the alternative plan is "less than" the original plan in some metric (usually estimated run time), and database engines have evolved extremely varied approaches to solving it. Some challenges to consider:

1. The search space for the minimization problem is infinite. This means that any algorithm must eventually converge to some answer but do so in a reasonable amount of time. It should not take 100 seconds to shave 1 second off of a 2-second query.
2. Plans are compared to each other based on some metric like execution time, but this metric is not trivial to build. Having a metric function `M(p)` that returns a useful number and is cheap enough to compute is a challenge in and of itself.

© 2026 Ocient, Inc

Adding to this challenge is the additional considerations beyond measuring the computational cost of plan execution, namely disk and network I/O costs as well.

For these challenges, most database engines incorporate some sort of statistical approach. Statistics on the tables being queried (calculated either at data load time, or periodically updated) are used to bound execution and I/O estimates. The optimizer of the Ocient System does this as well. While basic statistics like row counts are certainly considered, more advanced mathematical approaches are used as well:

1. *Multi-dimensional probability density functions*. If a table has `j` columns, then it can make use of a `j` dimensional "table space" function `f(v0, v1, v2, ..., vj)` that maps a particular set of column values to the probability of those values. The Ocient System can then compute approximate row counts in the table by taking integrals of `f` in some hyper region of the table space.
2. *HyperLogLog*. In addition to row counts, the ability to estimate the number of *distinct* values is important as well. The basic idea behind HyperLogLog is that if a set has a uniformly randomized set of values, and `n` is the maximum number of leading zeros in the binary representations of all values in the set, then a good estimate of the set's cardinality is `2^n`. Here, each column is considered a set, and this statistical approach can estimate the number of distinct values for each column.

With such mathematical machinery available, you can see how the beginnings of a metric function for a plan can be built, but a few important details remain. Firstly, while the statistical approaches can make for good estimates, the Ocient System must be able to transform from the domain of SQL types into numbers for each supported SQL type. This is sometimes straightforward in cases like integral and floating point types, but becomes arbitrary and less obvious with things like variable length strings and arrays. Secondly, and more importantly, Ocient must also be able to calculate the metric on *sequences* of operators, each of which can be considered as a separate transformation of input to output. Put another way, if given a sequence of plan operators where each operator is successively operating on rows `T -> P0 -> P1 -> P2 ...`, then the raw column cardinality estimates of the columns in `T` might be of limited use in calculating a metric on `P2` because `P0` and `P1` can drastically alter the statistics of the original table.

In order to account for this, the optimizer must have mathematical models of each operator that can be applied to *input statistics* to produce *output statistics*. Then, successive application of operators can be used to build up plan metrics comprised of per-operator metrics. Clearly, successive approximation incurs increasing error. But an interesting property of using a metric in this manner is that the exact error is not important. Instead, all that is necessary is that the accumulated errors in any estimation must not invalidate the relative comparison between two plans.

The topic of plan optimization is large and complicated, and the Ocient optimizer is a key and integral component of its approach. It incorporates not only detailed implementations but also an integrated view of the distributed nature of the query execution against NVMe drives. Each iterative version of the optimizer also includes an ever-increasing set of optimizations, giving it a sophisticated tool chest of transforms to apply to plans as well.

# Exabyte Scalability Design

How the Ocient System scales to exabyte-class data sets using its distributed compute-adjacent storage architecture, parity, and high-throughput design.

## Cluster of Clusters

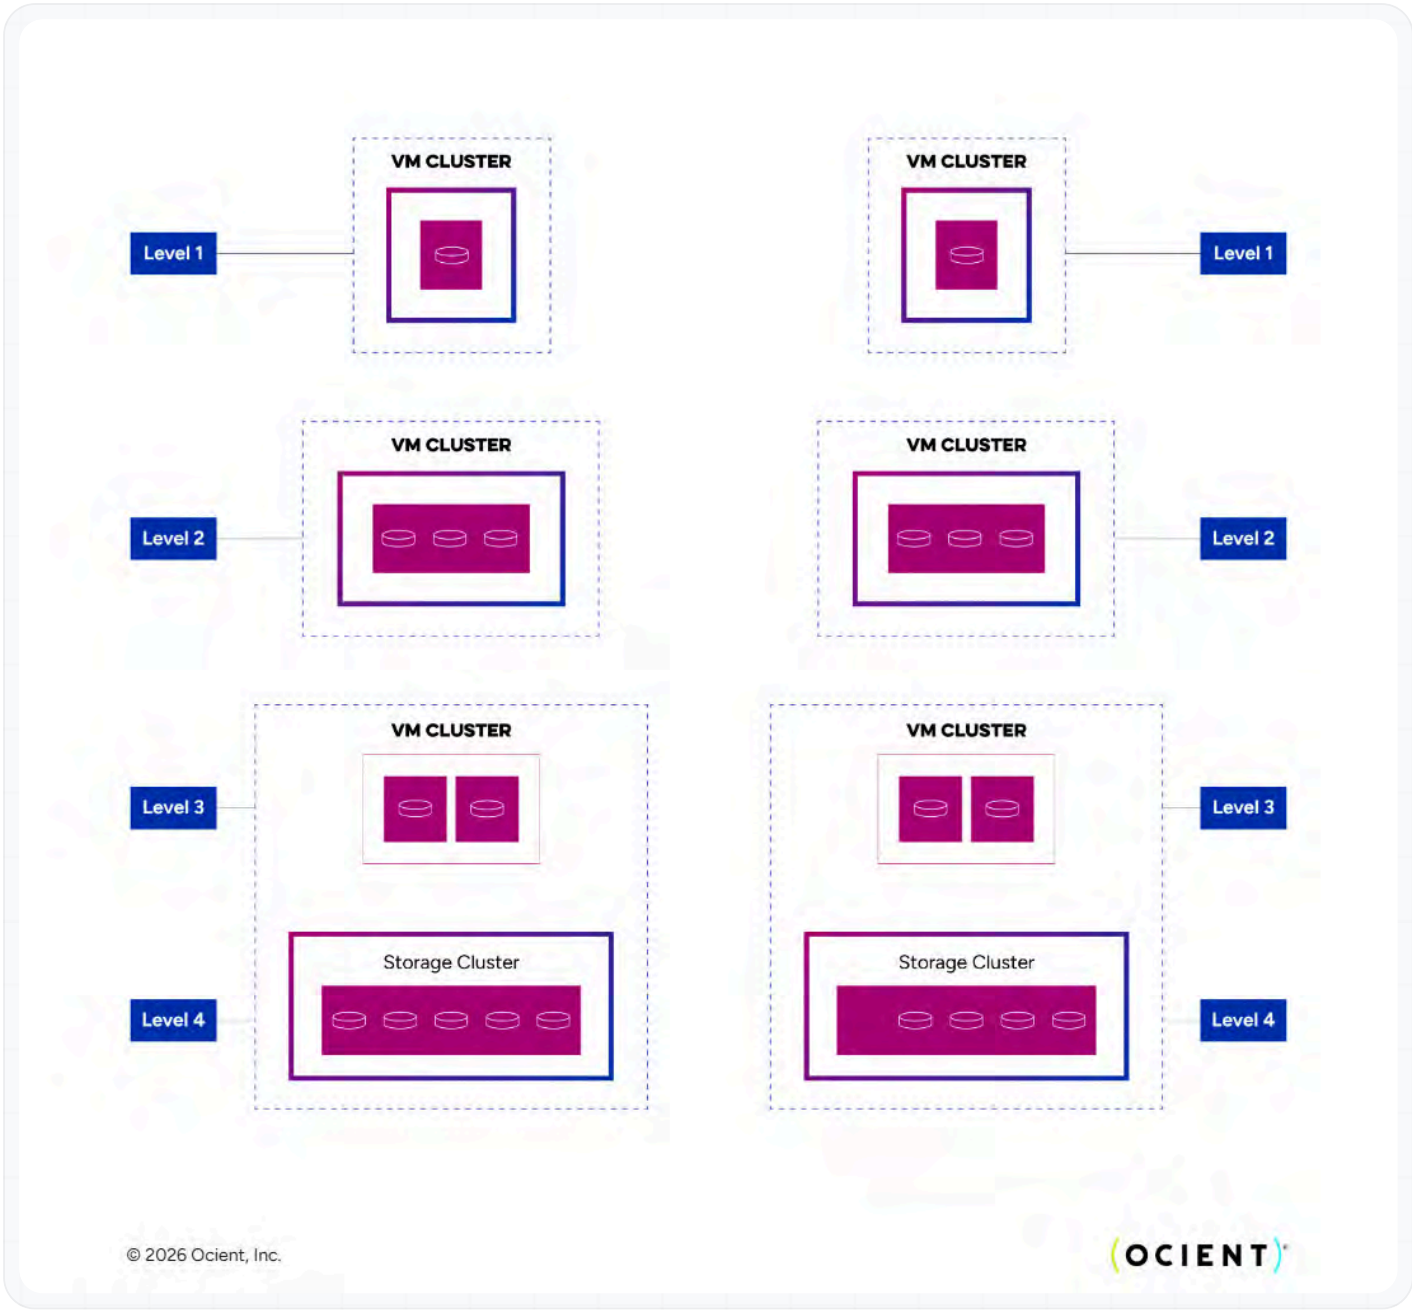
Various system components in Ocient® have each been designed to scale not only with hardware capabilities as technology progresses, but also in number of nodes storing and processing data. Like any distributed system, issues of fault tolerance, availability, and communication all become increasingly challenging as the number of units increases.

The Ocient scalability approach can be broadly described as deriving from ***clusters of clusters***: smaller, locally connected clusters that manage their own availability and local state independently and without consideration to any other clusters in the system. The design goal of this is to minimize global state and global synchronization in any aspect of query processing, fault management, data loading, or data ownership.

There are different kinds of clusters: **metadata** clusters, **storage** clusters, **VM** clusters, and **loading** clusters. An Ocient deployment can contain zero of more of each. With respect to scalability, each cluster runs its own Raft-based consensus protocol and maintains its own local shared state with it. Individual nodes can belong to multiple clusters and participate in multiple disjoint consensus protocols at the same time, but system scalability derives from the fact that no node has any global view of system state, and indeed, no such global state exists.

This allows Ocient to quantify the upper bound on the `N` parameter described in the erasure coding section. Recall that `N` is the number of segments in a segment group. In a **storage cluster**, segment ownership and availability is confined to and maintained in the cluster-local consensus protocol. A necessary implication of data management rules for atomic (but still local) state changes is that *a particular segment group must be stored entirely within one storage cluster.* And because the Ocient System cannot place two segments from the same group onto the same node, the value `N` cannot exceed the number of nodes in a target storage cluster. This finally means that the upper bound on `N` is the practical limit on the consensus protocol

© 2026 Ocient, Inc
Ocient Proprietary and Confidential



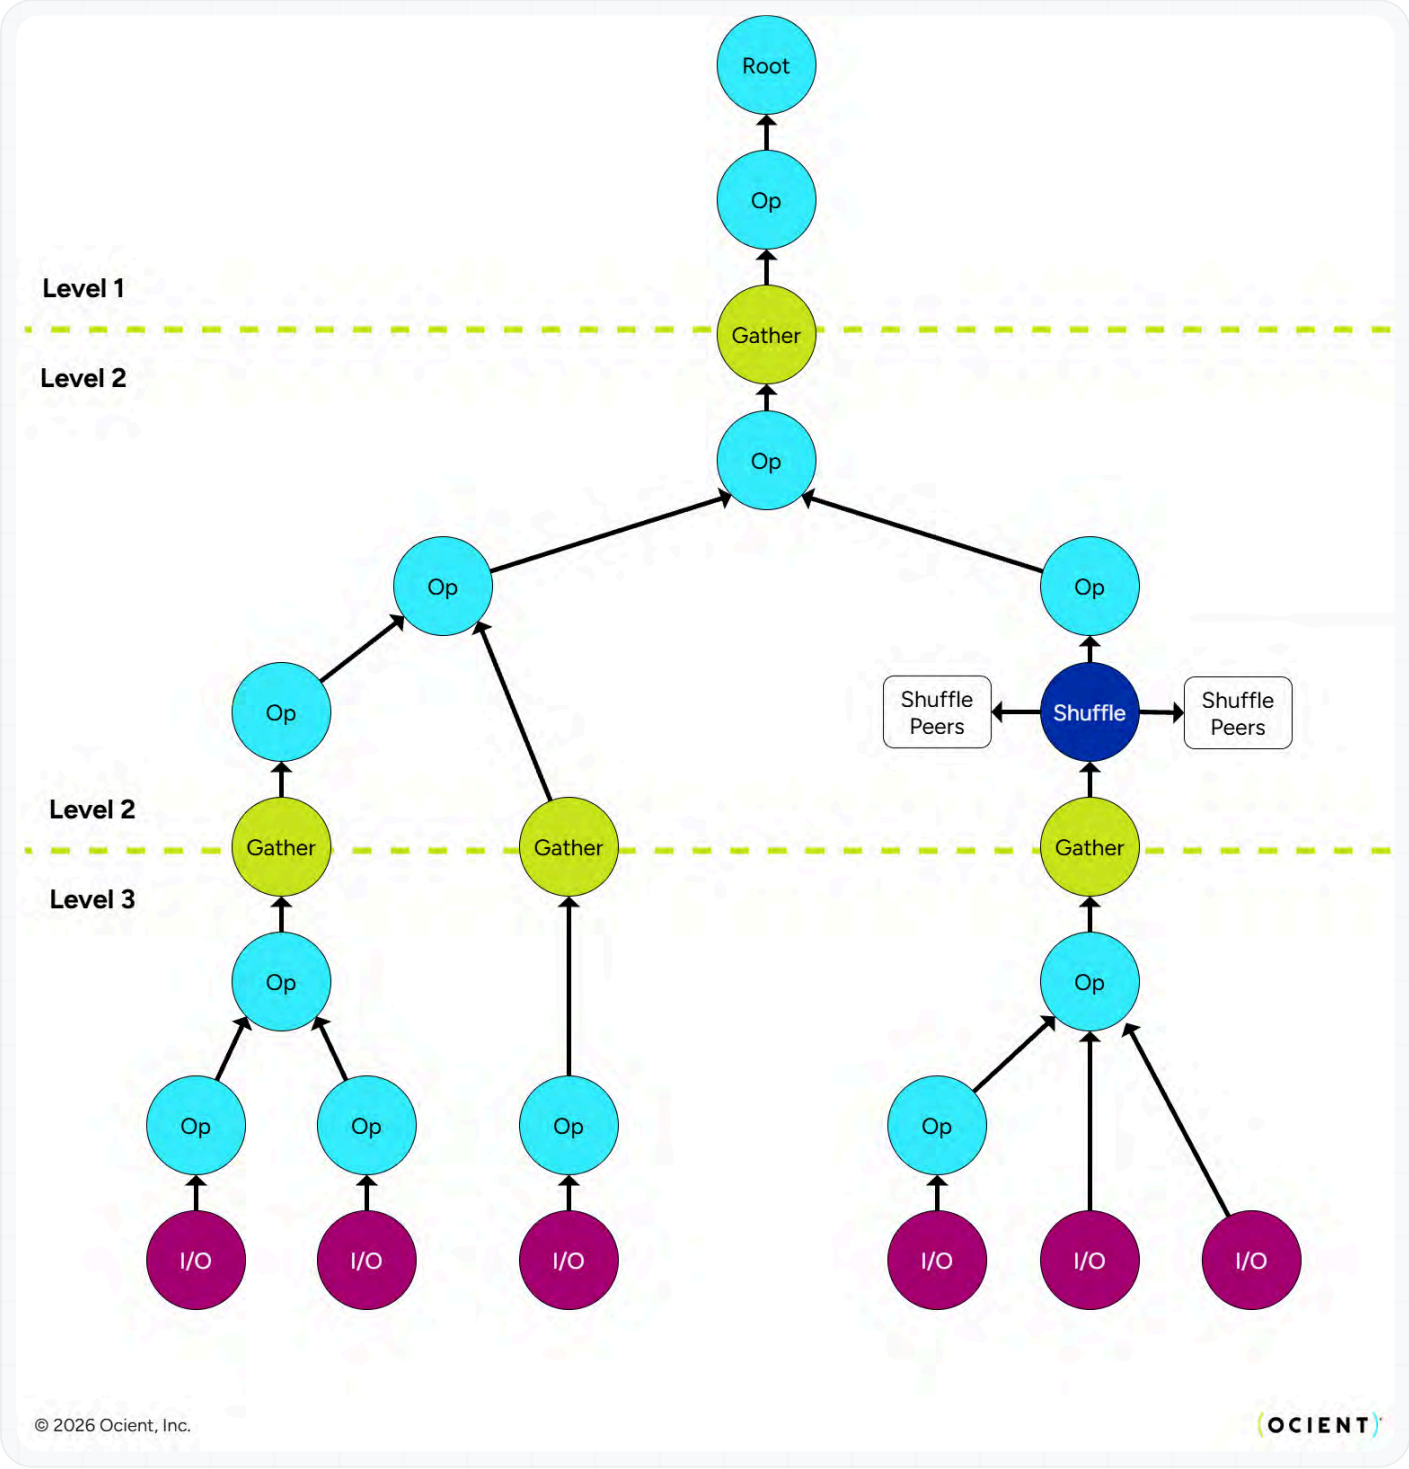
implementation, coupled with the design goal of not allowing clusters to be “too big”: somewhere in the range of 20 - 40, depending on deployment and schema details.

## Query Trees (and Plan Trees)

Query execution necessarily spans multiple VM and storage clusters. A key phase of query processing, prior to any actual computation is the ***query probe***, which establishes the ***query tree*** to be used for that particular query. This tree fixes, for the particular execution with which it is associated, the set of nodes that provide which segments across *all* storage clusters, as well as the set of nodes that co-participate in the distributed execution of the query. The former is important because, as nodes and drives come and go, and as new data is loaded and old data is removed, it is imperative that all segments that should be included in a query are actually included exactly one time. The latter is important because each node might need to know exactly which subset of peers in the network are performing which aspects of query execution. In both cases, the probe phase enables query execution to proceed without any global coordination or synchronization.

This graphic shows a query execution tree, which can scale up by increasing the number of clusters (represented horizontally in the graphic).

© 2026 Ocient, Inc
Ocient Proprietary and Confidential



At the top level of the query execution tree is the root operator, which has zero or more additional plan levels below it, depending on the complexity of the query. Each circle represents individual nodes, which provide segments across the storage clusters or specific tasks for the execution of the query.

Vertically, the graphic shows different plan levels that fan out among the nodes for the stages of the query plan, actions such as transformations, sorting, grouping or other operations. The leaf level at the bottom of the graphic represents the I/O operation that reads the queried data from storage.

When the system initiates query execution, each cluster executes its operations in parallel. For the most part, clusters operate in isolation unless they need to communicate for operations such as a join or shuffle.

When referring to the query plan, each level is delineated by the presence of a special ***gather operator*** that represents the network boundary between levels. All the plan operators between root and the first gather operator are said to *execute at level 1.* Any plan operators that exist between the first gather operator and the second gather operator execute at level 2, and so on, until the final gather operator and the set of operators below it until the leaf I/O operators that represent the leaf level.

When referring to the query tree, each gather operator represents a fan-out from one level N gather operator to some fixed number of N+1 nodes. During execution, a specific level N node is responsible for coordinating and amalgamating partial query

results from the level N+1 nodes below it. By definition, there is exactly one level 1 node in a query, fanning out to some number of level 2 nodes, each of which itself fans out to some number of level 3 nodes, and so on. The fan-out factor is closely aligned with the cluster sizes in use.

In both cases, the tree structure promotes scalable query execution in a fault-tolerant way.

**At the Whiteboard with Ocient: Scale**

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# Loading Characteristics and Concepts

Core concepts behind data loading in Ocient, including parallelism, batching, deduplication, time-key partitioning, and end-to-end throughput considerations.

When considering trillions or quadrillions of distinct records being stored and accessed as part of an ever-growing data warehouse, the manner in which data is loaded is important. The loading infrastructure of the data warehouse must not only provide strong correctness and durability guarantees in service of modern data pipelines, but must do so at very high load rates as well. For example, if an individual record averages 1000 bytes in size and the data warehouse must store 100 trillion records, the size of the records to be loaded is 10^14 * 10^3 = 10^17 bytes, or 100 petabytes. Note that this is *pre-compression* because this is the volume of data that will be presented, row by row, to the data warehouse. If this information represents one year's worth of records, the loading system must be prepared to handle a steady-state average of ~25 Gbps. When the data rate is not completely uniform in time (perhaps displaying cyclic behavior associated with the day/night cycle) it is easy to imagine the required load rate can measure in the 100's, or even 1000's of Gbps.

Obviously, the sizes and rates are arbitrary, but they are not unrealistic. Consequently, a high-throughput, scalable, and robust loading infrastructure is a first-class citizen in an on-par complexity-wise with the execution engine itself.

## Record-Level Resolution

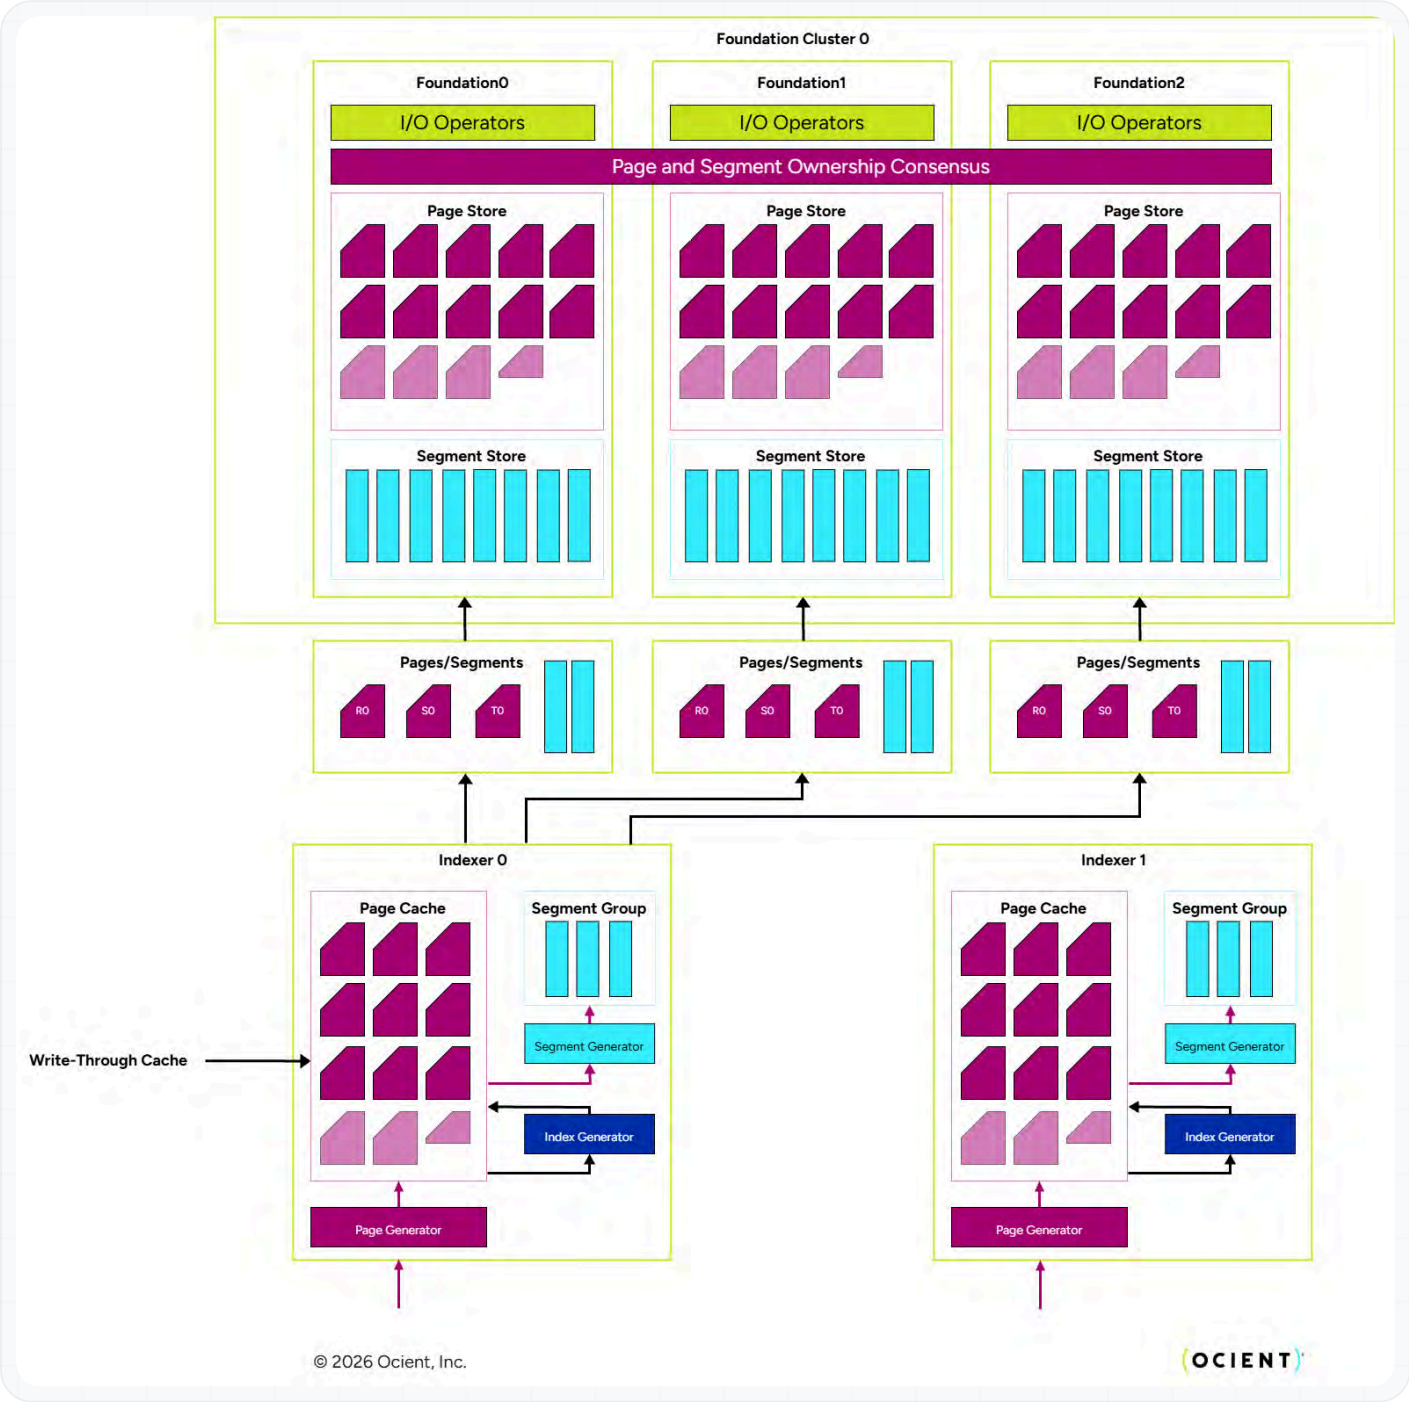
The distinction between "stream" and "batch" is somewhat arbitrary, depending on the system in consideration, but in the Ocient® loading infrastructure the fundamental unit of loading is a single record in a table. Put another way, the various guarantees listed here are made on a record-by-record basis and not on batches of records. Supporting this is the concept of a ***record stream*** of which the loading infrastructure can manage an unbounded number. A record stream is an ordered sequence of records, and loading considers each record in a stream independently of each other.

© 2026 Ocient, Inc

## Low Latency Querying

A key design goal of the loading system was a low ***time to query-ability*** or ***TTQ***. Strict guarantees are not made but this usually means that any record presented to the loading system is available to be queried on the order of seconds. An interesting property of the implementation is that the variance on TTQ *decreases* as the aggregate record rate *increases.* This is because the loading system maintains internal structures named ***pages*** that accumulate records, and the faster they fill the more quickly they are made available for querying.

## Low Latency Durability



A necessary requirement of low-latency querying is the ability to ensure that any particular record is stored in a fault-tolerant manner. To guarantee correctness of query results it must be the case that when a record is considered during query execution (either included or filtered out) it must be considered for *all* subsequent queries until it is deleted by the user. The ***durability*** guarantee made by the loading system must come before query-ability (and therefore is measured in seconds on a record-by-record basis) and matches the system's configured fault tolerance. For example, if the erasure coding scheme in use has a `K` value of 2, then the loading system must store all records in a manner that allows for at least 2 losses before they can be made queryable.

The unit of durability in the loading system is named a ***page*** and within the loading and storage system, a page shares many characteristics with the segments: each page is a self-contained set of records and their own local metadata and statistics, and the consensus-based ownership scheme mediated by the storage clusters is the same for both. However, there are some key distinctions:

1. **Typical Size** — A page is usually substantially smaller than a segment. While segments can be multiple gigabytes in size, pages are more commonly around 100 megabytes.
2. **Replication** — Segments are grouped together into segment groups and mutually erasure coded for fault tolerance. Pages, however, are *replicated* within the storage layer. This is less space efficient for the same fault tolerance, but pages are short-lived: they exist only long enough to be converted into segments, which are denser and richer in metadata. Because they do not exist for very long, the extra storage

© 2026 Ocient, Inc

overhead of the replication scheme is inconsequential, and the loading system opts not to waste the computational effort computing the erasure-coded parity data.

## Exactly-Once Guarantee

When the record stream sources can support it, the Ocient loading infrastructure is capable of providing exactly-once semantics for every record loaded. This means that the record source and the query layer can be guaranteed that every record presented for load is not only not lost (no “gaps” exist) but also not duplicated. On the surface, this seems like an obvious and simple requirement, but at millions of records per

second in a fault-tolerant distributed system, it is extremely non-trivial to provide this guarantee.

The loading systems of other database engines can also provide this guarantee, but often with caveats that might not be acceptable. For example, executing a sequence of `INSERT INTO` statements within the context of a transaction is a possible approach, but distributed transaction processing does not easily scale to millions of records per second. Beyond that, there is the issue of how to manage inter-transaction guarantees that place additional requirements on the data sources.

If transactions are not in use, it is generally not possible to provide exactly-once guarantees without a bi-directional contract executed by the record source and the loading system. In a very common form of this contract, the loading system provides the exactly-once guarantee by guaranteeing it will de-duplicate any records presented more than once (i.e., the loading system is *idempotent* with respect to record insertions). Then, the source can safely re-send any records the loading system does not indicate it has received. So long as the source resends anything it has not been explicitly told was received (and made durable) the two endpoints can together guarantee every record will be present exactly one time.

When this approach is taken, the loading system's job becomes simple deduplication. On some systems, this is achieved using unique record identifiers. First, the source must be able to indicate a column or set of columns whose values taken together for any particular record uniquely identify it. Then, for each record inserted, a hash set or other structure is consulted. If the unique identifier is not present, it is inserted, if it is, the record is silently dropped. While technically cheap to implement, this scheme suffers because the set structure cannot be allowed to grow indefinitely, and therefore some time or size based bound is placed on the exactly-once guarantee. An additional significant issue is that it is challenging and expensive to ensure the set structure is replicated or distributed amongst all nodes participating in the loading system. This presents correctness and scalability challenges to the exactly-once guarantee.

The Ocient loading system takes the idempotent deduplication approach, but performs its deduplication checks in a different manner. The crux of the scheme is that most systems that aim for exactly-once guarantees are also able to replay their record streams *in the same order*. This is true for queuing systems such as Apache® Kafka® as well as file sources such as Apache® Parquet™ files stored in Amazon® Web Services℠ (AWS℠) S3. Due to this property, the Ocient deduplication scheme tracks a

***durability horizon*** for each distinct record stream. Recall that a record stream is an *ordered* sequence of records. The durability horizon is an ever-advancing offset into a stream that indicates the record at which the data warehouse guarantees all previous records up to and including that record, for that stream, are guaranteed durable. Using this scheme, the source can easily identify the set of records it should send or re-send. In the loading system, deduplication becomes cheap in both time and space: the system need only store the durability horizon per stream (instead of an unbounded set), and deduplication checks are as simple as a basic interval check comparing whether or not sequences of records stored in pages overlap.

## Linear Scalability at High Rates

In order to enable the extremely high record and bit rates associated with hyperscale data pipelines, it is important that the loading system be capable of scaling linearly to address arbitrary loading complexity. The Ocient loading layer achieves true linear scalability due to a shared-nothing approach between nodes executing loading operations. Being linearly scalable, it is relatively straightforward to design a fault-tolerant deployment that can handle any arbitrary rate by simply multiplying by the capabilities of a single node for a specified schema.

With that said, it is almost impossible to specify an exact achievable load rate on a per-node basis in advance. This is because the process is bound by the computational complexity of calculating indexes and metadata (which are schema-specified), the width of the erasure coding scheme (which are user-specified), and the bit rate being handled (which is both schema *and* data-dependent). With that said, each Loader Node is usually bounded by memory bandwidth, and it is not uncommon to be capable of steady-state load rates per node measuring in dozens of gigabits per second or millions of records per second. Usually, nodes are also capable of bursting to higher rates: 10’s of millions of records per second and approaching 100 Gbps.

## Conclusion

The architecture is designed to maximize performance on the world’s largest data sets. The massively parallel Compute Adjacent Storage Architecture® features storage and query processing optimizations to achieve scalable performance on commodity hardware with NVMe SSD storage. The custom-built, fully-integrated SQL execution engine and optimizer deeply integrate with the storage and the input and output layer.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

The result is a state-of-the-art data warehouse that can deliver outstanding performance loading and querying record sets numbering in the trillions, quadrillions, and beyond.

# Alphabetical SQL Functions List

Alphabetical reference of all SQL functions in Ocient, including math, string, date, conversion, geospatial, machine learning, and aggregates.

| Function Name | Category Name | Function Description |
|---|---|---|
| **ABS** | Math Functions | Returns the absolute value of a spec |
| **ABS** | Matrix Functions | Returns the magnitude of one-dimer |
| **ACOS** | Math Functions | Returns the inverse cosine of a spec |
| **ACOSH** | Math Functions | Returns the hyperbolic arc-cosine of |
| **ACCURACY_SCORE** | Aggregate Functions | Returns the fraction of predictions th |
| **ADD_MONTHS** | Date and Time Functions | Adds the specified number of month |
| **ANY_VALUE** | Aggregate Functions | Returns an arbitrary, non-NULL valu |
| **APPROX_COUNT_DISTINCT** | Aggregate Functions | Approximate distinct count by using |
| **APPROX_SUM** | Aggregate Functions | Allows the aggregation engine to us |
| **ARRAY[]** | Array Functions | PostgreSQL®-compliant constructor |
| **ARRAY_AGG** | Aggregate Functions | Returns an array containing every ro |
| **ARRAY_APPEND** | Array Functions | Add value to the back of an array. |
| **ARRAY_ARGMAX** | Array Functions | Returns the corresponding argmax c |
| **ARRAY_ARGMIN** | Array Functions | Returns the corresponding argmin o |
| **ARRAY_CAT** | Array Functions | Concatenate 2 arrays into a new one |
| **ARRAY_CAT_DISTINCT** | Array Functions | Concatenates two or more arrays in |
| **ARRAY_CAP** | Special Data Pipeline Transformation Functions | Restrict the length of an array to a r |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **ARRAY_COMPACT** | Special Data Pipeline Transformation Functions | Removes NULL values from the arra |
| **ARRAY_CONCAT_AGG** | Aggregate Functions | Returns an array that concatenates |
| **ARRAY_CONTAINS** | Special Data Pipeline Transformation Functions | Returns `true` if the array contains |
| **ARRAY_DISTINCT** | Array Functions | Removes duplicates from an array w |
| **ARRAY_INTERSECT_DISTINCT_COUNT** | Array Functions | Returns the count of distinct elemer |
| **ARRAY_LENGTH** | Array Functions | Return the number of elements of a |
| **ARRAY_MAX** | Array Functions | Returns the corresponding maximur |
| **ARRAY_MIN** | Array Functions | Returns the corresponding minimum |
| **ARRAY_POSITION** | Array Functions | Returns the position of the first mat |
| **ARRAY_POSITIONS** | Array Functions | Returns all elements stored in the ri |
| **ARRAY_PREPEND** | Array Functions | Add value to the front of an array. |
| **ARRAY_REMOVE** | Array Functions | Remove value from the array. |
| **ARRAY_REPLACE** | Array Functions | Replace value by another in an arra |
| **ARRAY_SORT** | Special Data Pipeline Transformation Functions | Sort and return the input array base |
| **ARRAY_SUM** | Array Functions | Returns the sum of the array. The ar contribute to the sum. |
| **ARRAY_TO_STRING** | Array Functions | Converts array to a list of elements |
| **ARRAY_TRANSFORM** | Array Functions | Transforms one or more arrays using element-wise. |
| **ARRAY_TRANSFORM_WITH_ORD** | Array Functions | Transforms an array using a lambda |
| **ASCII** | Character and Binary Functions | Returns the ASCII code value of the |
| **ASIN** | Math Functions | Returns the inverse sine of a specifi |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ASINH** | Math Functions | Returns the hyperbolic arc-sine of a |
| **ATAN** | Math Functions | Returns the inverse tangent of a spe |
| **ATAN2** | Math Functions | Returns the inverse tangent of two r |
| **ATANH** | Math Functions | Returns the hyperbolic arc-tangent c |
| **AVG** | Aggregate Functions | Average, or arithmetic mean, over t |
| **BICDF** | Math Functions | The cumulative distribution function |
| **BIGINT** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **BINARY** | Scalar Data Conversion Functions | Parses a hexadecimal string (such a |
| **BIPDF** | Math Functions | The probability density function of tl |
| **BIT_LENGTH** | Character and Binary Functions | Returns the length of the character |
| **BITAND** | Math Functions | Alias for the BITFUNC syntax `BITFUI` |
| **BITFUNC** | Math Functions | Performs a variety of bit operations. |
| **BITNOT** | Math Functions | Returns the bitwise negation of inte |
| **BITOR** | Math Functions | Alias for the BITFUNC syntax BITFUN |
| **BITXOR** | Math Functions | Alias for the BITFUNC syntax BITFUN |
| **BOOLAND** | Math Functions | Alias for the BOOLFUNC syntax BOO |
| **BOOLEAN** | Scalar Data Conversion Functions | Parses a string to create a Boolean v |
| **BOOLFUNC** | Math Functions | Performs a Boolean logical evaluatic `'XOR'`. |
| **BOOLNOT** | Math Functions | Returns the logical negation of the E |
| **BOOLOR** | Math Functions | Alias for the BOOLFUNC syntax BOO |
| **BOOLXOR** | Math Functions | Alias for the BOOLFUNC syntax BOO |
| **BTRIM** | Character and Binary Functions | Alias for TRIM. |

| Function Name | Category Name | Function Description |
|---|---|---|
| **BYTE** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **CANCEL** | Query Management | Cancels a running query based on it |
| **CASE** | Conditional Functions | CASE operates similarly to condition then / else statement or as a switch |
| **CASE WHEN** | Special Data Pipeline Transformation Functions | Returns the `result` value based or |
| **CAST_TO_ARRAY** | Array Functions | Casts the elements of the array to a |
| **CAST_TO_TUPLE** | Tuple Functions | Converts a tuple into another tuple |
| **CBRT** | Math Functions | Returns the cube root of the numeri |
| **CDF** | Math Functions | The cumulative distribution function sample is less than or equal to the s |
| **CEIL** | Math Functions | Returns the nearest integer greater |
| **CEILING** | Math Functions | Alias for CEIL. |
| **CENTURY** | Date and Time Functions | Returns the number of centuries. |
| **CHAR** | Array Functions | Converts array to its string represen |
| **CHAR** | Scalar Data Conversion Functions | Creates a string version of the nume |
| **CHAR** | Tuple Functions | Converts a tuple to its string represe |
| **CHAR_LENGTH** | Character and Binary Functions | Alias for LENGTH. |
| **CHARACTER_LENGTH** | Character and Binary Functions | Alias for LENGTH. |
| **CHR** | Character and Binary Functions | Converts an integer value to a string |
| **COALESCE** | Conditional Functions | Evaluates to the first argument that |
| **COEFFICIENT_OF_DETERMINATION** | Aggregate Functions | Computes the coefficient of determi |

| Function Name | Category Name | Function Description |
|---|---|---|
| **COMMIT** | Other Functions and Expressions | Returns the most recent commit has |
| **CONCAT** | Character and Binary Functions | Concatenates two values, which mu the \|\| operator. |
| **CONFUSION_MATRIX** | Aggregate Functions | Returns a structured representation to a specified positive class. |
| **CONVERT_LOCAL_TIMESTAMP_TO_UTC** | Time Zone Functions | The function converts a timestamp i |
| **CONVERT_UTC_TIMESTAMP_TO_LOCAL** | Time Zone Functions | The function converts a timestamp f |
| **CORR** | Aggregate Functions | Alias for CORRELATION. |
| **CORRELATION** | Aggregate Functions | Sample correlation. |
| **CORRELATIONP** | Aggregate Functions | Population correlation. |
| **COS** | Math Functions | Returns the cosine of x. |
| **COSH** | Math Functions | Returns the hyperbolic cosine of x. |
| **COT** | Math Functions | Returns the cotangent of x. |
| **COUNT** | Aggregate Functions | Number of rows in the set. |
| **COVAR_POP** | Aggregate Functions | Alias for COVARIANCEP. |
| **COVAR_SAMP** | Aggregate Functions | Alias for COVARIANCE. |
| **COVARIANCE** | Aggregate Functions | Sample covariance. |
| **COVARIANCEP** | Aggregate Functions | Population covariance. |
| **CROSS_ENTROPY_LOSS** | Array Functions | Returns the cross entropy loss of tw |
| **CROSS_ENTROPY_LOSS** | Matrix Functions | Returns the cross entropy loss of tw |
| **CUME_DIST** | Window Aggregate Functions | Returns a number 0 < n 1 and can b value in the group. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **CURDATE** | Date and Time Functions | Alias for CURRENT_DATE. |
| **CURRENT_DATABASE** | System Functions | Alias for DATABASE. |
| **CURRENT_DATE** | Date and Time Functions | Returns the current date in the form |
| **CURRENT_GROUPS** | System Functions | Returns the fully-qualified names of |
| **CURRENT_NODE** | System Functions | Returns the name of the SQL Node v column in the `sys.nodes` system ca |
| **CURRENT_NODE_ID** | System Functions | Returns the identifier of the SQL Noc |
| **CURRENT_SCHEMA** | System Functions | Returns the name of the current sch |
| **CURRENT_SESSION_ID** | System Functions | Returns the Universally Unique IDen |
| **CURRENT_SYSTEM** | System Functions | Returns the name of the system. |
| **CURRENT_TIME** | Date and Time Functions | Returns the current time as a TIME v |
| **CURRENT_TIMESTAMP** | Date and Time Functions | Returns the current date and time a |
| **CURRENT_USER** | System Functions | Returns the user for the current con |
| **DATABASE** | System Functions | Returns the name of the database t |
| **DATE** | Scalar Data Conversion Functions | Parses a string in the form 'YYYY-MM |
| **DATE_PART** | Date and Time Functions | Alias for EXTRACT. |
| **DATE_TRUNC** | Date and Time Functions | Returns the date or timestamp ente |
| **DATEADD** | Date and Time Functions | Adds a specified number value (as a that modified value. |
| **DATEDIFF** | Date and Time Functions | This function returns an INT represe unit. |
| **DAY** | Date and Time Functions | Alias for DAY_OF_MONTH. |
| **DAY_OF_MONTH** | Date and Time Functions | Extracts the day-of-month portion of |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **DAY_OF_WEEK** | Date and Time Functions | Returns an integer, in the range of 1 |
| **DAY_OF_YEAR** | Date and Time Functions | Returns an integer in the range 1 to |
| **DAYS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **DECADE** | Date and Time Functions | The decade is the year divided by 1( |
| **DECIMAL** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **DEGREES** | Math Functions | Returns the corresponding angle in ( |
| **DELTA** | Window Aggregate Functions | Computes the finite difference betw backwards difference, which means of expression for that row and the p |
| **DENSE_RANK** | Window Aggregate Functions | Assigns a number to each row in the between ranks. |
| **DERIVATIVE** | Window Aggregate Functions | Computes the difference quotient be |
| **DET** | Matrix Functions | Returns the determinant of the matr |
| **DIV** | Math Functions | Returns the result of x divided by y. |
| **DOT** | Matrix Functions | Returns dot product of two one-dime |
| **DOUBLE** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **DOW** | Date and Time Functions | Alias for DAY_OF_WEEK. |
| **DOY** | Date and Time Functions | Alias for DAY_OF_YEAR. |
| **EIGEN** | Matrix Functions | Returns eigenvalues and eigenvalue |
| **ELEMENT_AT** | Special Data Pipeline Transformation Functions | Returns the element value of the arr |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **ENDSWITH** | Character and Binary Functions | Returns true if x ends with y and fal |
| **EOMONTH** | Date and Time Functions | Returns the last day of the timestam |
| **EPOCH** | Date and Time Functions | The number of seconds after 1970-( |
| **ERF** | Math Functions | The error function is used for measu |
| **ERFC** | Math Functions | The complement of the error functic |
| **EXP** | Math Functions | Returns the exponential of x (e raise |
| **EXPLODE_OUTER** | Special Data Pipeline Transformation Functions | Expands a one-dimensional or multi system. |
| **EXTRACT** | Date and Time Functions | Extract a component from a timesta |
| **F1_SCORE** | Aggregate Functions | Returns the harmonic mean of preci |
| **FILTER** | Special Data Pipeline Transformation Functions | Filters elements in an array based o |
| **FIRST_VALUE** | Window Aggregate Functions | Returns the first value in the ordere |
| **FLATTEN** | Special Data Pipeline Transformation Functions | Transforms an `N`-dimensional array |
| **FLOAT** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **FLOOR** | Math Functions | Returns the nearest integer less tha |
| **FROBENIUS** | Matrix Functions | Returns the Frobenius norm of a ma |
| **GAMMA** | Math Functions | **Gamma function.** |
| **GREATEST** | Conditional Functions | Returns the largest non-NULL value |

| Function Name | Category Name | Function Description |
|---|---|---|
| **HASH** | Scalar Data Conversion Functions | Creates a fixed length binary value, string does not have enough bytes, |
| **HEXBINX** | Math Functions | Returns the x-coordinate of the cent |
| **HEXBINY** | Math Functions | Returns the y-coordinate of the cent |
| **HINGE_LOSS** | Array Functions | Returns the hinge loss of two arrays |
| **HINGE_LOSS** | Matrix Functions | Returns the hinge loss of two one-di |
| **HLL_SKETCH_CREATE** | HyperLogLog Functions | Creates an HLL sketch from the data representation of the sketch that yo |
| **HLL_SKETCH_GET_ESTIMATE** | HyperLogLog Functions | The scalar function converts a sketc estimate as a BIGINT. |
| **HLL_SKETCH_GET_ESTIMATE_BOUND** | HyperLogLog Functions | Takes a HLL_SKETCH column or an ir confidence interval error proportion |
| **HLL_SKETCH_TO_STRING** | HyperLogLog Functions | The HLL_SKETCH_TO_STRING scalar the sketch. |
| **HLL_SKETCH_UNION (aggregate function)** | HyperLogLog Functions | Merges multiple sketches in a single function is an aggregate function an |
| **HLL_SKETCH_UNION (scalar function)** | HyperLogLog Functions | Merges two sketches into a new con function merges two sketch columns |
| **HOUR** | Date and Time Functions | Extracts the hour portion of a timest |
| **HOURS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **IDENTITY_MATRIX** | Matrix Functions | Returns an identity matrix of the spe |
| **IERF** | Math Functions | The inverse of the ERF error functior |
| **IERFC** | Math Functions | The inverse of the complement of th |
| **IF** | Special Data Pipeline Transformation Functions | Returns `T` if the expression `X` ev |
| **IF_NULL** | Conditional Functions | Alias for COALESCE. |
| **INITCAP** | Character and Binary Functions | For each word in the provided string |

| Function Name | Category Name | Function Description |
|---|---|---|
| **INSTR** | Character and Binary Functions | Returns the index position of the firs value char by ignoring case. |
| **INTEGER** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **INVERSE** | Matrix Functions | Returns inverse of a square, invertib |
| **IP** | Network Type Functions | Casts an IP data type from an IPV4 c |
| **IPV4** | Network Type Functions | Casts an IPV4 address from an IPV6 |
| **ISDATE** | Date and Time Functions | Returns TRUE if the input argument |
| **IS_IPV4** | Network Type Functions | Tests whether the database can con |
| **ISODOW** | Date and Time Functions | Extracts the day of the week based |
| **JACCARD_SIMILARITY** | Array Functions | Returns the Jaccard similarity coeffic |
| **JSON_EXTRACT_PATH_TEXT** | Character and Binary Functions | Returns the value for the key-value |
| **KILL** | Query Management | Kills a running query identified by its |
| **KURTOSIS** | Aggregate Functions | The sample over the set. |
| **KURTOSISP** | Aggregate Functions | The population over the set. |
| **LAG** | Window Aggregate Functions | Returns the row, which is the specifi |
| **LAG_VECTORS** | Data Preparation | Groups lagged columns generated b |
| **LAGS** | Data Preparation | Generates a series of lagged columr |
| **LAGS_ZEROFILL** | Data Preparation | Generates lagged columns for a sing |
| **LAST_VALUE** | Window Aggregate Functions | Returns the last value in the orderec |
| **LCASE** | Character and Binary Functions | Alias for LOWER. |

| Function Name | Category Name | Function Description |
|---|---|---|
| **LEAD** | Window Aggregate Functions | Returns the row, which is the specifi |
| **LEAKYRELU** | Math Functions | Returns the leaky rectified linear uni |
| **LEAST** | Conditional Functions | Returns the smallest non-NULL valu |
| **LEFT** | Character and Binary Functions | Return the number of characters in t returns all but the last integer chara |
| **LEFT_SHIFT** | Math Functions | Returns x shifted to the left by y bits |
| **LENGTH** | Character and Binary Functions | For character data types, this value |
| **LN** | Math Functions | Returns the natural logarithm of x. |
| **LOCATE** | Character and Binary Functions | Alias for POSITION. Returns the inde value string. |
| **LOG** | Math Functions | Returns the base 10 logarithm of x. the function defaults to base 10. |
| **LOG_GAMMA** | Math Functions | The natural logarithm of the absolut |
| **LOG_LOSS** | Array Functions | Returns the log loss of two arrays. |
| **LOG_LOSS** | Matrix Functions | Returns the log loss of two one-dime |
| **LOG2** | Math Functions | Returns the base 2 logarithm of x. |
| **LOGITS_LOSS** | Array Functions | Returns the logits loss of two arrays |
| **LOGITS_LOSS** | Matrix Functions | Returns the logits loss of two one-di |
| **LOOKUP** | Special Data Pipeline Transformation Functions | Look up and load data in an externa |
| **LOWER** | Character and Binary Functions | Alias for LCASE. Convert string to lo |
| **LPAD** | Character and Binary Functions | Pad the input text to the specified le |
| **LTRIM** | Character and Binary Functions | Removes leading blanks from the st |
| **LUPQ_DECOMP** | Matrix Functions | Returns LUPQ decomposition of a sq |
| **MAP_DELETE** | Scalar Data Conversion | Removes the entry for the specified |

| Function Name | Category Name | Function Description |
| --- | --- | --- |
| | Functions | |
| **MAP_GET** | Scalar Data Conversion Functions | Returns the value for the specified k |
| **MAP_KEYS** | Special Data Pipeline Transformation Functions | Returns the keys in the specified JSC |
| **MAP_PUT** | Scalar Data Conversion Functions | Inserts a key-value pair into a map c |
| **MAP_VALUES** | Special Data Pipeline Transformation Functions | Returns the values in the specified J |
| **MATRIX_DIM** | Matrix Functions | Returns the dimensions of the speci |
| **MAKE_MATRIX_IXJ** | Matrix Functions | Creates an `ixj` matrix with elemer |
| **MAKEDATETIME** | Date and Time Functions | Returns a timestamp consisting of th |
| **MATRIX_FROM_TEXT** | Matrix Functions | Creates a matrix from the specified |
| **MATRIX_TRACE** | Matrix Functions | Returns trace of a square matrix as |
| **MAX** | Aggregate Functions | Maximum value in the specified colu |
| **MD5** | Character and Binary Functions | Returns the hexadecimal string (all l |
| **MEAN_ABSOLUTE_ERROR** | Aggregate Functions | Returns the mean absolute error (MA |
| **MEAN_ABSOLUTE_PERCENTAGE_ERROR** | Aggregate Functions | Returns the mean absolute percenta |
| **METADATA** | Special Data Pipeline Transformation Functions | Extracts the metadata value for the |
| **MICROSECONDS** | Scalar Data Conversion Functions | Converts an integral value to an inte |

| Function Name | Category Name | Function Description |
|---|---|---|
| **MID** | Character and Binary Functions | Alias for SUBSTRING. |
| **MILLISECOND** | Date and Time Functions | Extracts the millisecond portion of a |
| **MILLISECONDS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **MIN** | Aggregate Functions | Minimum value in the specified colu |
| **MINUTE** | Date and Time Functions | Extracts the minute portion of a tim |
| **MINUTES** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **MOD** | Math Functions | Returns the remainder from x divide |
| **MONTH** | Date and Time Functions | Extracts the month portion of a time |
| **MONTH_NAME** | Date and Time Functions | Returns the calendar name in Englis |
| **MONTHS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **MONTHS_BETWEEN** | Date and Time Functions | Returns the difference between the |
| **MSECS** | Date and Time Functions | The seconds field, including fraction |
| **MULTI_LAGS** | Data Preparation | Generates lagged columns for multi |
| **MULTI_LAGS_ZEROFILL** | Data Preparation | Generates lagged columns for multi |
| **MURMUR3** | Conditional Functions | **Returns a 32-bit MurmurHash3 I** |
| **NANOS_TO_TIMESTAMP** | Date and Time Functions | Convert a number of nanoseconds i |
| **NANOSECONDS** | Scalar Data Conversion Functions | Converts an integral value to an inte |

| Function Name | Category Name | Function Description |
|---|---|---|
| **NEXT_DAY** | Date and Time Functions | Returns the closest date after a spe |
| **NOW** | Date and Time Functions | Alias for CURRENT_TIMESTAMP. |
| **NTH_VALUE** | Window Aggregate Functions | Returns the nth value in the orderec |
| **NULL_IF** | Conditional Functions | Returns the NULL value if two argum |
| **NULL_MATRIX** | Matrix Functions | Returns a null matrix of the given (r |
| **OCTET_LENGTH** | Character and Binary Functions | Returns the length in bytes of a cha |
| **PARSE_DELIMITED_ARRAY** | Special Data Pipeline Transformation Functions | Converts a string of text data repres |
| **PERCENT_RANK** | Window Aggregate Functions | The value returned is 0 < n ≤ 1 and excluding the highest value. |
| **PERCENTILE** | Window Aggregate Functions | Returns the value that corresponds |
| **PI** | Math Functions | Returns the constant value of π. |
| **PMOD** | Math Functions | Returns the smallest non-negative e |
| **POSITION** | Character and Binary Functions | Alias for LOCATE. |
| **POWER** | Math Functions | Returns x raised to the power of y. |
| **PRECISION_SCORE** | Aggregate Functions | Returns the precision score for a spe |
| **PROBIT** | Math Functions | The inverse of the cumulative distrib |
| **PRODUCT** | Aggregate Functions | Product over the set. |
| **QR_DECOMP** | Matrix Functions | Returns QR decomposition of a matr |
| **QUARTER** | Date and Time Functions | Returns an integer between 1 and 4 |
| **RADIANS** | Math Functions | Returns the corresponding angle in r |
| **RAND** | Math Functions | Takes no argument and returns a ra |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
| --- | --- | --- |
| **RAND_UUID** | Other Functions and Expressions | Generates a random UUID value (ve |
| **RANK** | Window Aggregate Functions | Assigns a number to each row in the between ranks. |
| **RATIO_TO_REPORT** | Window Aggregate Functions | Computes the ratio of a value to the |
| **RECALL_SCORE** | Aggregate Functions | Returns the recall score for a specifi |
| **ROC_AUC_SCORE** | Aggregate Functions | Returns the area under the receiver |
| **RECORD_UUID** | Other Transformation Functions | Returns string that represents a unic topic. |
| **REDUCE** | Special Data Pipeline Transformation Functions | Applies a merge function to a startir value. Optionally, specify a finish fu |
| **REGEXP_COUNT** | Character and Binary Functions | Searches a string for all occurrences |
| **REGEXP_INSTR** | Character and Binary Functions | Searches a string using a regular ex position of the substring that match |
| **REGEXP_REPLACE** | Character and Binary Functions | Searches a string for all occurrences |
| **REGEXP_SUBSTR** | Character and Binary Functions | Returns one substring from a string |
| **RELU** | Math Functions | Returns the rectified linear unit func |
| **REPEAT** | Character and Binary Functions | Repeats the character value char a |
| **REPLACE** | Character and Binary Functions | Replaces all occurrences of `substr_` |
| **REVERSE** | Character and Binary Functions | Reverse the input string. |
| **RIGHT** | Character and Binary Functions | Return the number of trailing charac |
| **RIGHT_SHIFT** | Math Functions | Returns x shifted to the right by y bi |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ROUND** | Date and Time Functions | Returns the specified date or timest |
| **ROUND** | Math Functions | Returns x rounded to the nearest int |
| **ROW_NUMBER** | Window Aggregate Functions | Assigns a unique number to each ro |
| **RPAD** | Character and Binary Functions | Pad the input text to the specified le |
| **RSUBSTRING** | Character and Binary Functions | Returns the substring from the right |
| **RTRIM** | Character and Binary Functions | Removes leading blanks from the st |
| **SECOND** | Date and Time Functions | Extracts the seconds portion of a tin |
| **SECONDS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **SHA1** | Character and Binary Functions | Uses the [SHA-1](**https://en.wikipe 1#:~:text=In%20cryptography%** cryptographic hash function to conv 160-bit checksum. |
| **SHOW** | System Functions | The SHOW function enables you to e |
| **SIGN** | Math Functions | Returns the positive (+1), zero (0), c |
| **SIN** | Math Functions | Returns the sine of x. |
| **SINH** | Math Functions | Returns the hyperbolic sine of x. |
| **SKEW** | Aggregate Functions | The sample over the set. |
| **SKEWP** | Aggregate Functions | Computes the population skewness |
| **SMALLINT** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **SOFTMAX** | Array Functions | Returns the softmax of the array. |
| **SOFTMAX** | Matrix Functions | Returns the softmax of a one-dimen |
| **SPACE** | Character and Binary Functions | Returns a string of repeated spaces |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **SPLIT_PART** | Character and Binary Functions | Split the value string based on the d the index value (starting from 1). |
| **SPLIT_TO_ARRAY** | Character and Binary Functions | Splits a string into an array of substı |
| **SQRT** | Math Functions | Returns the square root of x. |
| **SQUARE** | Math Functions | Returns the square of x. |
| **ST_ADDPOINT** | Geospatial Linestring Function | Adds a POINT to the given LINESTRI |
| **ST_ANGLE** | Geospatial Spatial Measurement | Calculates the angle between two li |
| **ST_AREA** | Geospatial Spatial Measurement | Returns the area of the specified ge |
| **ST_ASBINARY** | Geospatial Conversion Functions | Returns the well-known binary (WKE |
| **ST_ASEWKT** | Geospatial Conversion Functions | Returns a string that represents geo |
| **ST_ASGEOJSON** | Geospatial Conversion Functions | Alias of ST_ASBINARY. |
| **ST_ASLATLONTEXT** | Geospatial Conversion Functions | **Returns the GeoJSON represent** |
| **ST_ASTEXT** | Geospatial Conversion Functions | Alias of ST_ASTEXT. |
| **ST_ASWKB** | Geospatial Conversion Functions | Alias of ST_ASTEXT. |
| **ST_ASWKT** | Geospatial Conversion Functions | Alias of ST_ASWKT and ST_EWKT. Re |
| **ST_AZIMUTH** | Geospatial Spatial Measurement | Returns the azimuth of the line from |
| **ST_BOUNDINGDIAGONAL** | Geospatial Spatial Operators | Returns the diagonal LINESTRING fr ST_ENVELOPE returns. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_BUFFER** | Geospatial Spatial Operators | Returns a geography that contains a specified distance. |
| **ST_CENTROID** | Geospatial Point Constructors | The geographic center of mass is ca projecting the resultant point onto tl |
| **ST_CLOSESTPOINT** | Geospatial Spatial Operators | Returns the two-dimensional POINT object. |
| **ST_CLUSTERDBSCAN** | Geospatial Spatial Relationships | **Returns the cluster number for the density-based spatial cluste** |
| **ST_CONTAINS** | Geospatial Spatial Relationships | Returns TRUE if the first geographic |
| **ST_CONTAINSPROPERLY** | Geospatial Spatial Relationships | Returns true if geo2 lies entirely in t points. |
| **ST_CONVEXHULL** | Geospatial Spatial Operators | The convex hull is the smallest conv |
| **ST_COORDDIM** | Geospatial Attribute Functions | ST_NDIMS and ST_NDIMENSION are specified geography. |
| **ST_COVEREDBY** | Geospatial Spatial Relationships | Returns TRUE if no POINT in geo1 is |
| **ST_COVERS** | Geospatial Spatial Relationships | Returns TRUE if no POINT in geo2 is |
| **ST_CROSSES** | Geospatial Spatial Relationships | Returns TRUE if two geospatial obje The intersection is not equal to geo1 |
| **ST_DIFFERENCEARRAY** | Geospatial Spatial Operators | Returns an array containing any geo not found in the second geospatial a |
| **ST_DIMENSION** | Geospatial Attribute Functions | Returns an INTEGER that represents |
| **ST_DISJOINT** | Geospatial Spatial Relationships | Returns true if the specified geograp be different types. |
| **ST_DISTANCE** | Geospatial Spatial Measurement | Returns the minimum distance betw |
| **ST_DISTANCE** | Geospatial Spatiotemporal Measurement | Returns the two-dimensional interpo array pairs in the specified unit of m |
| **ST_DISTANCESPHERE** | Geospatial Spatial Measurement | Returns the minimum distance betw |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_DISTANCESPHEROID** | Geospatial Spatial Measurement | Returns the minimum distance betw |
| **ST_DWITHIN** | Geospatial Spatial Relationships | Returns TRUE if the geographies are |
| **ST_ENDPOINT** | Geospatial Linestring Function | Returns the endpoint of a specified l |
| **ST_ENVELOPE** | Geospatial Spatial Operators | Returns a POLYGON that represents |
| **ST_EQUALS** | Geospatial Spatial Relationships | Returns TRUE if both geographies ar |
| **ST_EUCLIDEANDISTANCE3D** | Geospatial Spatial Measurement | Returns the minimum distance betw |
| **ST_EXPAND** | Geospatial Spatial Operators | Returns the bounding box of a speci |
| **ST_EXTERIORRING** | Geospatial Spatial Operators | Returns a LINESTRING that represen |
| **ST_FLIPCOORDINATES** | Geospatial Spatial Operators | Returns a new geographic object wit |
| **ST_FORCE2D** | Geospatial Spatial Operators | Convert a geographic object into a t |
| **ST_FORCECCW** | Geospatial Polygon Constructors | Creates a standardized polygon fron counterclockwise (CCW) and all hole |
| **ST_GEOGPOINT** | Geospatial Point Constructors | Creates and returns a POLYGON geo function. |
| **ST_GEOHASH** | Geospatial Conversion Functions | Returns a string that represents the |
| **ST_GEOMETRYTYPE** | Geospatial Attribute Functions | Returns a string representing the ge |
| **ST_HAUSDORFFDISTANCE** | Geospatial Spatial Measurement | Returns the Hausdorff distance betw |
| **ST_INTERIORRINGN** | Geospatial Spatial Operators | Returns a LINESTRING representing indexed) |
| **ST_INTERSECTALL** | Geospatial Spatial Operators | Returns the intersection of all geogr |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_INTERSECTION** | Geospatial Spatiotemporal Operators | Returns a tuple that represents the i |
| **ST_INTERSECTIONARRAY** | Geospatial Spatial Operators | Returns a geography that represents |
| **ST_INTERSECTS** | Geospatial Spatial Relationships | Returns TRUE if the specified geogra |
| **ST_ISCCW** | Geospatial Spatial Relationships | Alias for ST_ISPOLYGONCCW. |
| **ST_ISCLOSED** | Geospatial Spatial Relationships | Returns TRUE if an input POLYGON h |
| **ST_ISEMPTY** | Geospatial Attribute Functions | Returns TRUE if the specified geogra |
| **ST_ISPOLYGONCCW** | Geospatial Spatial Relationships | Returns TRUE if an input LINESTRING |
| **ST_ISPOLYGONCW** | Geospatial Spatial Relationships | Returns TRUE if an input POLYGON h |
| **ST_ISRING** | Geospatial Spatial Relationships | Returns TRUE if the specified LINEST |
| **ST_ISSIMPLE** | Geospatial Spatial Relationships | For LINESTRING values, this functior For POLYGON values, the function re |
| **ST_ISVALID** | Geospatial Spatial Relationships | **Returns TRUE if the specified ge OGC standards.** |
| **ST_LENGTH** | Geospatial Spatial Measurement | Returns the length of the specified l |
| **ST_LENGTH2D** | Geospatial Spatial Measurement | Alias for ST_LENGTH. |
| **ST_LINEFROMEWKT** | Geospatial Linestring Constructor | Creates a LINESTRING from the spec |
| **ST_LINEFROMGEOJSON** | Geospatial Linestring Constructor | Creates a LINESTRING represented b |
| **ST_LINEFROMTEXT** | Geospatial Linestring Constructor | Creates a LINESTRING from a specifi |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_LINEFROMWKB** | Geospatial Linestring Constructor | Creates a LINESTRING from the spec |
| **ST_LINEGETALLTIMESATPOINT** | Geospatial Spatiotemporal Operators | Returns a timestamp array of all tim |
| **ST_LINEGETPOINTATTIME** | Geospatial Spatiotemporal Operators | Returns a POINT within the bounds c specified TIMESTAMP value. |
| **ST_LINEGETTIMEATPOINT** | Geospatial Spatiotemporal Operators | Returns the interpolated time of the ARRAY. |
| **ST_LINEINTERPOLATEPOINT** | Geospatial Linestring Function | Returns a POINT along a LINESTRINC |
| **ST_LINELOCATEPOINT** | Geospatial Linestring Function | Similar to ST_LINEINTERPOLATEPOIN along the length of a specified LINES |
| **ST_LINESTRING** | Geospatial Linestring Constructor | Creates a LINESTRING based on the |
| **ST_LINESUBSTRING** | Geospatial Linestring Function | Returns a LINESTRING that is a subs length. |
| **ST_LONGESTLINE** | Geospatial Spatial Operators | Returns the longest LINESTRING bet |
| **ST_LONGESTLINE** | Geospatial Spatiotemporal Operators | With the specified two LINESTRING-T represents the maximum distance b |
| **ST_MAKEENVELOPE** | Geospatial Spatial Operators | Returns a POLYGON with vertices tha |
| **ST_MAKELINE** | Geospatial Linestring Constructor | Alias for ST_LINESTRING. |
| **ST_MAKEPOINT** | Geospatial Point Constructors | Alias for ST_POINT. |
| **ST_MAKEPOLYGON** | Geospatial Polygon Constructors | Alias for ST_POLYGON. |
| **ST_MAXDISTANCE** | Geospatial Spatial Measurement | Returns maximum distance betweer |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_MAXDISTANCE** | Geospatial Spatiotemporal Measurement | Returns the two-dimensional interpc pairs in the specified unit of measur |
| **ST_MEMSIZE** | Geospatial Attribute Functions | Returns an INTEGER representing th |
| **ST_MINIMUMBOUNDINGCIRCLE** | Geospatial Spatial Operators | Returns the smallest circle POLYGON |
| **ST_MULTIDIFFERENCEARRAY** | Geospatial Spatial Operators | Returns an array of geographies tha not intersect with the union of geog |
| **ST_MINIMUMDISTANCETOSURFACE** | Geospatial Spatial Measurement | Calculates the shortest distance bet the surface of the Earth. |
| **ST_MULTIINTERSECTIONARRAY** | Geospatial Spatial Operators | When you specify two arrays of geos |
| **ST_MULTISYMDIFFERENCEARRAY** | Geospatial Spatial Operators | When you specify two arrays of geos intersect. |
| **ST_MULTIUNIONARRAY** | Geospatial Spatial Operators | When you specify two arrays of geos geographies in both arrays. |
| **ST_NDIMENSION** | Geospatial Attribute Functions | Alias for ST_COORDDIM. |
| **ST_NDIMS** | Geospatial Attribute Functions | Alias for ST_COORDDIM. |
| **ST_NPOINTS** | Geospatial Attribute Functions | Returns an INTEGER representing th |
| **ST_NRINGS** | Geospatial Spatial Operators | Returns the number of rings of the s |
| **ST_NUMINTERIORRING** | Geospatial Spatial Operators | Returns the number of interior rings |
| **ST_NUMINTERIORRINGS** | Geospatial Spatial Operators | Returns the number of interior rings |
| **ST_NUMPOINTS** | Geospatial Attribute Functions | Returns an INTEGER representing th |
| **ST_OVERLAPS** | Geospatial Spatial Relationships | Returns TRUE if both geographic arg contains the other. |
| **ST_PERIMETER** | Geospatial Spatial Measurement | Returns the length of the exterior (o |

© 2026 Ocient, Inc

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_PERIMETER2D** | Geospatial Spatial Measurement | Alias for ST_PERIMETER. |
| **ST_POINT** | Geospatial Point Constructors | Creates a POINT from the specified i |
| **ST_POINTFROMEWKT** | Geospatial Point Constructors | Alias for ST_POINT. Creates a POINT |
| **ST_POINTFROMGEOHASH** | Geospatial Point Constructors | Creates a POINT represented by the |
| **ST_POINTFROMGEOJSON** | Geospatial Point Constructors | Creates a POINT represented by the |
| **ST_POINTFROMTEXT** | Geospatial Point Constructors | Alias for ST_POINT(char). |
| **ST_POINTFROMWKB** | Geospatial Point Constructors | Alias for ST_POINT(binary). |
| **ST_POINTINSIDECIRCLE** | Geospatial Spatial Relationships | Returns TRUE if the geographic obje specified radius. |
| **ST_POINTN** | Geospatial Linestring Function | Returns the POINT value at a specifi |
| **ST_POINTONSURFACE** | Geospatial Spatial Operators | Returns a POINT guaranteed to inter |
| **ST_POLYGON** | Geospatial Polygon Constructors | Creates a POLYGON. |
| **ST_POLYGONFROMEWKT** | Geospatial Polygon Constructors | Creates a POLYGON using an EWKT-f |
| **ST_POLYGONFROMGEOJSON** | Geospatial Polygon Constructors | Creates a POLYGON from the specifi |
| **ST_POLYGONFROMTEXT** | Geospatial Polygon Constructors | Alias for ST_POLYGON(char). |
| **ST_POLYGONFROMWKB** | Geospatial Polygon Constructors | Alias for ST_POLYGON(binary). |
| **ST_PROJECT** | Geospatial Spatial Operators | Returns a POINT by projecting a dist |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_REDUCEPRECISION** | Geospatial Spatial Operators | Returns a new geospatial object witl |
| **ST_RELATE** | Geospatial Spatial Relationships | Returns the **DE-9IM** intersection str |
| **ST_REMOVEPOINT** | Geospatial Linestring Function | Removes a POINT value at a specifie |
| **ST_REMOVEREPEATEDPOINTS** | Geospatial Spatial Operators | Returns a new geospatial object witl |
| **ST_REVERSE** | Geospatial Spatial Operators | Returns a new geospatial object witl |
| **ST_SEGMENTIZE** | Geospatial Spatial Operators | Returns a geospatial object that the max_segment_length in meters. |
| **ST_SETPOINT** | Geospatial Linestring Function | Replaces a POINT value in a given L the replaced point. |
| **ST_SHORTESTLINE** | Geospatial Spatial Operators | Returns the shortest LINESTRING be |
| **ST_SHORTESTLINE** | Geospatial Spatiotemporal Operators | When you specify two LINESTRING-T represents the minimum distance b |
| **ST_SIMPLIFY** | Geospatial Spatial Operators | Returns a simplified version of the s |
| **ST_SIMPLIFYARRAY** | Geospatial Spatial Operators | Returns a POLYGON array that repre LINESTRING, or POLYGON. |
| **ST_SNAPTOGRID** | Geospatial Spatial Operators | Returns a new geography value with |
| **ST_SRID** | Geospatial Attribute Functions | Returns the EPSG code of the spatia |
| **ST_STARTPOINT** | Geospatial Linestring Function | Returns the starting POINT value of |
| **ST_SYMDIFFERENCEARRAY** | Geospatial Spatial Operators | Returns a geographic array that con geo2. |
| **ST_TOTALSECONDSININTERSECTION** | Geospatial Spatiotemporal Measurement | Returns the total number of seconds ST_INTERSECTION. |
| **ST_TOUCHES** | Geospatial Spatial Relationships | Returns TRUE if the only POINT valu boundaries. |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_UNIONARRAY** | Geospatial Spatial Operators | Performs a union of the input geogr |
| **ST_WHOLEEARTH** | Geospatial Polygon Constructors | Returns the database internal repre |
| **ST_WITHIN** | Geospatial Spatial Relationships | Alias for ST_CONTAINS. |
| **ST_X** | Geospatial Attribute Functions | Returns the x value of the specified |
| **ST_XMAX** | Geospatial Attribute Functions | Returns the maximum x value of the |
| **ST_XMIN** | Geospatial Attribute Functions | Returns the minimum x value of the |
| **ST_Y** | Geospatial Attribute Functions | Returns the y value of the specified |
| **ST_YMAX** | Geospatial Attribute Functions | Returns the maximum y value of spe |
| **ST_YMIN** | Geospatial Attribute Functions | Returns the minimum y value of spe |
| **STARTSWITH** | Character and Binary Functions | Returns true if string starts with sub |
| **STDEV** | Aggregate Functions | Sample standard deviation. |
| **STDDEV** | Aggregate Functions | Alias for STDEV. |
| **STDDEV_POP** | Aggregate Functions | Alias for STDEVP. |
| **STDDEV_SAMP** | Aggregate Functions | Alias for STDEV. |
| **STDEVP** | Aggregate Functions | Population standard deviation. |
| **STRING_AGG** | Aggregate Functions | Returns a string concatenated from |
| **STRING_TO_ARRAY** | Array Functions | Converts the string representation c |
| **STRING_TO_TUPLE** | Tuple Functions | Converts the string representation c |

| Function Name | Category Name | Function Description |
|---|---|---|
| **STRPOS** | Character and Binary Functions | Equivalent to using LOCATE as `LOCA` |
| **SUBSTR** | Character and Binary Functions | Alias for SUBSTRING. |
| **SUBSTRING** | Character and Binary Functions | Returns the substring of a character |
| **SUBNET** | Network Type Functions | Computes the prefix from an `IP` or |
| **SUM** | Aggregate Functions | Sum over the set. |
| **SVD_DECOMP** | Matrix Functions | Returns SVD decomposition of a ma |
| **TAN** | Math Functions | Returns the tangent of x. |
| **TANH** | Math Functions | Returns the hyperbolic tangent of x. |
| **TIME** | Scalar Data Conversion Functions | Parses the string to create a time va |
| **TIMESTAMP** | Scalar Data Conversion Functions | Parses a string and makes a timesta |
| **TIMESTAMP_TO_NANOS** | Date and Time Functions | Convert timestamp into nanosecond |
| **TO_ARRAY_LENGTH** | Special Data Pipeline Transformation Functions | Create the specified number of copi |
| **TO_BASE** | Math Functions | Converts an integer value to its strir |
| **TO_CHAR** | Character and Binary Functions | Converts a numeric, date, or timesta |
| **TO_DATE** | Formatting Functions | Converts a character value with the |
| **TO_NUMBER** | Formatting Functions | Converts a character value with the |
| **TO_TIMESTAMP** | Formatting Functions | Converts a character value with the |
| **TRANSFORM** | Special Data Pipeline | Transforms an array based on the lo |

| Function Name | Category Name | Function Description |
|---|---|---|
| | Transformation Functions | |
| **TRANSLATE** | Character and Binary Functions | Replaces specified characters in a p |
| **TRANSPOSE** | Matrix Functions | Returns transpose of the matrix. |
| **TRIM** | Character and Binary Functions | Alias for BTRIM. Trim leading and tra |
| **TRUNC** | Math Functions | Returns x truncated to y decimal pla |
| **TRUNCATE** | Math Functions | Alias for TRUNC. |
| **TUPLE()** | Tuple Functions | Construct a tuple with the specified |
| **TUPLE<<>>** | Tuple Functions | Construct a tuple with the specified |
| **TYPE[]** | Array Functions | Construct an array of SQL type TYPE |
| **TYPE_STRIP** | Other Functions and Expressions | Returns the SQL type of the specifie |
| **UCASE** | Character and Binary Functions | Alias for UPPER. |
| **UNNEST** | Array Functions | Expand each element in an input arı |
| **UPPER** | Character and Binary Functions | Convert string to upper case. |
| **USECS** | Date and Time Functions | The seconds part of a time value, in seconds part of the value by 1,000,( |
| **UUID** | Scalar Data Conversion Functions | Parses the string and makes a Unive |
| **UUID_GENERATE** | Other Functions and Expressions | Generates a random UUID value (ve |
| **VAR_POP** | Aggregate Functions | Alias for VARIANCEP. |
| **VAR_SAMP** | Aggregate Functions | Alias for VARIANCE. |
| **VARIANCE** | Aggregate Functions | Sample variance. |
| **VARIANCEP** | Aggregate Functions | Population variance. |

| Function Name | Category Name | Function Description |
|---|---|---|
| **VECTOR_ARGMAX** | Matrix Functions | Returns the argmax of a one-dimens |
| **VECTOR_ARGMIN** | Matrix Functions | Returns the argmin of a one-dimens |
| **VECTOR_MAX** | Matrix Functions | Returns the maximum of elements i |
| **VECTOR_MIN** | Matrix Functions | Returns the minimum of elements ir |
| **VECTOR_SUM** | Matrix Functions | Returns the sum of elements in a or |
| **VERSION** | System Functions | Returns the version of the database |
| **WEEK** | Date and Time Functions | Returns the ISO-8601 week number |
| **WEEKS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **WIDTH_BUCKET** | Special Data Pipeline Transformation Functions | Creates `N` equal-width buckets in t |
| **YEAR** | Date and Time Functions | Extracts the year portion of a timest |
| **YEARS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **ZERO_MATRIX** | Matrix Functions | Returns a zero matrix of the specifie |
| **ZIP_WITH** | Special Data Pipeline Transformation Functions | Merges two or more input arrays, el |
| **ZIP_WITH_ORD** | Array Functions | Merges two or more input arrays, el 1-based ordinal of each tuple. |
| **ZN** | Conditional Functions | If x is NULL, returns 0. Otherwise, re |
| **ZSCORE** | Window Aggregate Functions | Zscore of the sample based on the |
| **ZSCOREP** | Window Aggregate Functions | Zscore of the sample based on the |

# Categorized SQL Functions List

Categorized reference of Ocient SQL functions grouped by purpose, including aggregate, conversion, date and time, math, string, spatial, and machine learning.

| Function Name | Category Name | Function Description |
|---|---|---|
| ACCURACY_SCORE | Aggregate Functions | Returns the fraction of predictions th |
| ANY_VALUE | Aggregate Functions | Returns an arbitrary, non-NULL valu |
| APPROX_COUNT_DISTINCT | Aggregate Functions | Approximate distinct count by using |
| APPROX_SUM | Aggregate Functions | Allows the aggregation engine to us |
| ARRAY_AGG | Aggregate Functions | Returns an array containing every ro |
| ARRAY_CONCAT_AGG | Aggregate Functions | Returns an array that concatenates |
| AVG | Aggregate Functions | Average, or arithmetic mean, over t |
| COEFFICIENT_OF_DETERMINATION | Aggregate Functions | Computes the coefficient of determi |
| CONFUSION_MATRIX | Aggregate Functions | Returns a structured representation to a specified positive class. |
| CORR | Aggregate Functions | Alias for CORRELATION. |
| CORRELATION | Aggregate Functions | Sample correlation. |
| CORRELATIONP | Aggregate Functions | Population correlation. |
| COUNT | Aggregate Functions | Number of rows in the set. |
| COVAR_POP | Aggregate Functions | Alias for COVARIANCEP. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **COVAR_SAMP** | Aggregate Functions | Alias for COVARIANCE. |
| **COVARIANCE** | Aggregate Functions | Sample covariance. |
| **COVARIANCEP** | Aggregate Functions | Population covariance. |
| **F1_SCORE** | Aggregate Functions | Returns the harmonic mean of preci |
| **KURTOSIS** | Aggregate Functions | The sample over the set. |
| **KURTOSISP** | Aggregate Functions | The population over the set. |
| **MAX** | Aggregate Functions | Maximum value in the specified colu |
| **MEAN_ABSOLUTE_ERROR** | Aggregate Functions | Returns the mean absolute error (MA |
| **MEAN_ABSOLUTE_PERCENTAGE_ERROR** | Aggregate Functions | Returns the mean absolute percenta |
| **MIN** | Aggregate Functions | Minimum value in the specified colu |
| **PRECISION_SCORE** | Aggregate Functions | Returns the precision score for a spe |
| **PRODUCT** | Aggregate Functions | Product over the set. |
| **RECALL_SCORE** | Aggregate Functions | Returns the recall score for a specifi |
| **ROC_AUC_SCORE** | Aggregate Functions | Returns the area under the receiver |
| **SKEW** | Aggregate Functions | The sample skewness over the set o |
| **SKEWP** | Aggregate Functions | Computes the population skewness |
| **STDEV** | Aggregate Functions | Sample standard deviation. |
| **STDDEV** | Aggregate Functions | Alias for STDEV. |

| Function Name | Category Name | Function Description |
|---|---|---|
| **STDDEV_POP** | Aggregate Functions | Alias for STDEVP. |
| **STDDEV_SAMP** | Aggregate Functions | Alias for STDEV. |
| **STDEVP** | Aggregate Functions | Population standard deviation. |
| **STRING_AGG** | Aggregate Functions | Returns a string concatenated from |
| **SUM** | Aggregate Functions | Sum over the set. |
| **VAR_POP** | Aggregate Functions | Alias for VARIANCEP. |
| **VAR_SAMP** | Aggregate Functions | Alias for VARIANCE. |
| **VARIANCE** | Aggregate Functions | Sample variance. |
| **VARIANCEP** | Aggregate Functions | Population variance. |
| **ARRAY[]** | Array Functions | PostgreSQL®-compliant constructor |
| **ARRAY_APPEND** | Array Functions | Add value to the back of an array. |
| **ARRAY_ARGMAX** | Array Functions | Returns the corresponding argmax c |
| **ARRAY_ARGMIN** | Array Functions | Returns the corresponding argmin o |
| **ARRAY_CAT** | Array Functions | Concatenate 2 arrays into a new on |
| **ARRAY_CAT_DISTINCT** | Array Functions | Concatenates two or more arrays in |
| **ARRAY_DISTINCT** | Array Functions | Removes duplicates from an array w |
| **ARRAY_INTERSECT_DISTINCT_COUNT** | Array Functions | Returns the count of distinct elemer |
| **ARRAY_LENGTH** | Array Functions | Return the number of elements of a |
| **ARRAY_MAX** | Array Functions | Returns the corresponding maximur |
| **ARRAY_MIN** | Array Functions | Returns the corresponding minimum |
| **ARRAY_POSITION** | Array Functions | Returns the position of the first mat |
| **ARRAY_POSITIONS** | Array Functions | Returns all elements stored in the ri |
| **ARRAY_PREPEND** | Array Functions | Add value to the front of an array. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **ARRAY_REMOVE** | Array Functions | Remove value from the array. |
| **ARRAY_REPLACE** | Array Functions | Replace value by another in an arra |
| **ARRAY_SUM** | Array Functions | Returns the sum of the array. The ar contribute to the sum. |
| **ARRAY_TO_STRING** | Array Functions | Converts array to a list of elements |
| **ARRAY_TRANSFORM** | Array Functions | Transforms one or more arrays using element-wise. |
| **ARRAY_TRANSFORM_WITH_ORD** | Array Functions | Transforms an array using a lambda |
| **CAST_TO_ARRAY** | Array Functions | Casts the elements of the array to a |
| **CHAR** | Array Functions | Converts array to its string represen |
| **CROSS_ENTROPY_LOSS** | Array Functions | Returns the cross entropy loss of tw |
| **HINGE_LOSS** | Array Functions | Returns the hinge loss of two arrays |
| **JACCARD_SIMILARITY** | Array Functions | Returns the Jaccard similarity coeffic |
| **LOG_LOSS** | Array Functions | Returns the log loss of two arrays. |
| **LOGITS_LOSS** | Array Functions | Returns the logits loss of two arrays |
| **SOFTMAX** | Array Functions | Returns the softmax of the array. |
| **STRING_TO_ARRAY** | Array Functions | Converts the string representation c |
| **TYPE[]** | Array Functions | Construct an array of SQL type TYPE |
| **UNNEST** | Array Functions | Expand each element in an input ar |
| **ZIP_WITH_ORD** | Array Functions | Merges two or more input arrays, el 1-based ordinal of each tuple. |
| **ASCII** | Character and Binary Functions | Returns the ASCII code value of the |
| **BIT_LENGTH** | Character and Binary Functions | Returns the length of the character |
| **BTRIM** | Character and Binary Functions | Alias for TRIM. |
| **CHAR_LENGTH** | Character and Binary Functions | Alias for LENGTH. |
| **CHARACTER_LENGTH** | Character and Binary Functions | Alias for LENGTH. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **CHR** | Character and Binary Functions | Converts an integer value to a string |
| **CONCAT** | Character and Binary Functions | Concatenates two values, which mu the \|\| operator. |
| **ENDSWITH** | Character and Binary Functions | Returns true if x ends with y and fals |
| **INITCAP** | Character and Binary Functions | For each word in the provided string |
| **INSTR** | Character and Binary Functions | Returns the index position of the firs value char by ignoring the case. |
| **JSON_EXTRACT_PATH_TEXT** | Character and Binary Functions | Returns the value for the key-value |
| **LCASE** | Character and Binary Functions | Alias for LOWER. |
| **LEFT** | Character and Binary Functions | Return the number of characters in returns all but the last integer chara |
| **LENGTH** | Character and Binary Functions | For character data types, this value |
| **LOCATE** | Character and Binary Functions | Alias for POSITION. Returns the inde value string. |
| **LOWER** | Character and Binary Functions | Alias for LCASE. Convert string to lo |
| **LPAD** | Character and Binary Functions | Pad the input text to the specified le |
| **LTRIM** | Character and Binary Functions | Removes leading blanks from the st |
| **MD5** | Character and Binary Functions | Returns the hexadecimal string (all l |
| **MID** | Character and Binary Functions | Alias for SUBSTRING. |
| **OCTET_LENGTH** | Character and Binary Functions | Returns the length in bytes of a cha |
| **POSITION** | Character and Binary Functions | Alias for LOCATE. |
| **REGEXP_COUNT** | Character and Binary Functions | Searches a string for all occurrences |

| Function Name | Category Name | Function Description |
|---|---|---|
| **REGEXP_INSTR** | Character and Binary Functions | Searches a string using a regular ex position of the substring that match |
| **REGEXP_REPLACE** | Character and Binary Functions | Searches a string for all occurrences |
| **REGEXP_SUBSTR** | Character and Binary Functions | Returns one substring from a string |
| **REPEAT** | Character and Binary Functions | Repeats the character value char a |
| **REPLACE** | Character and Binary Functions | Replaces all occurrences of substr_t |
| **REVERSE** | Character and Binary Functions | Reverse the input string. |
| **RIGHT** | Character and Binary Functions | Return the number of trailing charac |
| **RPAD** | Character and Binary Functions | Pad the input text to the specified le |
| **RSUBSTRING** | Character and Binary Functions | Returns the substring from the right |
| **RTRIM** | Character and Binary Functions | Removes leading blanks from the st |
| **SHA1** | Character and Binary Functions | Uses the [SHA-1](**https://en.wikipe 1#:~:text=In%20cryptography%** cryptographic hash function to conv 160-bit checksum. |
| **SPACE** | Character and Binary Functions | Returns a string of repeated spaces |
| **SPLIT_PART** | Character and Binary Functions | Split the value string based on the d the index value (starting from 1). |
| **SPLIT_TO_ARRAY** | Character and Binary Functions | Splits a string into an array of substr |
| **STARTSWITH** | Character and Binary Functions | Returns true if string starts with sub |
| **STRPOS** | Character and Binary Functions | Equivalent to using LOCATE as LOCA |
| **SUBSTR** | Character and Binary Functions | Alias for SUBSTRING. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **SUBSTRING** | Character and Binary Functions | Returns the substring of a character |
| **TO_CHAR** | Character and Binary Functions | Converts a numeric, date, or timest |
| **TRANSLATE** | Character and Binary Functions | Replaces specified characters in a p |
| **TRIM** | Character and Binary Functions | Alias for BTRIM. Trim leading and tra |
| **UCASE** | Character and Binary Functions | Alias for UPPER. |
| **UPPER** | Character and Binary Functions | Convert string to upper case. |
| **CASE** | Conditional Functions | CASE operates similarly to condition then / else statement or as a switch |
| **COALESCE** | Conditional Functions | Evaluates to the first argument that |
| **GREATEST** | Conditional Functions | Returns the largest non-NULL value |
| **IF_NULL** | Conditional Functions | Alias for COALESCE. |
| **LEAST** | Conditional Functions | Returns the smallest non-NULL valu |
| **MURMUR3** | Conditional Functions | **Returns a 32-bit MurmurHash3 l** |
| **NULL_IF** | Conditional Functions | Returns the NULL value if two argum |
| **ZN** | Conditional Functions | If x is NULL, returns 0. Otherwise, re |
| **LAG_VECTORS** | Data Preparation | Groups lagged columns generated b |
| **LAGS** | Data Preparation | Generates a series of lagged columr |
| **LAGS_ZEROFILL** | Data Preparation | Generates lagged columns for a sing |
| **MULTI_LAGS** | Data Preparation | Generates lagged columns for multi |
| **MULTI_LAGS_ZEROFILL** | Data Preparation | Generates lagged columns for multi |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ADD_MONTHS** | Date and Time Functions | Adds the specified number of month |
| **CENTURY** | Date and Time Functions | Returns the number of centuries. |
| **CURDATE** | Date and Time Functions | Alias for CURRENT_DATE. |
| **CURRENT_DATE** | Date and Time Functions | Returns the current date in the form |
| **CURRENT_TIME** | Date and Time Functions | Returns the current time as a TIME v |
| **CURRENT_TIMESTAMP** | Date and Time Functions | Returns the current date and time a |
| **DATE_PART** | Date and Time Functions | Alias for EXTRACT. |
| **DATE_TRUNC** | Date and Time Functions | Returns the date or timestamp ente |
| **DATEADD** | Date and Time Functions | Adds a specified number value (as a that modified value. |
| **DATEDIFF** | Date and Time Functions | This function returns an INT represe unit. |
| **DAY** | Date and Time Functions | Alias for DAY_OF_MONTH. |
| **DAY_OF_MONTH** | Date and Time Functions | Extracts the day-of-month portion of |
| **DAY_OF_WEEK** | Date and Time Functions | Returns an integer, in the range of 1 |
| **DAY_OF_YEAR** | Date and Time Functions | Returns an integer in the range 1 to |
| **DECADE** | Date and Time Functions | The decade is the year divided by 1 |
| **DOW** | Date and Time Functions | Alias for DAY_OF_WEEK. |
| **DOY** | Date and Time Functions | Alias for DAY_OF_YEAR. |
| **EOMONTH** | Date and Time Functions | Returns the last day of the timestam |

| Function Name | Category Name | Function Description |
|---|---|---|
| **EPOCH** | Date and Time Functions | The number of seconds after 1970-( |
| **EXTRACT** | Date and Time Functions | Extract a component from a timesta |
| **HOUR** | Date and Time Functions | Extracts the hour portion of a timest |
| **ISDATE** | Date and Time Functions | Returns TRUE if the input argument |
| **ISODOW** | Date and Time Functions | Extracts the day of the week based |
| **MAKEDATETIME** | Date and Time Functions | Returns a timestamp consisting of th |
| **MILLISECOND** | Date and Time Functions | Extracts the millisecond portion of a |
| **MINUTE** | Date and Time Functions | Extracts the minute portion of a tim |
| **MONTH** | Date and Time Functions | Extracts the month portion of a time |
| **MONTH_NAME** | Date and Time Functions | Returns the calendar name in Englis |
| **MONTHS_BETWEEN** | Date and Time Functions | Returns the difference between the |
| **MSECS** | Date and Time Functions | The seconds field, including fraction |
| **NANOS_TO_TIMESTAMP** | Date and Time Functions | Convert a number of nanoseconds in |
| **NEXT_DAY** | Date and Time Functions | Returns the closest date after a spec |
| **NOW** | Date and Time Functions | Alias for CURRENT_TIMESTAMP. |
| **QUARTER** | Date and Time Functions | Returns an integer between 1 and 4 |
| **ROUND** | Date and Time Functions | Returns the specified date or timest |
| **SECOND** | Date and Time Functions | Extracts the seconds portion of a tin |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **TIMESTAMP_TO_NANOS** | Date and Time Functions | Convert timestamp into nanosecond |
| **USECS** | Date and Time Functions | The seconds part of a time value, in seconds part of the value by 1,000,( |
| **WEEK** | Date and Time Functions | Returns the ISO-8601 week number, |
| **YEAR** | Date and Time Functions | Extracts the year portion of a timest |
| **TO_DATE** | Formatting Functions | Converts a character value with the |
| **TO_NUMBER** | Formatting Functions | Converts a character value with the |
| **TO_TIMESTAMP** | Formatting Functions | Converts a character value with the |
| **ST_COORDDIM** | Geospatial Attribute Functions | ST_NDIMS and ST_NDIMENSION are specified geography. |
| **ST_DIMENSION** | Geospatial Attribute Functions | Returns an INTEGER that represents |
| **ST_GEOMETRYTYPE** | Geospatial Attribute Functions | Returns a string representing the ge |
| **ST_ISEMPTY** | Geospatial Attribute Functions | Returns TRUE if the specified geogra |
| **ST_MEMSIZE** | Geospatial Attribute Functions | Returns an INTEGER representing th |
| **ST_NDIMENSION** | Geospatial Attribute Functions | Alias for ST_COORDDIM. |
| **ST_NDIMS** | Geospatial Attribute Functions | Alias for ST_COORDDIM. |
| **ST_NPOINTS** | Geospatial Attribute Functions | Returns an INTEGER representing th |
| **ST_NUMPOINTS** | Geospatial Attribute Functions | Returns an INTEGER representing th |
| **ST_SRID** | Geospatial Attribute Functions | Returns the EPSG code of the spatia |
| **ST_X** | Geospatial Attribute Functions | Returns the x value of the specified |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_XMAX** | Geospatial Attribute Functions | Returns the maximum x value of the |
| **ST_XMIN** | Geospatial Attribute Functions | Returns the minimum x value of the |
| **ST_Y** | Geospatial Attribute Functions | Returns the y value of the specified |
| **ST_YMAX** | Geospatial Attribute Functions | Returns the maximum y value of spe |
| **ST_YMIN** | Geospatial Attribute Functions | Returns the minimum y value of spe |
| **ST_ASBINARY** | Geospatial Conversion Functions | Returns the well-known binary (WKB |
| **ST_ASEWKT** | Geospatial Conversion Functions | Returns a string that represents geo |
| **ST_ASGEOJSON** | Geospatial Conversion Functions | Alias of ST_ASBINARY. |
| **ST_ASLATLONTEXT** | Geospatial Conversion Functions | **Returns the GeoJSON representa** |
| **ST_ASTEXT** | Geospatial Conversion Functions | Alias of ST_ASTEXT. |
| **ST_ASWKB** | Geospatial Conversion Functions | Alias of ST_ASTEXT. |
| **ST_ASWKT** | Geospatial Conversion Functions | Alias of ST_ASWKT and ST_EWKT. Re |
| **ST_GEOHASH** | Geospatial Conversion Functions | Returns a string that represents the |
| **ST_ADDPOINT** | Geospatial Linestring Function | Adds a POINT to the specified LINES |
| **ST_ENDPOINT** | Geospatial Linestring Function | Returns the endpoint of a specified l |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_LINEINTERPOLATEPOINT** | Geospatial Linestring Function | Returns a POINT along a LINESTRING |
| **ST_LINELOCATEPOINT** | Geospatial Linestring Function | Similar to ST_LINEINTERPOLATEPOIN along the length of a specified LINES |
| **ST_LINESUBSTRING** | Geospatial Linestring Function | Returns a LINESTRING that is a subs length. |
| **ST_POINTN** | Geospatial Linestring Function | Returns the POINT value at a specifi |
| **ST_REMOVEPOINT** | Geospatial Linestring Function | Removes a POINT value at a specifie |
| **ST_SETPOINT** | Geospatial Linestring Function | Replaces a POINT value in a specifie with the replaced point. |
| **ST_STARTPOINT** | Geospatial Linestring Function | Returns the starting POINT value of |
| **ST_LINEFROMEWKT** | Geospatial Linestring Constructor | Creates a LINESTRING from the spec |
| **ST_LINEFROMGEOJSON** | Geospatial Linestring Constructor | Creates a LINESTRING represented b |
| **ST_LINEFROMTEXT** | Geospatial Linestring Constructor | Creates a LINESTRING from a specifi |
| **ST_LINEFROMWKB** | Geospatial Linestring Constructor | Creates a LINESTRING from the spec |
| **ST_LINESTRING** | Geospatial Linestring Constructor | Creates a LINESTRING based on the |
| **ST_MAKELINE** | Geospatial Linestring Constructor | Alias for ST_LINESTRING. |
| **ST_CENTROID** | Geospatial Point Constructors | The geographic center of mass is ca projecting the resultant point onto th |
| **ST_GEOGPOINT** | Geospatial Point Constructors | Creates and returns a POLYGON geo function. |
| **ST_MAKEPOINT** | Geospatial Point Constructors | Alias for ST_POINT. |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_POINT** | Geospatial Point Constructors | Creates a POINT from the specified i |
| **ST_POINTFROMEWKT** | Geospatial Point Constructors | Alias for ST_POINT. Creates a POINT |
| **ST_POINTFROMGEOHASH** | Geospatial Point Constructors | Creates a POINT represented by the |
| **ST_POINTFROMGEOJSON** | Geospatial Point Constructors | Creates a POINT represented by the |
| **ST_POINTFROMTEXT** | Geospatial Point Constructors | Alias for ST_POINT(char). |
| **ST_POINTFROMWKB** | Geospatial Point Constructors | Alias for ST_POINT(binary). |
| **ST_FORCECCW** | Geospatial Polygon Constructors | Creates a standardized polygon fron counterclockwise (CCW) and all hole |
| **ST_MAKEPOLYGON** | Geospatial Polygon Constructors | Alias for ST_POLYGON. |
| **ST_POLYGON** | Geospatial Polygon Constructors | Creates a POLYGON. |
| **ST_POLYGONFROMEWKT** | Geospatial Polygon Constructors | Creates a POLYGON using an EWKT-f |
| **ST_POLYGONFROMGEOJSON** | Geospatial Polygon Constructors | Creates a POLYGON from the specifi |
| **ST_POLYGONFROMTEXT** | Geospatial Polygon Constructors | Alias for ST_POLYGON(char). |
| **ST_POLYGONFROMWKB** | Geospatial Polygon Constructors | Alias for ST_POLYGON(binary). |
| **ST_WHOLEEARTH** | Geospatial Polygon Constructors | Returns the database internal repres |
| **ST_ANGLE** | Geospatial Spatial Measurement | Calculates the angle between two li |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_AREA** | Geospatial Spatial Measurement | Returns the area of the specified ge |
| **ST_AZIMUTH** | Geospatial Spatial Measurement | Returns the azimuth of the line from |
| **ST_DISTANCE** | Geospatial Spatial Measurement | Returns the minimum distance betw |
| **ST_DISTANCESPHERE** | Geospatial Spatial Measurement | Returns the minimum distance betw |
| **ST_DISTANCESPHEROID** | Geospatial Spatial Measurement | Returns the minimum distance betw |
| **ST_EUCLIDEANDISTANCE3D** | Geospatial Spatial Measurement | Returns the minimum distance betw |
| **ST_HAUSDORFFDISTANCE** | Geospatial Spatial Measurement | Returns the Hausdorff distance betw |
| **ST_LENGTH** | Geospatial Spatial Measurement | Returns the length of the specified l |
| **ST_LENGTH2D** | Geospatial Spatial Measurement | Alias for ST_LENGTH. |
| **ST_MAXDISTANCE** | Geospatial Spatial Measurement | Returns maximum distance betweer |
| **ST_MINIMUMDISTANCETOSURFACE** | Geospatial Spatial Measurement | Calculates the shortest distance bet the surface of the Earth. |
| **ST_PERIMETER** | Geospatial Spatial Measurement | Returns the length of the exterior (o |
| **ST_PERIMETER2D** | Geospatial Spatial Measurement | Alias for ST_PERIMETER. |
| **ST_BOUNDINGDIAGONAL** | Geospatial Spatial Operators | Returns the diagonal LINESTRING fr ST_ENVELOPE returns. |
| **ST_BUFFER** | Geospatial Spatial Operators | Returns a geography that contains a specified distance. |
| **ST_CLOSESTPOINT** | Geospatial Spatial Operators | Returns the two-dimensional POINT object. |
| **ST_CONVEXHULL** | Geospatial Spatial Operators | The convex hull is the smallest conv |
| **ST_DIFFERENCEARRAY** | Geospatial Spatial Operators | Returns an array containing any geo not found in the second geospatial a |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_ENVELOPE** | Geospatial Spatial Operators | Returns a POLYGON that represents |
| **ST_EXPAND** | Geospatial Spatial Operators | Returns the bounding box of a speci |
| **ST_EXTERIORRING** | Geospatial Spatial Operators | Returns a LINESTRING that represen |
| **ST_FLIPCOORDINATES** | Geospatial Spatial Operators | Returns a new geographic object wi |
| **ST_FORCE2D** | Geospatial Spatial Operators | Convert a geographic object into a t |
| **ST_INTERIORRINGN** | Geospatial Spatial Operators | Returns a LINESTRING representing indexed) |
| **ST_INTERSECTALL** | Geospatial Spatial Operators | Returns the intersection of all geogr |
| **ST_INTERSECTIONARRAY** | Geospatial Spatial Operators | Returns a geography that represents |
| **ST_LONGESTLINE** | Geospatial Spatial Operators | Returns the longest LINESTRING bet |
| **ST_MAKEENVELOPE** | Geospatial Spatial Operators | Returns a POLYGON with vertices tha |
| **ST_MINIMUMBOUNDINGCIRCLE** | Geospatial Spatial Operators | Returns the smallest circle POLYGON |
| **ST_MULTIDIFFERENCEARRAY** | Geospatial Spatial Operators | Returns an array of geographies tha not intersect with the union of geog |
| **ST_MULTIINTERSECTIONARRAY** | Geospatial Spatial Operators | When you specify two arrays of geos |
| **ST_MULTISYMDIFFERENCEARRAY** | Geospatial Spatial Operators | When you specify two arrays of geos intersect. |
| **ST_MULTIUNIONARRAY** | Geospatial Spatial Operators | When you specify two arrays of geos geographies in both arrays. |
| **ST_NRINGS** | Geospatial Spatial Operators | Returns the number of rings of the s |
| **ST_NUMINTERIORRING** | Geospatial Spatial Operators | Returns the number of interior rings |
| **ST_NUMINTERIORRINGS** | Geospatial Spatial Operators | Returns the number of interior rings |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_POINTONSURFACE** | Geospatial Spatial Operators | Returns a POINT guaranteed to inter |
| **ST_PROJECT** | Geospatial Spatial Operators | Returns a POINT by projecting a dist |
| **ST_REDUCEPRECISION** | Geospatial Spatial Operators | Returns a new geospatial object witl |
| **ST_REMOVEREPEATEDPOINTS** | Geospatial Spatial Operators | Returns a new geospatial object witl |
| **ST_REVERSE** | Geospatial Spatial Operators | Returns a new geospatial object witl |
| **ST_SEGMENTIZE** | Geospatial Spatial Operators | Returns a geospatial object that the max_segment_length in meters. |
| **ST_SHORTESTLINE** | Geospatial Spatial Operators | Returns the shortest LINESTRING be |
| **ST_SIMPLIFY** | Geospatial Spatial Operators | Returns a simplified version of the s |
| **ST_SIMPLIFYARRAY** | Geospatial Spatial Operators | Returns a POLYGON array that repre LINESTRING, or POLYGON. |
| **ST_SNAPTOGRID** | Geospatial Spatial Operators | Returns a new geography value with |
| **ST_SYMDIFFERENCEARRAY** | Geospatial Spatial Operators | Returns a geographic array that con geo2. |
| **ST_UNIONARRAY** | Geospatial Spatial Operators | Performs a union of the input geogr |
| **ST_CLUSTERDBSCAN** | Geospatial Spatial Relationships | **Returns the cluster number for the density-based spatial cluste** |
| **ST_CONTAINS** | Geospatial Spatial Relationships | Returns TRUE if the first geographic |
| **ST_CONTAINSPROPERLY** | Geospatial Spatial Relationships | Returns true if geo2 lies entirely in t points. |
| **ST_COVEREDBY** | Geospatial Spatial Relationships | Returns TRUE if no POINT in geo1 is |
| **ST_COVERS** | Geospatial Spatial Relationships | Returns TRUE if no POINT in geo2 is |
| **ST_CROSSES** | Geospatial Spatial Relationships | Returns TRUE if two geospatial obje The intersection is not equal to geo1 |

| Function Name | Category Name | Function Description |
| --- | --- | --- |
| **ST_DISJOINT** | Geospatial Spatial Relationships | Returns true if the specified geograp be different types. |
| **ST_DWITHIN** | Geospatial Spatial Relationships | Returns TRUE if the geographies are |
| **ST_EQUALS** | Geospatial Spatial Relationships | Returns TRUE if both geographies ar |
| **ST_INTERSECTS** | Geospatial Spatial Relationships | Returns TRUE if the specified geogra |
| **ST_ISCCW** | Geospatial Spatial Relationships | Alias for ST_ISPOLYGONCCW. |
| **ST_ISCLOSED** | Geospatial Spatial Relationships | Returns TRUE if an input POLYGON h |
| **ST_ISPOLYGONCCW** | Geospatial Spatial Relationships | Returns TRUE if an input LINESTRING |
| **ST_ISPOLYGONCW** | Geospatial Spatial Relationships | Returns TRUE if an input POLYGON h |
| **ST_ISRING** | Geospatial Spatial Relationships | Returns TRUE if the specified LINEST |
| **ST_ISSIMPLE** | Geospatial Spatial Relationships | For LINESTRING values, this functior For POLYGON values, the function re |
| **ST_ISVALID** | Geospatial Spatial Relationships | **Returns TRUE if the specified ge OGC standards.** |
| **ST_OVERLAPS** | Geospatial Spatial Relationships | Returns TRUE if both geographic arg contains the other. |
| **ST_POINTINSIDECIRCLE** | Geospatial Spatial Relationships | Returns TRUE if the geographic obje specified radius. |
| **ST_RELATE** | Geospatial Spatial Relationships | Returns the **DE-9IM** intersection str |
| **ST_TOUCHES** | Geospatial Spatial Relationships | Returns TRUE if the only POINT valu boundaries. |
| **ST_WITHIN** | Geospatial Spatial Relationships | Alias for ST_CONTAINS. |
| **ST_DISTANCE** | Geospatial Spatiotemporal Measurement | Returns the two-dimensional interpo array pairs in the specified unit of m |

| Function Name | Category Name | Function Description |
|---|---|---|
| **ST_MAXDISTANCE** | Geospatial Spatiotemporal Measurement | Returns the two-dimensional interpc pairs in the specified unit of measur |
| **ST_TOTALSECONDSININTERSECTION** | Geospatial Spatiotemporal Measurement | Returns the total number of seconds ST_INTERSECTION. |
| **ST_INTERSECTION** | Geospatial Spatiotemporal Operators | Returns a tuple that represents the i |
| **ST_LINEGETALLTIMESATPOINT** | Geospatial Spatiotemporal Operators | Returns a timestamp array of all tim |
| **ST_LINEGETPOINTATTIME** | Geospatial Spatiotemporal Operators | Returns a POINT within the bounds c specified TIMESTAMP value. |
| **ST_LINEGETTIMEATPOINT** | Geospatial Spatiotemporal Operators | Returns the interpolated time of the ARRAY. |
| **ST_LONGESTLINE** | Geospatial Spatiotemporal Operators | With the specified two LINESTRING-T represents the maximum distance b |
| **ST_SHORTESTLINE** | Geospatial Spatiotemporal Operators | When you specify two LINESTRING-T represents the minimum distance be |
| **HLL_SKETCH_CREATE** | HyperLogLog Functions | Creates an HLL sketch from the data representation of the sketch that yo |
| **HLL_SKETCH_GET_ESTIMATE** | HyperLogLog Functions | The scalar function converts a sketc estimate as a BIGINT. |
| **HLL_SKETCH_GET_ESTIMATE_BOUND** | HyperLogLog Functions | Takes a HLL_SKETCH column or an in confidence interval error proportion |
| **HLL_SKETCH_TO_STRING** | HyperLogLog Functions | The HLL_SKETCH_TO_STRING scalar the sketch. |
| **HLL_SKETCH_UNION (aggregate function)** | HyperLogLog Functions | Merges multiple sketches in a single function is an aggregate function an |
| **HLL_SKETCH_UNION (scalar function)** | HyperLogLog Functions | Merges two sketches into a new con function merges two sketch columns |
| **ABS** | Math Functions | Returns the absolute value of a spec |
| **ACOS** | Math Functions | Returns the inverse cosine of a spec |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **ACOSH** | Math Functions | Returns the hyperbolic arc-cosine of |
| **ASIN** | Math Functions | Returns the inverse sine of a specifi |
| **ASINH** | Math Functions | Returns the hyperbolic arc-sine of a |
| **ATAN** | Math Functions | Returns the inverse tangent of a spe |
| **ATAN2** | Math Functions | Returns the inverse tangent of two r |
| **ATANH** | Math Functions | Returns the hyperbolic arc-tangent |
| **BICDF** | Math Functions | The cumulative distribution function |
| **BIPDF** | Math Functions | The probability density function of tl |
| **BITAND** | Math Functions | Alias for the BITFUNC syntax `BITFUI` |
| **BITFUNC** | Math Functions | Performs a variety of bit operations. |
| **BITNOT** | Math Functions | Returns the bitwise negation of inte |
| **BITOR** | Math Functions | Alias for the BITFUNC syntax BITFUN |
| **BITXOR** | Math Functions | Alias for the BITFUNC syntax BITFUN |
| **BOOLAND** | Math Functions | Alias for the BOOLFUNC syntax BOO |
| **BOOLFUNC** | Math Functions | Performs a Boolean logical evaluatic `'XOR'`. |
| **BOOLNOT** | Math Functions | Returns the logical negation of the E |
| **BOOLOR** | Math Functions | Alias for the BOOLFUNC syntax BOO |
| **BOOLXOR** | Math Functions | Alias for the BOOLFUNC syntax BOO |
| **CBRT** | Math Functions | Returns the cube root of the numeri |
| **CDF** | Math Functions | The cumulative distribution function sample is less than or equal to the s |
| **CEIL** | Math Functions | Returns the nearest integer greater |
| **CEILING** | Math Functions | Alias for CEIL. |
| **COS** | Math Functions | Returns the cosine of x. |
| **COSH** | Math Functions | Returns the hyperbolic cosine of x. |
| **COT** | Math Functions | Returns the cotangent of x. |
| **DEGREES** | Math Functions | Returns the corresponding angle in |

| Function Name | Category Name | Function Description |
|---|---|---|
| **DIV** | Math Functions | Returns the result of x divided by y. |
| **ERF** | Math Functions | The error function is used for measu |
| **ERFC** | Math Functions | The complement of the error functic |
| **EXP** | Math Functions | Returns the exponential of x (e raise |
| **FLOOR** | Math Functions | Returns the nearest integer less tha |
| **GAMMA** | Math Functions | **Gamma function.** |
| **HEXBINX** | Math Functions | Returns the x-coordinate of the cent |
| **HEXBINY** | Math Functions | Returns the y-coordinate of the cent |
| **IERF** | Math Functions | The inverse of the ERF error functior |
| **IERFC** | Math Functions | The inverse of the complement of th |
| **LEAKYRELU** | Math Functions | Returns the leaky rectified linear uni |
| **LEFT_SHIFT** | Math Functions | Returns x shifted to the left by y bits |
| **LN** | Math Functions | Returns the natural logarithm of x. |
| **LOG** | Math Functions | Returns the base 10 logarithm of x. the function defaults to base 10. |
| **LOG_GAMMA** | Math Functions | The natural logarithm of the absolut |
| **LOG2** | Math Functions | Returns the base 2 logarithm of x. |
| **MOD** | Math Functions | Returns the remainder from x divide |
| **PI** | Math Functions | Returns the constant value of π. |
| **PMOD** | Math Functions | Returns the smallest non-negative e |
| **POWER** | Math Functions | Returns x raised to the power of y. |
| **PROBIT** | Math Functions | The inverse of the cumulative distrib |
| **RADIANS** | Math Functions | Returns the corresponding angle in r |
| **RAND** | Math Functions | Takes no argument and returns a ran |
| **RELU** | Math Functions | Returns the rectified linear unit func |
| **RIGHT_SHIFT** | Math Functions | Returns x shifted to the right by y bi |
| **ROUND** | Math Functions | Returns x rounded to the nearest int |
| **SIGN** | Math Functions | Returns the positive (+1), zero (0), o |

| Function Name | Category Name | Function Description |
|---|---|---|
| **SIN** | Math Functions | Returns the sine of x. |
| **SINH** | Math Functions | Returns the hyperbolic sine of x. |
| **SQRT** | Math Functions | Returns the square root of x. |
| **SQUARE** | Math Functions | Returns the square of x. |
| **TAN** | Math Functions | Returns the tangent of x. |
| **TANH** | Math Functions | Returns the hyperbolic tangent of x. |
| **TO_BASE** | Math Functions | Converts an integer value to its strir |
| **TRUNC** | Math Functions | Returns x truncated to y decimal pla |
| **TRUNCATE** | Math Functions | Alias for TRUNC. |
| **ABS** | Matrix Functions | Returns magnitude of one-dimensio |
| **CROSS_ENTROPY_LOSS** | Matrix Functions | Returns the cross entropy loss of tw |
| **DET** | Matrix Functions | Returns the determinant of the matı |
| **DOT** | Matrix Functions | Returns dot product of two one-dime |
| **EIGEN** | Matrix Functions | Returns eigenvalues and eigenvalue |
| **FROBENIUS** | Matrix Functions | Returns the Frobenius norm of a ma |
| **HINGE_LOSS** | Matrix Functions | Returns the hinge loss of two one-di |
| **IDENTITY_MATRIX** | Matrix Functions | Returns an identity matrix of the spe |
| **INVERSE** | Matrix Functions | Returns inverse of a square, invertib |
| **LOG_LOSS** | Matrix Functions | Returns the log loss of two one-dime |
| **LOGITS_LOSS** | Matrix Functions | Returns the logits loss of two one-di |
| **LUPQ_DECOMP** | Matrix Functions | Returns LUPQ decomposition of a sq |
| **MATRIX_DIM** | Matrix Functions | Returns the dimensions of the speci |
| **MAKE_MATRIX_IXJ** | Matrix Functions | Creates an `ixj` matrix with elemer |
| **MATRIX_FROM_TEXT** | Matrix Functions | Creates a matrix from the specified |
| **MATRIX_TRACE** | Matrix Functions | Returns trace of a square matrix as |
| **NULL_MATRIX** | Matrix Functions | Returns a NULL matrix of the specifi |
| **QR_DECOMP** | Matrix Functions | Returns QR decomposition of a matı |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **SOFTMAX** | Matrix Functions | Returns the softmax of a one-dimen |
| **SVD_DECOMP** | Matrix Functions | Returns SVD decomposition of a ma |
| **TRANSPOSE** | Matrix Functions | Returns transpose of the matrix. |
| **VECTOR_ARGMAX** | Matrix Functions | Returns the argmax of a one-dimens |
| **VECTOR_ARGMIN** | Matrix Functions | Returns the argmin of a one-dimens |
| **VECTOR_MAX** | Matrix Functions | Returns the maximum of elements i |
| **VECTOR_MIN** | Matrix Functions | Returns the minimum of elements ir |
| **VECTOR_SUM** | Matrix Functions | Returns the sum of elements in a or |
| **ZERO_MATRIX** | Matrix Functions | Returns a zero matrix of the given (r |
| **IP** | Network Type Functions | Casts an IP data type from an IPV4 c |
| **IPV4** | Network Type Functions | Casts an IPV4 address from an IPV6 |
| **IS_IPV4** | Network Type Functions | Tests whether the database can con |
| **SUBNET** | Network Type Functions | Computes the prefix from an `IP` or |
| **CANCEL** | Query Management | Cancels a running query based on it |
| **KILL** | Query Management | Kills a running query identified by its |
| **BIGINT** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **BINARY** | Scalar Data Conversion Functions | Parses a hexadecimal string (such a |
| **BOOLEAN** | Scalar Data Conversion Functions | Parses a string to create a Boolean v |
| **BYTE** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **CHAR** | Scalar Data Conversion | Creates a string version of the nume |

| Function Name | Category Name | Function Description |
|---|---|---|
| | Functions | |
| **DATE** | Scalar Data Conversion Functions | Parses a string in the form 'YYYY-MM |
| **DAYS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **DECIMAL** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **DOUBLE** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **FLOAT** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **HASH** | Scalar Data Conversion Functions | Creates a fixed length binary value, string does not have enough bytes, |
| **HOURS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **INTEGER** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **MAP_DELETE** | Scalar Data Conversion Functions | Removes the entry for the specified |
| **MAP_GET** | Scalar Data Conversion Functions | Returns the value for the specified k |
| **MAP_PUT** | Scalar Data Conversion Functions | Inserts a key-value pair into a map c |
| **MICROSECONDS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **MILLISECONDS** | Scalar Data Conversion Functions | Converts an integral value to an inte |

| Function Name | Category Name | Function Description |
|---|---|---|
| **MINUTES** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **MONTHS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **NANOSECONDS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **SECONDS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **SMALLINT** | Scalar Data Conversion Functions | Casts the argument to a value of typ |
| **TIME** | Scalar Data Conversion Functions | Parses the string to create a time va |
| **TIMESTAMP** | Scalar Data Conversion Functions | Parses a string and makes a timesta |
| **UUID** | Scalar Data Conversion Functions | Parses the string and makes a UUID |
| **WEEKS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **YEARS** | Scalar Data Conversion Functions | Converts an integral value to an inte |
| **ARRAY_CAP** | Special Data Pipeline Transformation Functions | Restrict the length of an array to a r |
| **ARRAY_COMPACT** | Special Data Pipeline Transformation Functions | Removes NULL values from the arra |
| **ARRAY_CONTAINS** | Special Data Pipeline | Returns `true` if the array contains |

| Function Name | Category Name | Function Description |
|---|---|---|
| | Transformation Functions | |
| **ARRAY_SORT** | Special Data Pipeline Transformation Functions | Sort and return the input array base |
| **CASE WHEN** | Special Data Pipeline Transformation Functions | Returns the `result` value based or |
| **ELEMENT_AT** | Special Data Pipeline Transformation Functions | Returns the element value of the arı |
| **EXPLODE_OUTER** | Special Data Pipeline Transformation Functions | Expands a one-dimensional or multi system. |
| **FILTER** | Special Data Pipeline Transformation Functions | Filters elements in an array based o |
| **FLATTEN** | Special Data Pipeline Transformation Functions | Transforms an `N`-dimensional array |
| **IF** | Special Data Pipeline Transformation Functions | Returns `T` if the expression `X` ev |
| **LOOKUP** | Special Data Pipeline Transformation Functions | Look up and load data in an externa |
| **MAP_KEYS** | Special Data Pipeline Transformation Functions | Returns the keys in the specified JSC |
| **MAP_VALUES** | Special Data Pipeline Transformation Functions | Returns the values in the specified J |

| Function Name | Category Name | Function Description |
|---|---|---|
| **METADATA** | Special Data Pipeline Transformation Functions | Extracts the metadata value for the |
| **PARSE_DELIMITED_ARRAY** | Special Data Pipeline Transformation Functions | Converts a string of text data repres |
| **REDUCE** | Special Data Pipeline Transformation Functions | Applies a merge function to a startir value. Optionally, specify a finish fu |
| **TO_ARRAY_LENGTH** | Special Data Pipeline Transformation Functions | Create the specified number of copi |
| **TRANSFORM** | Special Data Pipeline Transformation Functions | Transforms an array based on the lo |
| **WIDTH_BUCKET** | Special Data Pipeline Transformation Functions | Creates `N` equal-width buckets in t |
| **ZIP_WITH** | Special Data Pipeline Transformation Functions | Merges two or more input arrays, el |
| **RECORD_UUID** | Other Transformation Functions | Returns string that represents a uni topic. |
| **COMMIT** | Other Functions and Expressions | Returns the most recent commit has |
| **RAND_UUID** | Other Functions and Expressions | Generates a random UUID value (ve |
| **TYPE_STRIP** | Other Functions and Expressions | Returns the SQL type of the specifie |
| **UUID_GENERATE** | Other Functions and Expressions | Generates a random UUID value (ve |
| **CURRENT_DATABASE** | System Functions | Alias for DATABASE. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function Name | Category Name | Function Description |
|---|---|---|
| **CURRENT_GROUPS** | System Functions | Returns the fully-qualified names of |
| **CURRENT_NODE** | System Functions | Returns the name of the SQL Node v column in the `sys.nodes` system ca |
| **CURRENT_NODE_ID** | System Functions | Returns the identifier of the SQL Noc |
| **CURRENT_SCHEMA** | System Functions | Returns the name of the current sch |
| **CURRENT_SESSION_ID** | System Functions | Returns the Universally Unique IDen |
| **CURRENT_SYSTEM** | System Functions | Returns the name of the system. |
| **CURRENT_USER** | System Functions | Returns the user for the current con |
| **DATABASE** | System Functions | Returns the name of the database t |
| **SHOW** | System Functions | The SHOW function enables you to e |
| **VERSION** | System Functions | Returns the version of the database |
| **CONVERT_LOCAL_TIMESTAMP_TO_UTC** | Time Zone Functions | The function converts a timestamp i |
| **CONVERT_UTC_TIMESTAMP_TO_LOCAL** | Time Zone Functions | The function converts a timestamp f |
| **CAST_TO_TUPLE** | Tuple Functions | Converts a tuple into another tuple |
| **CHAR** | Tuple Functions | Converts a tuple to its string represe |
| **STRING_TO_TUPLE** | Tuple Functions | Converts the string representation c |
| **TUPLE()** | Tuple Functions | Construct a tuple of specified eleme |
| **TUPLE<<>>** | Tuple Functions | Construct a tuple of specified eleme |
| **CUME_DIST** | Window Aggregate Functions | Returns a number 0 < n 1 and can b value in the group. |
| **DELTA** | Window Aggregate Functions | Computes the finite difference betw backwards difference, which means of expression for that row and the p |

# Aggregate Functions

Reference for Ocient SQL aggregate functions, including SUM, AVG, COUNT, MIN, MAX, and approximate aggregates for computing values across rows in queries.

The OcientAIQ™ Unified Data Platform has aggregated and sorted aggregate functions. Aggregate and sorted aggregate functions compute a single result from a group of rows. You can use the `DISTINCT` keyword with any aggregation function, such as `COUNT(DISTINCT col)`. Whereas sorted aggregate functions use the standard ORDER BY syntax to dictate the ordering of the aggregation. To sort the elements of an array, use the **ARRAY_SORT** function during data load.

## Aggregate Functions

Supported input types vary by function. In general, numeric types include `TINYINT`, `SMALLINT`, `INT`, `BIGINT`, `FLOAT`, `DOUBLE`, and `DECIMAL`.

Various examples on this page use these tables.

SQL

```
CREATE TABLE sample_data (val INT, label VARCHAR(10));
INSERT INTO sample_data (val, label) VALUES
    (2, 'alpha'), (4, 'beta'), (4, 'alpha'), (5, NULL),
    (7, 'gamma'), (8, 'alpha'), (12, 'beta'), (15, 'gamma');
```

SQL

```
CREATE TABLE predictions (actual INT, predicted INT);
INSERT INTO predictions (actual, predicted) VALUES
    (10, 12), (20, 18), (30, 33),
    (40, 37), (50, 52), (60, 58);
```

For simple functions, examples use the `sys.dummy` virtual table. For details, see **Generate Tables Using sys.dummy**.

# ACCURACY_SCORE

Returns the fraction of predictions that match the actual class labels. This function calculates the ratio of correctly predicted rows to the total number of rows.

```
SQL

ACCURACY_SCORE(y, y_hat)
```

| Argument | Data Type | Description |
|---|---|---|
| `y` | All types supported | The actual class label. |
| `y_hat` | All types supported | The predicted class label. |

The return type is `DOUBLE`. The result represents the proportion of correct predictions, ranging from 0 to 1.

### Examples

#### Calculate the Accuracy Score for Matched Values

This query returns the accuracy score when all predictions match the actual values.

```
SQL

SELECT ACCURACY_SCORE(c1, c1) FROM sys.dummy10;
```

Output: `1`

#### Calculate the Accuracy Score with Comparison Against Squared Values

This query returns the accuracy score when comparing actual values against their squared values.

```
SQL

SELECT ACCURACY_SCORE(c1, c1 * c1) FROM sys.dummy10;
```

Output: `0.1`

## ANY_VALUE

Returns an arbitrary non-`NULL` value from the input column. The function returns `NULL` only if all rows in the column are `NULL`.

The `ANY_VALUE` function does not support window aggregation.

### Syntax

```
SQL

ANY_VALUE(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any type | The column from which to return an arbitrary non-`NULL` value. |

### Example

```
SQL

SELECT
    ANY_VALUE(label) AS sample_label
FROM sample_data;
```

Output: `alpha`

> The returned value is non-deterministic. The database can return any non-`NULL` value from the column.

## APPROX_COUNT_DISTINCT

Returns an approximate count of distinct values in the column using the HyperLogLog algorithm, with a 95% confidence interval that the result is within 4.5% of the exact count.

### Syntax

```sql
APPROX_COUNT_DISTINCT(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any non-interval type | The column for the approximation of the distinct count. |

### Example

```sql
SELECT
    APPROX_COUNT_DISTINCT(val) AS approx_distinct
FROM sample_data;
```

Output: `7`

The `sample_data` table has eight rows, but there are only seven distinct values in the `val` column (the value `4` appears twice).

## APPROX_SUM

Computes a sum using a faster, non-deterministic ordering for floating-point columns. This summation can lead to minor differences in the result on the order of the machine epsilon. For integral column types, the function uses the standard `SUM` algorithm.

### Syntax

```sql
APPROX_SUM(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | `FLOAT`, `DOUBLE`, or any integral type | The column to sum. |

For integral inputs, the `APPROX_SUM` function uses the standard `SUM` algorithm and returns the same result. The performance benefit applies to large floating-point data sets.

### Example

```sql
SELECT
    APPROX_SUM(c1) AS approx_total
FROM sys.dummy5;
```

Output: `15`

## AVG

Computes the arithmetic mean over the set of values.

### Syntax

```sql
AVG(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any numeric type or `MATRIX` | The column to average.<br><br>Integral and `FLOAT` inputs return `DOUBLE`.<br><br>`DOUBLE`, `DECIMAL`, and `MATRIX` inputs preserve their type. |

### Example

```sql
SELECT
    AVG(c1) AS avg_val
FROM sys.dummy5;
```

Output: `3.0`

## COEFFICIENT_OF_DETERMINATION

Computes the coefficient of determination ($R^2$) between actual and predicted values. Primarily used to evaluate the performance of machine learning regression models, $R^2$ measures the proportion of variance in the actual values that the predicted values explain. A value of `1.0` indicates a perfect fit, while `0.0` indicates that the predictions explain none of the variance.

This function returns `NULL` when the total sum of squares is zero (i.e., all actual values are identical).

### Syntax

```
SQL

COEFFICIENT_OF_DETERMINATION(actual, predicted)
```

| Argument | Data Type | Description |
|---|---|---|
| `actual` | Any numeric type | The column of observed values. |
| `predicted` | Any numeric type | The column of predicted values. |

### Example

```
SQL

SELECT
    COEFFICIENT_OF_DETERMINATION(actual, predicted) AS r_squared
FROM predictions;
```

Output: `0.980571428571429`

## CONFUSION_MATRIX

Returns a structured representation of the counts for every combination of actual and predicted class labels relative to a specified positive class. This function aggregates

predictions into a 2x2 matrix in the format `[[TP, FP], [FN, TN]]` for binary classification analysis.

```
SQL

CONFUSION_MATRIX(y, y_hat, positive_class)
```

| Argument | Data Type | Description |
|---|---|---|
| `y` | All types supported | The actual class label. |
| `y_hat` | All types supported | The predicted class label. |
| `positive_class` | All types supported | The class label to treat as the positive class. Must match the type of `y` and `y_hat`. |

The return type is `TUPLE`. Each entry in the result contains the count of rows for a specific combination of actual and predicted class values, organized as true positives, false positives, false negatives, and true negatives.

### Examples

#### Calculate the Confusion Matrix with Matched Values

This query returns the confusion matrix when all predictions match the actual values.

```
SQL

SELECT CONFUSION_MATRIX(
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    1
) FROM sys.dummy10;
```

Output: `[[5, 0], [0, 5]]`

#### Calculate the Confusion Matrix with Mismatched Classifiers

This query returns the confusion matrix for two mismatched binary classifiers, where actual positives are rows with `c1 > 5` and predicted positives are rows with `c1 < 3`.

```sql
SELECT CONFUSION_MATRIX(
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    CASE WHEN c1 < 3 THEN 1 ELSE 0 END,
    1
) FROM sys.dummy10;
```

Output: `[[0, 2], [5, 3]]`

## CORR

Alias for **CORRELATIONP**.

## CORRELATION

Alias for **CORRELATIONP**.

## CORRELATIONP

Computes the population Pearson correlation coefficient between two columns. Returns `DOUBLE`, or `DECIMAL` if both inputs are `DECIMAL`-compatible.

Alias for `CORRELATION` and `CORR`.

### Syntax

```sql
CORRELATIONP(col1, col2)
```

| Argument | Data Type | Description |
|---|---|---|
| `col1` | Any numeric type | The first column. |
| `col2` | Any numeric type | The second column. |

### Example

```sql
SELECT
    CORRELATIONP(actual, predicted) AS corr_val
FROM predictions;
```

Output: `0.9904654955172436`

## COUNT

Returns the number of rows in the set where values in `col` are not `NULL`. When you use the `COUNT(*)` SQL statement, the function returns the total number of rows. The return type is `BIGINT`.

### Syntax

```sql
COUNT(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any non-interval type | The column for counting non-`NULL` values.<br>Use `*` to count all rows instead. |

### Examples

### Count All Rows

```sql
SELECT COUNT(*) AS total_rows FROM sample_data;
```

Output: `8`

### Count Non-NULL Values

The `label` column has one `NULL` row.

```
SQL

SELECT COUNT(label) AS rows_with_label FROM sample_data;
```

Output: `7`

## COVAR_POP

Alias for **COVARIANCEP**.

## COVAR_SAMP

Alias for **COVARIANCE**.

## COVARIANCE

Computes the sample covariance between two columns. Returns `DOUBLE` by default, or `DECIMAL` if both inputs are `DECIMAL`-compatible. `MATRIX` inputs preserve their type.

Alias for `COVAR_SAMP`.

### Syntax

```
SQL

COVARIANCE(col1, col2)
```

| Argument | Data Type | Description |
|---|---|---|
| `col1` | Any numeric type or `MATRIX` (square) | The first column. |
| `col2` | Any numeric type or `MATRIX` (square) | The second column. |

> Matrix arguments must have matching dimensions.

### Example

```sql
SELECT
    COVARIANCE(actual, predicted) AS cov_samp
FROM predictions;
```

Output: `336.0`

## COVARIANCEP

Computes the population covariance between two columns. Returns `DOUBLE` by default, or `DECIMAL` if both inputs are compatible with `DECIMAL`.

`MATRIX` inputs preserve their type.

Alias for `COVAR_POP`.

### Syntax

```sql
COVARIANCEP(col1, col2)
```

| Argument | Data Type | Description |
|---|---|---|
| `col1` | Any numeric type or `MATRIX` (square) | The first column. |
| `col2` | Any numeric type or `MATRIX` (square) | The second column. |

Matrix arguments must have matching dimensions.

### Example

```sql
SELECT
    COVARIANCEP(actual, predicted) AS cov_pop
FROM predictions;
```

Output: `280.0`

## F1_SCORE

Returns the harmonic mean of precision and recall for a specified positive class. This function calculates `2 * (Precision * Recall) / (Precision + Recall)` and provides a single score that balances both precision and recall. The function returns `NULL` when both precision and recall are 0.

SQL

```
F1_SCORE(y, y_hat, positive_class)
```

| Argument | Data Type | Description |
|---|---|---|
| `y` | All types supported | The actual class label. |
| `y_hat` | All types supported | The predicted class label. |
| `positive_class` | All types supported | The class label to treat as the positive class. Must match the type of `y` and `y_hat`. |

The return type is `DOUBLE`. The result ranges from 0 to 1, where 1 represents perfect precision and recall.

### Examples

#### Calculate the F1 Score with Matching Values

This query returns the F1 score when all predictions match the actual values.

SQL

```
SELECT F1_SCORE(
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    1
) FROM sys.dummy10;
```

© 2026 Ocient, Inc

Output: `1`

### Calculate the F1 Score for Mismatched Classifiers

This query returns `NULL` because both precision and recall are 0 for the mismatched classifiers.

```sql
SELECT F1_SCORE(
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    CASE WHEN c1 < 3 THEN 1 ELSE 0 END,
    1
) FROM sys.dummy10;
```

Output: `NULL`

## KURTOSIS

Computes the sample excess kurtosis over the set of values. Kurtosis measures the difference between the tails of a distribution and the tails of a normal distribution. Returns `DOUBLE`, or `DECIMAL` if the input is `DECIMAL`.

### Syntax

```sql
KURTOSIS(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any numeric type | The column for computing the sample kurtosis. |

### Example

```sql
SELECT
    KURTOSIS(val) AS kurt_val
FROM sample_data;
```

Output: `4.763725276787391`

## KURTOSISP

Computes the population kurtosis over the set of values. Returns `DOUBLE`, or `DECIMAL` if the input is `DECIMAL`.

### Syntax

```sql
KURTOSISP(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any numeric type | The column for computing population kurtosis. |

### Example

```sql
SELECT
    KURTOSISP(val) AS kurtp_val
FROM sample_data;
```

Output: `2.268440607993995`

## MAX

Returns the maximum value in the specified column. The return type matches the input.

### Syntax

```sql
MAX(col)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `col` | Any non-interval type | The column for returning the maximum value. |

### Example

```sql
SELECT
    MAX(c1) AS max_val
FROM sys.dummy5;
```

Output: `5`

## MEAN_ABSOLUTE_ERROR

Returns the mean absolute error (MAE) between actual and predicted values. This function calculates the average of the absolute differences between each pair of actual and predicted values, treating all errors equally regardless of direction.

```sql
MEAN_ABSOLUTE_ERROR(y, y_hat)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `y` | NUMERIC | The actual value. |
| `y_hat` | NUMERIC | The predicted value. |

The return type is `DOUBLE`. The result is always zero or positive. A value of 0 indicates perfect predictions.

Examples

### Calculate the MAE for Matched Values

This query returns the mean absolute error when all predictions match the actual values.

SQL

```
SELECT MEAN_ABSOLUTE_ERROR(c1, c1) FROM sys.dummy10;
```

Output: `0`

### Calculate the MAE with Comparison Against Squared Values

This query returns the mean absolute error when comparing actual values against their squared values.

SQL

```
SELECT MEAN_ABSOLUTE_ERROR(c1, c1 * c1) FROM sys.dummy10;
```

Output: `33.0`

## MEAN_ABSOLUTE_PERCENTAGE_ERROR

Returns the mean absolute percentage error (MAPE) between actual and predicted values. This function calculates the average of the absolute percentage differences using the formula `Average( AbsoluteValue( (y - y_hat) / y ) ) * 100`, which expresses the error relative to the actual values.

SQL

```
MEAN_ABSOLUTE_PERCENTAGE_ERROR(y, y_hat)
```

| Argument | Data Type | Description |
|---|---|---|
| `y` | NUMERIC | The actual value. Must not be 0, because this value is the denominator in the percentage calculation. |
| `y_hat` | NUMERIC | The predicted value. |

The return type is `DOUBLE`. The result is a percentage value where 0 indicates perfect predictions.

Examples

### Calculate the MAPE for Matched Values

This query returns the mean absolute percentage error when all predictions match the actual values.

```SQL
SELECT MEAN_ABSOLUTE_PERCENTAGE_ERROR(c1, c1) FROM sys.dummy10;
```

Output: `0`

### Calculate the MAPE with Comparison Against Squared Values

This query returns the mean absolute percentage error when comparing actual values against their squared values.

```SQL
SELECT MEAN_ABSOLUTE_PERCENTAGE_ERROR(c1, c1 * c1)
    FROM sys.dummy10;
```

Output: `450.0`

## MIN

Returns the minimum value in the specified column. The return type matches the input.

### Syntax

```SQL
MIN(col)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `col` | Any non-interval type | The column for returning the minimum value. |

### Example

```SQL
SELECT
    MIN(c1) AS min_val
FROM sys.dummy5;
```

Output: `1`

## PRECISION_SCORE

Returns the precision score for a specified positive class. This function calculates the ratio of true positives to the total number of predicted positives using the formula `True Positives / (True Positives + False Positives)`. Of all the predictions for the specified class, this score measures how many are correct.

```SQL
PRECISION_SCORE(y, y_hat, positive_class)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `y` | All types supported | The actual class label. |
| `y_hat` | All types supported | The predicted class label. |
| `positive_class` | All types supported | The class label to treat as the positive class. Must match the type of `y` and `y_hat`. |

The return type is `DOUBLE`. The result ranges from 0 to 1, where 1 indicates that every prediction for the positive class is correct.

### Examples

### Calculate the Precision Score for Matched Values

This query returns the precision score when all predictions match the actual values.

SQL

```
SELECT PRECISION_SCORE(
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    1
) FROM sys.dummy10;
```

Output: `1`

### Calculate the Precision Score for Mismatched Classifiers

This query returns the precision score for two mismatched binary classifiers, where none of the predicted positives are actual positives.

SQL

```
SELECT PRECISION_SCORE(
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    CASE WHEN c1 < 3 THEN 1 ELSE 0 END,
    1
) FROM sys.dummy10;
```

Output: `0.0`

## PRODUCT

Computes the product of all values in the column.

### Syntax

SQL

```
PRODUCT(col)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `col` | `FLOAT`, `DOUBLE`, `DECIMAL`, any integral type, or `MATRIX` (square) | The column to multiply. Integral inputs return `BIGINT`. |

Matrix arguments must have matching dimensions.

### Example

SQL

```
SELECT
    PRODUCT(c1) AS factorial_5
FROM sys.dummy5;
```

Output: `120`

## RECALL_SCORE

Returns the recall score for a specified positive class. This function calculates the ratio of true positives to the total number of actual positives using the formula `True Positives / (True Positives + False Negatives)`. Of all the actual instances of the specified class, this score measures how many the model correctly identifies.

SQL

```
RECALL_SCORE(y, y_hat, positive_class)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `y` | All types supported | The actual class label. |
| `y_hat` | All types supported | The predicted class label. |
| `positive_class` | All types supported | The class label to treat as the positive class. Must match the type of `y` and `y_hat`. |

The return type is `DOUBLE`. The result ranges from 0 to 1, where 1 indicates that every actual instance of the positive class is correctly identified.

### Examples

#### Calculate the Recall Score for Matched Values

This query returns the recall score when all predictions match the actual values.

SQL

```
SELECT RECALL_SCORE(
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    1
) FROM sys.dummy10;
```

Output: `1`

#### Calculate the Recall Score for Mismatched Classifiers

This query returns the recall score for two mismatched binary classifiers, where none of the actual positives are correctly predicted.

SQL

```
SELECT RECALL_SCORE(
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    CASE WHEN c1 < 3 THEN 1 ELSE 0 END,
    1
) FROM sys.dummy10;
```

Output: `0.0`

## ROC_AUC_SCORE

Returns the area under the receiver operating characteristic (ROC) curve (AUC). This function measures the ability of a binary classification model to distinguish between classes. A score of 1.0 represents a perfect classifier, while a score of 0.5 represents performance no better than random guessing.

SQL

```
ROC_AUC_SCORE(y_true, y_score, positive_class)
```

| Argument | Data Type | Description |
|---|---|---|
| `y_true` | BOOLEAN or INTEGER | The true binary class label, where the values represent two classes (for example, 0 or 1). |
| `y_score` | NUMERIC | The predicted probability or confidence score for the positive class. A score of 1.0 is a perfect classifier, while 0.5 is no better than random guessing. |
| `positive_class` | | The class label to treat as the positive class. Must match the type of `y_true`. |

The return type is `DOUBLE`. The result ranges from 0 to 1.

### Example

This query returns the AUC score for a classifier in which higher probability scores correspond to actual positives, indicating perfect class separation.

SQL

```
SELECT ROC_AUC_SCORE(
    CASE WHEN c1 > 5 THEN 1 ELSE 0 END,
    DOUBLE(c1) / 10,
    1
) FROM sys.dummy10;
```

Output: `1.0`

## ROOT_MEAN_SQUARED_ERROR

Returns the root mean squared error (RMSE) between actual values and predicted values. This function calculates the square root of the average of the squared differences between the actual and predicted values, providing an error metric in the same units as the target variable. Use this function to evaluate machine learning model quality by comparing model predictions against known actual values on a holdout or test data set.

```sql
ROOT_MEAN_SQUARED_ERROR(y, y_hat)
```

| Argument | Data Type | Description |
|---|---|---|
| `y` | Numeric types | The actual value. |
| `y_hat` | Numeric types | The predicted value. |

The return type is `DOUBLE`.

### Examples

#### Calculate RMSE for Predictions

This query returns the RMSE between actual and predicted values.

```sql
SELECT ROOT_MEAN_SQUARED_ERROR(
    actual,
    predicted
) FROM predictions;
```

Output

```
2.160246899469287
```

#### Calculate RMSE with Perfect Predictions

This query returns 0 when predictions exactly match actual values.

```sql
SELECT ROOT_MEAN_SQUARED_ERROR(
    actual,
    actual
) FROM predictions;
```

© 2026 Ocient, Inc

Output

```
0.0
```

## SKEW

Computes the sample skewness over the set of values. Skewness measures the asymmetry of a distribution. Returns `DOUBLE`, or `DECIMAL` if the input is `DECIMAL`.

### Syntax

SQL

```
SKEW(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any numeric type | The column for computing the sample skewness. |

### Example

SQL

```
SELECT
    SKEW(val) AS skew_val
FROM sample_data;
```

Output: `0.8804164883619399`

## SKEWP

Computes the population skewness over the set of values. Returns `DOUBLE`, or `DECIMAL` if the input is `DECIMAL`.

### Syntax

```sql
SKEWP(col)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `col` | Any numeric type | The column for computing the population skewness. |

### Example

```sql
SELECT
    SKEWP(val) AS skewp_val
FROM sample_data;
```

Output: `0.7059036122393627`

## STDEV

Computes the sample standard deviation over the set of values. Returns `DOUBLE`, or `DECIMAL` if the input is `DECIMAL`.

Alias for `STDDEV` and `STDDEV_SAMP`.

### Syntax

```sql
STDEV(col)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `col` | Any numeric type | The column for computing the sample standard deviation. |

### Example

```sql
SELECT
    STDEV(val) AS stdev_val
FROM sample_data;
```

Output: `4.421942042651783`

## STDDEV

Alias for **STDEV**.

## STDDEV_POP

Alias for **STDEVP**.

## STDDEV_SAMP

Alias for **STDEV**.

## STDEVP

Computes the population standard deviation over the set of values. Returns `DOUBLE`, or `DECIMAL` if the input is `DECIMAL`.

Alias for `STDDEV_POP`.

### Syntax

```sql
STDEVP(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any numeric type | The column for computing the population standard deviation. |

### Example

```sql
SELECT
    STDEVP(val) AS stdevp_val
FROM sample_data;
```

Output: `4.136348026943574`

## SUM

Computes the sum of all values in the column.

### Syntax

```sql
SUM(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any numeric type or `MATRIX` | The column to sum.<br><br>Integral inputs return `BIGINT`.<br>d<br>`FLOAT` inputs return `FLOAT`.<br><br>`DOUBLE`, `DECIMAL`, and `MATRIX` inputs preserve their type. |

### Example

```sql
SELECT
    SUM(c1) AS total
FROM sys.dummy5;
```

Output: `15`

## VAR_POP

Alias for **VARIANCEP**.

## VAR_SAMP

Alias for **VARIANCE**.

## VARIANCE

Computes the sample variance over the set of values. Returns `DOUBLE`, or `DECIMAL` if the input is `DECIMAL`.

`MATRIX` inputs preserve their type and must be square.

Alias for `VAR_SAMP`.

### Syntax

```sql
VARIANCE(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any numeric type or `MATRIX` (square) | The column for computing the sample variance. |

> Matrix arguments must have matching dimensions.

### Example

```sql
SELECT
    VARIANCE(val) AS var_val
FROM sample_data;
```

Output: `19.553571428571427`

## VARIANCEP

Computes the population variance over the set of values. Returns `DOUBLE`, or `DECIMAL` if the input is `DECIMAL`.

`MATRIX` inputs preserve their type and must be square.

Alias for `VAR_POP`.

### Syntax

```
SQL

VARIANCEP(col)
```

| Argument | Data Type | Description |
|---|---|---|
| `col` | Any numeric type or `MATRIX` (square) | The column for computing population variance. |

### Example

```
SQL

SELECT
    VARIANCEP(val) AS varp_val
FROM sample_data;
```

Output: `17.109375`

## Sorted Aggregate Functions

The general syntax for sorted aggregate functions adds the DISTINCT and ORDER BY keywords in the function invocation.

```
SQL

AGGREGATE([DISTINCT] arg1, arg2, ... [ORDER BY ...])
```

### ARRAY_AGG

Returns an array containing every row from the expression.

### Syntax

```
SQL

ARRAY_AGG(expr)
```

| Argument | Data Type | Description |
|---|---|---|
| `expr` | Any numeric type | Expression for aggregation into an array. |

### Example

Aggregate ten rows into an array in descending order.

```
SQL

SELECT
    ARRAY_AGG(c1 ORDER BY c1 DESC)
FROM sys.dummy10;
```

Output: `[10,9,8,7,6,5,4,3,2,1]`

## ARRAY_CONCAT_AGG

Returns an array that concatenates arrays across rows. The input argument is a SQL expression. The element type must be consistent across rows. The function ignores NULL inputs and returns NULL only when all inputs are NULL.

The `DISTINCT` keyword removes duplicate arrays. To remove duplicate elements from an array, use the `ARRAY_DISTINCT` function during load.

The `ORDER BY` syntax controls the order of concatenation across rows. To sort elements in the array, use the `ARRAY_SORT` function during load.

### Syntax

SQL

```
ARRAY_CONCAT_AGG(expr)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `expr` | SQL expression | Expression for concatenation across rows. |

### Example

Create the `data_type_example` table with a column that stores arrays of integers.

SQL

```
CREATE TABLE
    data_type_example (col_int_array INT[] NOT NULL DEFAULT 'INT[0,1,2,3]');
```

Insert one array with values `1`, `2`, and `3` into the table.

SQL

```
INSERT INTO data_type_example SELECT ARRAY[1,2,3];
```

Insert the second array with values `4`, `5`, and `6` into the table.

SQL

```
INSERT INTO data_type_example SELECT ARRAY[4,5,6];
```

Concatenate the two arrays into one array in ascending order.

SQL

```
SELECT ARRAY_CONCAT_AGG(col_int_array ORDER BY col_int_array ASC)
FROM data_type_example;
```

Output: `[1,2,3,4,5,6]`

## STRING_AGG

Returns a string concatenated from every row of the expression.

### Syntax

```SQL
ARRAY_CONCAT_AGG(expr, delimiter)
```

| Argument | Data Type | Description |
|---|---|---|
| `expr` | SQL expression | Expression for concatenation across rows. |
| `delimiter` | | Optional. |

### Examples

#### Concatenate Rows as a String

Concatenate ten rows into a string in descending order. Cast integers into strings using the `CHAR` casting function.

```SQL
SELECT
    STRING_AGG(char(c1) ORDER BY c1 DESC)
FROM sys.dummy10;
```

Output: `"10987654321"`

#### Concatenate Rows as a String with a Delimiter

Concatenate ten rows into a string in ascending order. Cast integers into strings using the `CHAR` casting function. Use the `|` delimiter.

SQL

```
SELECT
    STRING_AGG(char(c1), '|' ORDER BY c1 ASC)
FROM sys.dummy10;
```

Output: `"1|2|3|4|5|6|7|8|9|10"`

# Array Functions and Operators

Reference for Ocient SQL array functions and operators, with examples for constructing, accessing, slicing, concatenating, and aggregating array values.

The Ocient® System enables you to work with data as arrays. The system contains functions that work with arrays and operators that enable you to parse data within arrays.

## ARRAY_CAT_DISTINCT

Concatenates two or more arrays in the order of the input arguments. After concatenation, the function removes duplicates from the result array while preserving the first occurrence order. The function skips any NULL input arguments. If all input arrays are NULL, the function returns a NULL. If at least one NULL element is present in the array, the function returns a NULL in the result array with the position of the first NULL the function finds in the order of the input arguments.

### Syntax

SQL

```
ARRAY_CAT_DISTINCT(input_array1, input_array2 [, ...])
```

| Argument | Data Type | Description |
|---|---|---|
| `input_array1, input_array2 [, ...]` | ARRAY | Two or more arrays for concatenation and deduplication. The elements within all input arrays must have the same data type. |

### Examples

#### Concatenate Two Arrays and Remove Duplicates

Concatenate two arrays and remove duplicate elements within the arrays.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

```sql
SELECT ARRAY_CAT_DISTINCT(ARRAY[1,2,2,3,1], ARRAY[2,3,4,4,5]);
```

Output: `[1,2,3,4,5]`

### Concatenate Two Arrays with NULLs and Remove Duplicates

Deduplicate the contents of the array. In this case, the array contains NULLs.

```sql
SELECT ARRAY_CAT_DISTINCT(ARRAY[1,2,2,NULL,1], ARRAY[2,4,4,NULL]);
```

Output: `[1,2,NULL,4]`

## ARRAY_DISTINCT

Removes duplicates from an array while preserving the first occurrence order. If at least one NULL is present in the array, the function returns a NULL with the position of the first NULL of the input array in the output array.

### Syntax

```sql
ARRAY_DISTINCT(input_array)
```

| Argument | Data Type | Description |
|---|---|---|
| `input_array` | ARRAY | The array for deduplication. |

### Examples

### Remove Duplicates from an Array

Deduplicate the contents of the array.

```sql
SELECT ARRAY_DISTINCT(ARRAY[1,2,2,3,1]);
```

Output: `[1,2,3]`

### Remove Duplicates from an Array with NULLs

Deduplicate the contents of the array. In this case, the array contains NULLs.

```sql
SELECT ARRAY_DISTINCT(ARRAY[1,2,NULL,2,3,NULL,1]);
```

Output: `[1,2,NULL,3]`

## ARRAY_INTERSECT_DISTINCT_COUNT

Returns the count of distinct elements that are common to both input arrays as an `INT` value. The function applies set semantics, collapsing duplicate elements within each array before computing the intersection. Both arrays must have the same element type.

If both array arguments are `NULL`, the function returns `NULL`. If one argument is `NULL` and the other is a non-NULL array, the function returns `NULL`. If both arrays are empty, the function returns `0`. NULL elements within arrays participate in the intersection (a NULL in both arrays counts as one shared element).

### Syntax

```sql
ARRAY_INTERSECT_DISTINCT_COUNT(array1, array2)
```

© 2026 Ocient, Inc

| Argument | Data Type | Description |
| --- | --- | --- |
| `array1` | Array | An array of elements. Supported element types are: `INT`, `BIGINT`, `SMALLINT`, `BYTE`, `FLOAT`, `DOUBLE`, `DECIMAL`, `BOOLEAN`, `VARCHAR`, `TIMESTAMP`, `TIME`, `DATE`, `BINARY`, `IPV4`, `IP`, `UUID`, `HASH`, `ST_POINT`, `ST_LINESTRING`, and `ST_POLYGON`. |
| `array2` | Array | An array of elements with the same element type as `array1`. |

## Examples

### Count Shared Elements Between Two Arrays

Count the distinct elements shared between two integer arrays. Both arrays contain `1` and `2`, so the result is `2` even though duplicates are present.

SQL

```
SELECT ARRAY_INTERSECT_DISTINCT_COUNT(
    ARRAY[1, 2, 2, 1],
    ARRAY[1, 2, 2, 3]
);
```

Output: `2`

### Count Shared Elements with No Overlap

Count the distinct elements shared between two arrays that have no elements in common.

SQL

```
SELECT ARRAY_INTERSECT_DISTINCT_COUNT(
    ARRAY[1, 2, 3],
    ARRAY[4, 5, 6]
);
```

Output: `0`

### Count Shared Elements with an Empty Array

When one array is empty, no elements are shared.

```sql
SELECT ARRAY_INTERSECT_DISTINCT_COUNT(
    ARRAY[1, 2, 3],
    INT[]()
);
```

Output: `0`

## ARRAY_LENGTH

Returns the length of the array for the specified dimension. If the array is a nested array, the function returns the length of the outermost array.

### Syntax

```sql
ARRAY_LENGTH(input_array)
```

| Argument | Data Type | Description |
|---|---|---|
| `input_array` | ARRAY | The array that contains any type of elements. The array can be single or multi-dimensional. |

### Example

Return the length of the array.

```sql
SELECT ARRAY_LENGTH(ARRAY[1,2]);
```

Output: `2`

# ARRAY_SORT

Sorts and returns the input array based on the natural ordering of its elements. The behavior of this function varies depending on the syntax you use.

### Syntaxes

### Basic Array Sort

Sorts and returns the input array based on the natural ordering of its elements. If one of the array elements is NULL, then this function sorts the NULL values to the end of the array.

SQL

```
ARRAY_SORT(input_array)
```

| Argument | Data Type | Description |
|---|---|---|
| `input_array` | ARRAY | An array of elements with these types: `BIGINT`, `BOOLEAN`, `BYTE`, `DATE`, `DOUBLE`, `FLOAT`, `INT`, `SMALLINT`, `UUID`, or `VARCHAR`. |

### Sort an Array With a Lambda Function

Sorts and returns the input array based on the results of the specified Lambda function. The function should have two arguments representing two elements of the array. This function should return a negative integer, 0, or a positive integer if the first element is less than, equal to, or greater than the second element, respectively.

SQL

```
ARRAY_SORT(input_array,function)
```

| Argument | Data Type | Description |
|---|---|---|
| `input_array` | ARRAY | An array that contains any type of elements. The array can be single or multi-dimensional. |
| `function` | FUNCTION | This is an optional argument. A lambda function with the format `(x T, y T) -> INT` or another SQL reference |

| Argument | Data Type | Description |
| --- | --- | --- |
| | | function. |

> The Ocient System supports this syntax with the data pipeline functionality only. For details, see **Transform Data in Data Pipelines**.

### Sort an Array in the Specified Order

Determines how the array handles the order of elements in the array.

SQL

```
ARRAY_SORT(input_array,sort_order)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `input_array` | ARRAY | An array of elements with these types: `BIGINT`, `BOOLEAN`, `BYTE`, `DATE`, `DOUBLE`, `FLOAT`, `INT`, `SMALLINT`, `UUID`, or `VARCHAR`. |
| `sort_order` | BOOLEAN | This is an optional argument.<br><br>Determines the sort order of the array. The value `true` means ascending order. The value `false` means descending order. The default value is `true`. |

### Sort an Array in the Specified Order with NULL Elements

Determines how the array handles the order of elements in the array and where NULL elements appear.

SQL

```
ARRAY_SORT(input_array,sort_order,nulls_first)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `input_array` | ARRAY | An array of elements with these types: `BIGINT`, `BOOLEAN`, `BYTE`, `DATE`, `DOUBLE`, `FLOAT`, `INT`, `SMALLINT`, `UUID`, or `VARCHAR`. |

| Argument | Data Type | Description |
| --- | --- | --- |
| `sort_order` | BOOLEAN | This is an optional argument.<br><br>Determines the sort order of the array. The value `true` means ascending order. The value `false` means descending order. The default value is `true`. |
| `nulls_first` | BOOLEAN | This is an optional argument.<br><br>Determines whether NULL elements appear first or last in the array. The `true` value means that NULLs appear first in the array. The `false` value means that they appear last. If the array is in ascending order, the default value is `false`. Otherwise, the default value is `true`. |

## Examples

### Sort an Array

Sort an array of three elements `[2,3,1]`.

SQL

```
SELECT ARRAY_SORT(ARRAY[2,3,1]);
```

Output: `[1,2,3]`

### Sort an Array by Specifying the Sort Order

Sort an array of four elements `[2,3,1,NULL]` and specify the order of the elements in descending order.

SQL

```
SELECT ARRAY_SORT(ARRAY[2,3,1,NULL],false);
```

Output: `[NULL,3,2,1]`

### Sort an Array by Specifying the Sort Order and NULL Placement

Sort an array of four elements `[2,NULL,3,1]` and specify the order of the elements in ascending order, and have the NULL element appear last.

```sql
SELECT ARRAY_SORT(ARRAY[2,NULL,3,1],true,false);
```

Output: `[1,2,3,NULL]`

# ARRAY_TRANSFORM

Transforms one or more arrays based on the logic in a lambda expression that also receives the elements at the same position in every array. Use this function to transform every element in a single array, or to combine corresponding elements from multiple arrays element-wise.

The first one or more arguments are expressions that evaluate to arrays that contain elements to transform. The last argument is a lambda expression or other reference function that defines how to transform each element using the elements at the same position in every array.

The last argument must be of the form `(x1 [T1], ..., xN [TN]) -> U`. This form returns a value of type `U` from the elements `x1` through `xN` at the same position in each of the `N` array arguments. Declaring the type of each element is optional. If you omit a type, the system infers it from the corresponding array argument. If you declare a type, it must match the element type of the corresponding array.

The last argument can also be a reference to an existing function whose signature accepts one argument for each array argument.

The `ARRAY_TRANSFORM` function returns an array with the length of the longest input array. The returned array has the type returned by the lambda function. If the input arrays are not the same length, the system pads the shorter arrays with `NULL` values. If any input array is `NULL`, the result is `NULL`. For multi-dimensional arrays, the function applies to the outermost dimension. You can nest `ARRAY_TRANSFORM` functions to apply them over inner dimensions.

### Syntax

```sql
ARRAY_TRANSFORM(array1 [, array2, ...], function)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `array1` | Array | The array can be single or multi-dimensional. The `ARRAY_TRANSFORM` function only iterates over the first dimension. Provide additional array arguments to combine elements from multiple arrays. |
| `function` | Lambda function `(x1 [T1], ..., xN [TN]) -> U` or Reference function | A lambda function (e.g., `(a, b) -> a + b`) that takes one element from each array argument and returns a value of type `U`. The optional `T1` through `TN` values are the declared types of `x1` through `xN`; if you omit a type, the system infers it from the corresponding array argument. You can also pass a reference function with a matching signature that accepts one argument for each array. |

## Examples

### Transform a Single Array Using a Lambda Function

Use the `ARRAY_TRANSFORM` function to convert each element of an array to uppercase.

SQL

```
SELECT ARRAY_TRANSFORM(ARRAY['alice', 'bob', 'carol'], (x CHAR) -> UPPER(x));
```

Output: `["ALICE", "BOB", "CAROL"]`

### Transform a Single Array Using a Reference Function

Use the `UPPER` function as a reference function with the `ARRAY_TRANSFORM` function.

SQL

```
SELECT ARRAY_TRANSFORM(ARRAY['alice', 'bob', 'carol'], UPPER);
```

Output: `["ALICE", "BOB", "CAROL"]`

### Combine Elements from Two Arrays

Use the `ARRAY_TRANSFORM` function with two arrays to add the corresponding elements together.

SQL

```
SELECT ARRAY_TRANSFORM(
    ARRAY[CAST(1 AS BIGINT), CAST(2 AS BIGINT), CAST(3 AS BIGINT)],
    ARRAY[CAST(10 AS BIGINT), CAST(20 AS BIGINT), CAST(30 AS BIGINT)],
    (a BIGINT, b BIGINT) -> a + b
);
```

Output: `[11, 22, 33]`

### Use a Reference Function with Multiple Arrays

Use the `POWER` function as a reference function with the `ARRAY_TRANSFORM` function to raise each base to the corresponding exponent from a second array. The `POWER` function accepts two numeric arguments, matching the required signature where the first argument is the element from the first array and the second argument is the element from the second array.

SQL

```
SELECT ARRAY_TRANSFORM(
    ARRAY[2, 3, 4],
    ARRAY[2, 2, 2],
    POWER
);
```

Output: `[4, 9, 16]`

## ARRAY_TRANSFORM_WITH_ORD

Transforms an array based on the logic in a lambda expression that also receives the 1-based ordinal of each element. Use this function when the transformation depends on the position of the element in the array, such as generating sequence numbers, weighting elements by index, or pairing elements with their position.

The first argument is an expression that evaluates to an array that contains elements to transform. The second argument is a lambda expression or other reference function that defines how to transform each element using both its value and its position.

The second argument must be of the form `(x T, ord INT) -> U`. This form returns a value of type `U` for an element `x` at 1-based position `ord`. The lambda function specifies the type `T` of the element `x`. The ordinal variable always has the `INT` type. If the lambda function declares a type for the ordinal variable, it must be `INT`.

The second argument can also be a reference to an existing function whose signature accepts the element type followed by a trailing `INT` argument.

The `ARRAY_TRANSFORM_WITH_ORD` function returns an array of elements with the same length as the array argument. The returned array has the type returned by the lambda function. If the input array is `NULL`, the result is `NULL`. For multi-dimensional arrays, the function applies to the outermost dimension. You can nest `ARRAY_TRANSFORM_WITH_ORD` functions to apply them over inner dimensions.

### Syntax

SQL

```
ARRAY_TRANSFORM_WITH_ORD(array, function)
```

| Argument | Data Type | Description |
|---|---|---|
| `array` | Array | The array can be single or multi-dimensional. The `ARRAY_TRANSFORM_WITH_ORD` function only iterates over the first dimension. |
| `function` | Lambda function `(x T, ord INT) -> U`<br>or<br>Reference function | A lambda function (e.g., `(elem INT, ord INT) -> elem * ord`) that takes an element of type `T` and the 1-based `INT` ordinal, and returns a value of type `U`. The return type can be the same type as `T` or a different type. You can also pass a reference function with a matching `(T, INT) -> U` signature. |

### Examples

#### Prefix Each Element with Its Position

Use the `ARRAY_TRANSFORM_WITH_ORD` function with a lambda function that prepends the 1-based position of each element.

```sql
SELECT ARRAY_TRANSFORM_WITH_ORD(
    ARRAY['alice', 'bob', 'carol'],
    (elem CHAR, ord INT) -> CONCAT(CAST(ord AS CHAR), '. ', elem)
);
```

Output: `["1. alice", "2. bob", "3. carol"]`

### Multiply Each Element by Its Position

Use the `ARRAY_TRANSFORM_WITH_ORD` function with a literal array to multiply each element by its 1-based position.

```sql
SELECT ARRAY_TRANSFORM_WITH_ORD(
    ARRAY[10, 20, 30],
    (elem BIGINT, ord INT) -> elem * CAST(ord AS BIGINT)
);
```

Output: `[10, 40, 90]`

### Use a Reference Function

Use the `POWER` function as a reference function with the `ARRAY_TRANSFORM_WITH_ORD` function. The `POWER` function accepts two numeric arguments, matching the required `(T, INT) -> U` signature where the first argument is the element value and the second argument is the 1-based ordinal.

```sql
SELECT ARRAY_TRANSFORM_WITH_ORD(
    ARRAY[2, 3, 4],
    POWER
);
```

Output: `[2, 9, 256]`

# JACCARD_SIMILARITY

Returns the Jaccard similarity coefficient of two arrays as a `DOUBLE` value between `0.0` and `1.0`. The Jaccard similarity measures the size of the intersection divided by the size of the union of the two sets: |A intersect B| / |A union B|. The function applies set semantics, collapsing duplicate elements within each array before computing the result. Both arrays must have the same element type.

A result of `1.0` means that the two arrays contain the same distinct elements. A result of `0.0` means that the two arrays share no elements.

If both array arguments are empty, the function returns `1.0`. If one array is non-empty and the other is empty, the function returns `0.0`. If both array arguments are `NULL`, the function returns `NULL`. NULL elements within arrays participate in the similarity calculation.

### Syntax

```
SQL

JACCARD_SIMILARITY(array1, array2)
```

| Argument | Data Type | Description |
|---|---|---|
| `array1` | Array | An array of elements. Supported element types are: `INT`, `BIGINT`, `SMALLINT`, `BYTE`, `FLOAT`, `DOUBLE`, `DECIMAL`, `BOOLEAN`, `VARCHAR`, `TIMESTAMP`, `TIME`, `DATE`, `BINARY`, `IPV4`, `IP`, `UUID`, `HASH`, `ST_POINT`, `ST_LINESTRING`, and `ST_POLYGON`. |
| `array2` | Array | An array of elements with the same element type as `array1`. |

### Examples

#### Compute Jaccard Similarity of Overlapping Arrays

Compute the Jaccard similarity of two arrays that share some elements. The distinct elements of the first array are `{1, 2, 3}` and the second are `{2, 3, 4}`. The intersection is `{2, 3}` (size two) and the union is `{1, 2, 3, 4}` (size four), so the Jaccard similarity is 2/4 = 0.5.

SQL

```
SELECT JACCARD_SIMILARITY(
    ARRAY[1, 2, 3],
    ARRAY[2, 3, 4]
);
```

Output: `0.5`

### Compute Jaccard Similarity of Identical Arrays

When both arrays contain the same distinct elements, the result is `1.0`.

SQL

```
SELECT JACCARD_SIMILARITY(
    ARRAY[1, 2, 2, 1],
    ARRAY[1, 2]
);
```

Output: `1.0`

### Compute Jaccard Similarity with Duplicates

The distinct elements of the first array are `{1, 2}` and the second one are `{1, 2, 3}`. The intersection is `{1, 2}` (size two) and the union is `{1, 2, 3}` (size three), so the result is approximately 0.667.

SQL

```
SELECT JACCARD_SIMILARITY(
    ARRAY[1, 2, 2, 1],
    ARRAY[1, 2, 2, 3]
);
```

Output: `0.6666666666666666`

### Compute Jaccard Similarity with No Overlap

When the two arrays share no elements, the result is `0.0`.

SQL

```
SELECT JACCARD_SIMILARITY(
    ARRAY[1, 2, 3],
    ARRAY[4, 5, 6]
);
```

Output: `0.0`

# UNNEST

Expands each element in an input array into an individual row.

For example, the `UNNEST` function on an array column of type `ARRAY(INT)` with values `[2, 6]` yields two result rows with integers `2` and `6`.

The values of the other columns in each input row are unchanged in each corresponding output row. You can specify multiple array columns to unnest the specified arrays from each row in parallel.

### Syntax

SQL

```
UNNEST( array_column [, ... ] )
   [ WITH <unnest_options> ]

<unnest_options> ::=
   { ORDINALITY [ ord_identifier ]
   | VALUE [ val_identifier ]
   | NULL_INPUT }
```

| Argument | Data Type | Description |
|---|---|---|
| `array_column` | `ARRAY` | The array column to expand. |
| `ord_identifier` | `CHAR` | When you use this argument in an `ORDINALITY` clause, the argument is the name for the output column. |
| `val_identifier` | `CHAR` | When you use this argument in a `VALUE` clause, the argument is the name for the unnested column. |

The `UNNEST` function supports these options. When you use only one of these options, enclosing the option in parentheses is optional. However, if you use more than one of these options, you must enclose them in parentheses.

| Options | Description |
|---|---|
| `ORDINALITY [ord_identifier]` | Optional.<br>Generates a new integer column that corresponds to the index position of each output element in the original array. The `ord_identifier` value specifies the name of the output ordinality column.<br>If you do not specify this clause, the column name defaults to the original column name with the suffix `_ord`. |
| `VALUE [val_identifier]` | Optional.<br>Rename the unnested column to the new name specified in the `val_identifier` argument.<br>If you do not specify this clause, the column name defaults to the original column name with the suffix `_val`. |
| `NULL_INPUT` | Optional.<br>When the input column array is empty or NULL, this clause specifies to replace each output row with an array with one NULL element. This replacement preserves the contents of other input rows. By default, this option is not enabled. |

These examples demonstrate how the `UNNEST` function operates on arrays and other objects. Most of the examples use the data rows from this table.

Text

```
a   b        c        d     e      f
-------------------------------------------
1   [1, 2]   [6, 9]   []    NULL   [[1, 2], [5], []]
2   [7, 5]   [4]      [3]   [8]    [[6], [9, 4, 7], [3, 8]]
```

## Examples

### Expand a Column

This example performs a simple `UNNEST` on column `b`.

SQL

```
SELECT UNNEST(b);
```

*Output*

Text

```
b_val
-----------
1
2
7
5
```

### Expand a Column Using the `ORDINALITY` Option

In this example, the `ORDINALITY` option adds a second return column that represents the index position of the value in the input array.

SQL

```
SELECT UNNEST(b) WITH ORDINALITY;
```

*Output*

Text

```
b_val   b_ord
--------------------
1       1
2       2
7       1
5       2
```

### Expand a Column with Empty Data

In this example, the `UNNEST` query returns only one row because one of the two rows in column `d` is an empty array.

If you use the `NULL_INPUT` option, the query returns a second row with the `NULL` value.

SQL

```
SELECT UNNEST(d);
```

*Output*

Text

```
d_val
------------
3
```

### Expand a Column with NULL Data

`UNNEST` also does not return array values that are `NULL` unless you specify the `NULL_INPUT` option.

SQL

```
SELECT UNNEST(e);
```

*Output*

Text

```
e_val
------------
8
```

### Expand a Column with Multiple Array Layers

The `UNNEST` function expands only one array layer.

ⓘ The empty array remains in the returned values.

SQL

```
SELECT UNNEST(f);
```

*Output*

Text

```
f_val
------------
[1,2]
[5]
[]
[6]
[9,4,7]
[3,8]
```

### Expand Columns Using Multiple `UNNEST` Statements

Multiple `UNNEST` statements in a query produce a per-row Cartesian product of all the unnested values.

SQL

```
SELECT UNNEST(b), UNNEST(c);
```

*Output*

Text

```
b_val   c_val
------------
1       6
1       9
2       6
2       9
7       4
5       4
```

### Expand Columns Using Multiple `UNNEST` Statements in Reverse Order

This example uses `UNNEST` on the same columns but in reverse order.

SQL

```
SELECT UNNEST(c), UNNEST(b);
```

*Output*

Text

```
c_val   b_val
------------
6       1
6       2
9       1
9       2
4       7
4       5
```

### Expand Multiple Columns

In this example, the query unnests two array columns in parallel. Even though it does not include the `NULL_INPUT` option, the query still returns NULL for column `c` to correspond with column `b`.

SQL

```
SELECT UNNEST(b, c);
```

*Output*

Text

```
b_val   c_val
------------
1       6
2       9
7       4
5       NULL
```

### Expand Multiple Array Columns

This query unnests two array columns.

SQL

```
SELECT UNNEST(b, d);
```

*Output*

Text

```
b_val   d_val
------------
1       NULL
2       NULL
7       3
5       NULL
```

### Expand Values of Arrays Within Arrays

This example has two layers of `UNNEST` to capture values of arrays within arrays.

SQL

```
SELECT UNNEST(f_val) FROM (UNNEST(f));
```

*Output*

Text

```
f_val
------------
1
2
5
6
9
4
7
3
8
```

### Expand an Empty Array

This example unnests an empty integer array.

SQL

```
SELECT UNNEST(INT[]());
```

*Output*

Text

```
col_val
------------
```

The query returns a column of type `INT` but no rows.

### Expand an Empty Array Column Without the `NULL_INPUT` Option

This example selects the non-array column `a` and an empty array column. The query returns no rows because empty or `NULL` array values are not returned unless you specify the `NULL_INPUT` option.

```sql
SELECT a, UNNEST(INT[]());
```

*Output*

```
a   col_val
------------
```

### Expand a Column Without the `NULL_INPUT` Option

This query does not include the `NULL_INPUT` option, which causes the result to omit the NULL array values in column `e`.

```sql
SELECT a, UNNEST(e);
```

*Output*

```
a   e_val
------------
1   8
2   8
```

### Expand a Column with the `NULL_INPUT` Option

This query includes the `NULL_INPUT` option, which means that the query returns the NULL values in column `e`.

```sql
SELECT a, UNNEST(e) WITH NULL_INPUT;
```

© 2026 Ocient, Inc

*Output*

Text

```
a   e_val
------------
1   8
1   NULL
2   8
2   NULL
```

### Expand Arrays with NULL Rows

This example attempts to unnest two arrays, one of which is cast as NULL, while the other is empty.

In both cases, the query returns a column of type `INTEGER` with no rows because there are no values to unnest.

SQL

```
SELECT UNNEST(CAST(NULL AS INT[]);

SELECT UNNEST(INT[]());
```

*Output*

Text

```
col_val
------------
```

## ZIP_WITH_ORD

Merges two or more input arrays, element-wise, into a single array using a combining function that also receives the 1-based ordinal of each tuple. Use this function when the combining logic depends on the position of the elements in the arrays. If one array is shorter than the others, the function pads the shorter array with `NULL` values to match the length of the longest array before applying the combining function.

The function returns an array of length `max(length(array1), length(array2), ...)` containing elements of type `V` as returned by the lambda function. If the arrays are not the same length, the system pads shorter arrays with `NULL` values.

The system rewrites the `ZIP_WITH_ORD` function internally to the `ARRAY_TRANSFORM_WITH_ORD` function. The system first merges the input arrays and then applies the ordinal-aware transform to the resulting tuples.

### Syntax

SQL

```
ZIP_WITH_ORD(array1, array2 [, ...], function)
```

| Argument | Data Type | Description |
|---|---|---|
| `array1` | Array | The array can be single or multi-dimensional. The `ZIP_WITH_ORD` function only iterates over the first dimension. |
| `array2` | Array | The array can be single or multi-dimensional. The `ZIP_WITH_ORD` function only iterates over the first dimension. |
| `function` | Lambda function `(a T1, b T2, ord INT) -> V` or reference function | A lambda function for which `a` is the element from `array1`, `b` is the element from `array2`, and `ord` is the 1-based position. The lambda function specifies the types `T1` and `T2` and returns a value of type `V` (e.g., `(a INT, b INT, ord INT) -> a + b + ord`).<br><br>When merging more than two arrays together, add more arguments before `ord` matching the order of the input arrays (e.g., `(a T1, b T2, c T3, ord INT) -> V`). The ordinal variable must always be the last parameter, and its type must be `INT`. You can also pass a reference function with a matching `(T1, T2, INT) -> V` signature. |

### Example

Use the `ZIP_WITH_ORD` function to compute a weighted line total that includes the line number.

SQL

```
SELECT ZIP_WITH_ORD(
    ARRAY[CAST(100 AS BIGINT), CAST(200 AS BIGINT), CAST(300 AS BIGINT)],
    ARRAY[CAST(2 AS BIGINT), CAST(5 AS BIGINT), CAST(1 AS BIGINT)],
    (price BIGINT, qty BIGINT, ord INT) ->
        CONCAT('Line ', CAST(ord AS CHAR), ': ', CAST(price * qty AS CHAR))
);
```

Output: `["Line 1: 200", "Line 2: 1000", "Line 3: 300"]`

## Other Array Functions

| Function | Syntax | Purpose |
|---|---|---|
| Constructor | TYPE[](e1, e2, ..., en) | Construct an array of SQL type TYPE giving the elements. NULL is also supported as an element. |
| Constructor (2) | array[e1, e2, ..., en] | PostgreSQL®-compliant constructor. The type of the array is deduced from the elements. |
| array concatenation | array_cat(array, array) | Concatenate 2 arrays into a new one. |
| array softmax | softmax(array) | Returns the softmax of the array. The array must be one-dimensional and contain float or double values. The system transfers NULL-valued indices as 0.0. |
| array cross entropy loss | cross_entropy_loss(array, array) | Returns the cross entropy loss of two arrays. Both arrays must be one-dimensional and contain float or double values. NULL values do not contribute to the sum. |
| array log loss | log_loss(array, array) | Returns the log loss of two arrays. Both arrays must be one-dimensional and contain float or double values. NULL values do not contribute to the sum. |
| array logits loss | logits_loss(array, array) | Returns the logits loss of two arrays. Both arrays must be one-dimensional and contain float or double values. NULL values do not contribute to the sum. |
| array hinge loss | hinge_loss(array, array) | Returns the hinge loss of two arrays. Both arrays must be one-dimensional and contain float or double values. NULL values do not contribute to the sum. |

© 2026 Ocient, Inc

| Function | Syntax | Purpose |
|---|---|---|
| array sum | array_sum(array) | Returns the sum of the array. The array must be one-dimensional and contain numeric values. NULL values do not contribute to the sum. |
| array min/max | array_min(array), array_max(array) | Returns the corresponding minimum or maximum of the array. This function only considers the first dimension of the array. If the array contains only NULL values, then the function returns NULL. |
| array argmax | array_argmax(array) | Returns the 1-based position (index) of the maximum element in an array. The first element has index 1.<br><br>This function only considers the first dimension of the array. If the array contains only NULL values, then the function returns NULL. |
| array argmin | array_argmin(array) | Returns the 1-based position (index) of the minimum element in an array. The first element has index 1.<br><br>This function only considers the first dimension of the array. If the array contains only NULL values, then the function returns NULL. |
| array casting | cast_to_array(array, format) | Casts the elements of the array to another type, as specified by the format string. The format is: `'ARRAY(INT)'` for an `int` array, `'ARRAY(CHAR)'` for a `char` array, and so on. Currently, only numeric casts are supported. |
| scalar position | array_position(array, scalar, pos = 1 ) | Returns the position of the first matching scalar in the array. pos indicates the position to start searching, if not specified it defaults to 1. |
| array elements positions | array_positions(array, array ) | Same as array_position(). But this looks for all elements stored in the right array and returns their respective positions in the left array. |
| array append | array_append(array, value) | Add value to the back of an array |
| array prepend | array_prepend(value, array) | Add value to the front of an array |
| array remove | array_remove(array, value) | remove value from the array |
| array replace | array_replace(array, old_value, new_value) | replace value by another in an array |
| convert array to string | char(array) | Converts array to its string representation. |

| Function | Syntax | Purpose |
|---|---|---|
| convert array to string | array_to_string(array, delimiter [, nullstr]) | Converts array to a list of elements separated by ‘delimiter’. Nested arrays are flattened. NULL values are either ignored or replaced by *nullstr* if provided. |
| convert string to array | string_to_array(str, format) | Converts the string representation of an array (e.g., `'int[1,2,NULL]'`) into an array. The format string is the same as in cast_to_array. |

## Function Examples

| Function | SQL statement | Result |
|---|---|---|
| type constructor | int[](1,2) | int array with values 1 and 2 |
| constructor with no type | array[1,2] | bigint array with values 1 and 2 |
| array_cat | array_cat(array[2, 3], array[4, 5]) | array[2, 3, 4, 5] |
| array_length | array_length(array[2, 3]) | 2 |
| cast_to_array | cast_to_array(array[2.5, 3.4], ‘ARRAY(INT)‘) | int[](2,3) |
| array_position | array_position(array[1, 2, 1], 1) | 1 |
| | array_position(array[1, 2, 3, 4, 1], 1, 3) | 5 |
| array_positions | array_positions(array[1, 2, 3, 4, 1], 1) | int[](1,5) |
| array_append | array_append(array[1,2], 3) | array[1,2,3] |
| array_prepend | array_prepend(0, array[1,2]) | array[0,1,2] |
| array_remove | array_remove(array[1,2], 1) | array[2] |
| array_replace | array_replace(array[1,2,4],4,3) | array[1,2,3] |
| softmax | softmax(float[](2.0, 2.0, 2.0, NULL, 2.0)) | float[0.25, 0.25, 0.25, 0.0, 0.25] |
| array_sum | array_sum(int[](1, 2, 3)) | 6 |
| array_min | array_min(int[](1, -2, 3)) | -2 |
| array_argmax | array_argmax(int[](1, 3, 2)) | 2 |
| array_argmin | array_argmin(int[](1, 3, 2)) | 1 |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function | SQL statement | Result |
|---|---|---|
| char(<array value>) | char(array[1,2]) | ‘bigint[1,2]‘ |
| array_to_string | array_to_string(int[1,2,3,NULL,5], ’,’, ’*’) | ‘1,2,3,*,5’ |
| string_to_array | string_to_array(‘int[1,2]’, ‘ARRAY(INT)‘) | int[](1,2) |

# Array Operators

Ocient array operators allow you to concatenate and check for containment or overlap of data. Also, you can retrieve specific elements or slices within arrays.

> ⚠ Do not use array operators, including `@>`, `<@`, and `&&`, to evaluate `NULL` values in arrays. For information on how to check for `NULL` values in arrays, see **Array NULL Handling**.

## Contains Operator ( `@>` )

The `@>` operator determines whether a left-side array contains a scalar value or array elements on the right side.

### `@>` Syntax

SQL

```
array @> scalar_or_array
```

| Argument | Data Type | Description |
|---|---|---|
| `array` | `ARRAY` | An array column or expression. |
| `scalar_or_array` | `ARRAY` or any numeric, character, time, or geospatial data type. | A value or an array of values to check whether they are contained in the array. For data types, see **Understanding Data Types**. |

### Examples

These examples use the `@>` operator to test whether the left-side array contains all the elements from the right-side array.

### Array Containment (True Case)

This example returns `true` because all right-side elements are in the left-side array.

```
SQL
SELECT ARRAY[1, 4, 3] @> ARRAY[3, 1];
```

*Output:* `true`

### Array Containment (False Case)

If the right-side array contains at least one value not present in the left-side array, the query returns `false`. In this example, the right-side array has one value, `5`, not present on the left side.

```
SQL
SELECT ARRAY[1, 4, 3] @> ARRAY[3, 1, 5];
```

*Output:* `false`

### Scalar Containment in an Array

This example checks whether a single scalar value is in the left-side array.

```
SQL
SELECT ARRAY[3, 1, 3] @> 1;
```

*Output:* `true`

## Contained In Operator ( `<@` )

The `<@` operator checks whether a right-side array contains all the elements on the left side.

### Syntax

```sql
scalar_or_array <@ array
```

| Argument | Data Type | Description |
|---|---|---|
| `array` | `ARRAY` | An array column or expression. |
| `scalar_or_array` | `ARRAY` or any numeric, character, time, or geospatial data type. | A value or an array of values to check whether they are contained in the array. For data types, see **Understanding Data Types**. |

### Examples

#### Array Contained Within Another Array (True Case)

This example returns `true` because all left-side elements are in the right-side array.

```sql
SELECT VARCHAR[]('apples', 'oranges') <@ VARCHAR[]('apples', 'oranges', 'bananas')
```

*Output:* `true`

#### String Membership Check

`<@` and other array operators can check whether individual strings are present in an array. The `'oranges'` string is present in the right-side array.

```sql
SELECT 'oranges' <@ VARCHAR[]('apples', 'oranges', 'bananas')
```

*Output:* `true`

## Overlap Operator ( `&&` )

The overlap operator `&&` determines whether any elements between two arrays are common.

### Syntax

```
SQL

array1 && array2
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `array1` | `ARRAY` | An array column or expression to check whether any of its values are shared with `array2`. |
| `array2` | `ARRAY` | An array column or expression to check whether any of its values are shared with `array1`. |

### Examples

#### Check Overlap Between Arrays (True Case)

As long as at least one value is present in both arrays, the `&&` operator returns `true`. Both of these arrays contain the value `3`.

```
SQL

SELECT ARRAY[1 ,2, 3] && ARRAY[3 ,4, 5];
```

*Output:* `true`

#### Check Overlap Between Arrays (False Case)

Both of these arrays have no values in common, so the `&&` operator returns `false`.

```
SQL

SELECT ARRAY[1 ,2, 3] && ARRAY[4 ,5, 6];
```

*Output:* `false`

## Slice Operator ( `:` )

The slice operator `:` returns a subarray ranging from a left index to a right index, both of which are optional to specify. If you exclude both indexes, the slice operator returns the full array.

### Syntax

```
SQL

array[left_index:right_index]
```

| Argument | Data Type | Description |
|---|---|---|
| `array` | `ARRAY` | An array column or expression. |
| `left_index` | `INT` | Optional.<br><br>A starting index for the slice operator to begin the subarray. Index values start at `1`.<br><br>If you do not specify a left index, or if this value is less than zero, then the slice starts at index `1`. |
| `right_index` | `INT` | Optional.<br><br>An ending index for the slice operator to end the subarray. Index values start at `1`.<br><br>If you do not specify a right index or if the value exceeds the array length, the right index defaults to the array length. |

The slice operator also follows these rules:

- Each index starts at `1`.
- If the array or either index value is NULL, the result of slicing is NULL.
- Ranges completely out of array bounds return an empty array. For example, `array[1, 2][4:5] = []`.
- Sequential slices slice each dimension of multidimensional arrays. For example, `ARRAY[ARRAY[1, 2, 3], ARRAY[4, 5, 6]][1:1][2:3] = ARRAY[ARRAY[2,3]]`.
- More than N sequential slices of an N-dimensional array, for example, three sequential slices on a two-dimensional array return an empty array. For example, `ARRAY[1, 2, 3][:][:] = []`.

© 2026 Ocient, Inc

- You cannot combine slicing with the access operator when slicing multidimensional arrays. Any access operator `[n]` converts to `[:n]`. For example, `Array_Val[4][1:6]` would be equivalent to `Array_Val[:4][1:6]`.
- Slicing an array of tuples such as `ARRAY[TUPLE<<INT,INT>>(1,2), TUPLE<<INT,INT>>(3,4)][1:1][2:3]` slices `[1:1]` on the array and `[2:3]` on the tuple elements within the sliced array, and returns the value `TUPLE<<INT>>[TUPLE<<INT>>(2)]`.

### Examples

#### Basic Array Slicing

Slice an array with four numbers starting at index `2` and ending at index `3`.

SQL

```
SELECT ARRAY[1 ,2, 3, 4][2:3];
```

*Output: *`['2','3']`

#### Array Slicing With No Right Index

The query returns all values after the second value because it does not specify an ending index.

SQL

```
SELECT ARRAY[1 ,2, 3, 4][2:];
```

*Output: *`['2','3','4']`

#### Array Slicing With No Left Index

This query captures a subarray starting at the first index because it does not specify a starting value.

SQL

```
SELECT ARRAY[1 ,2, 3, 4][:3];
```

*Output: * `['1','2','3']`

## Array NULL Handling

Filtering with array functions can have different outcomes if they operate on an array containing NULL values or a NULL value of array type.

Array comparison operators, such as `@>`, `<@`, and `&&`, do not follow normal Boolean logic when evaluating NULL values. To evaluate arrays for NULL values, use the filter functions `FOR_ALL()` or `FOR_SOME()`. For details about these functions, see **Array Filters**.

### Examples

#### Evaluate a Single Array With No NULL Values

This example evaluates to `false` because none of the array values are NULL.

SQL

```
SELECT FOR_SOME(ARRAY[1, 2, 3]) IS NULL;
```

*Output: * `false`

#### Evaluate a Single Array With NULL Values

This example evaluates to `true` because the array contains a NULL value.

SQL

```
SELECT FOR_SOME(ARRAY[1, 2, NULL]) IS NULL;
```

*Output: * `true`

#### Select Only Arrays Containing NULL Values

To further demonstrate array NULL behavior, these examples use this table loaded with a few array values, some of which are NULL or contain NULL values.

SQL

```
CREATE TABLE demo_array_table (
    id INT,
    tags VARCHAR[]
);

INSERT INTO demo_array_table (id, tags) VALUES
    (1, VARCHAR[]('alpha', 'beta', 'gamma')),              -- Regular array
    (2, VARCHAR[]('delta', NULL, 'epsilon')),              -- Array containing a N
    (3, NULL),                                             -- Entirely NULL array
    (4, VARCHAR[]()),                                      -- Empty array
    (5, VARCHAR[](NULL, NULL));                            -- Array containing all
```

In this example, the query uses a `FOR_SOME` function to filter the rows to return only arrays with NULL values. The output does not include the third row of the table because the row itself is NULL, and is not an array containing NULL values.

SQL

```
SELECT id, tags FROM demo_array_table
    WHERE FOR_SOME(tags) IS NULL;
```

*Output*

SQL

```
| id | tags                            |
|----|---------------------------------|
|  2 | ['delta', NULL, 'epsilon']      |
|  5 | [NULL, NULL]                    |
```

### Select NULL Values or Arrays Containing NULL Values

This example includes an additional filter to include any NULL rows and arrays with NULL values.

The example uses the `demo_array_table` table, which has values that are NULL or contain NULL values.

SQL

```
SELECT id, tags FROM demo_array_table
    WHERE FOR_SOME(tags) IS NULL
    OR tags IS NULL;
```

*Output*

SQL

```
| id | tags                          |
|----|-------------------------------|
|  3 | NULL                          |
|  5 | [NULL, NULL]                  |
|  2 | ['delta', NULL, 'epsilon']    |
```

### Select Arrays Without NULL Values

This example filters the rows using the `FOR_ALL` filter function to return only arrays with no NULL values. The output also contains rows with empty arrays.

The example uses the `demo_array_table` table, which has values that are NULL or contain NULL values.

SQL

```
SELECT id, tags FROM demo_array_table
    WHERE FOR_ALL(tags) IS NOT NULL;
```

*Output*

SQL

```
| id | tags                          |
|----|-------------------------------|
|  4 | []                            |
|  1 | ['alpha', 'beta', 'gamma']    |
```

### Select Only Non-Empty Arrays Without NULL Values

To omit empty arrays, you can add a filter to check the array length. The `ARRAY_LENGTH` function removes any empty arrays.

This example uses the `demo_array_table` table, which has values that are NULL or contain NULL values.

SQL

```
SELECT id, tags FROM demo_array_table
    WHERE FOR_ALL(tags) IS NOT NULL
    AND ARRAY_LENGTH(tags) > 0;
```

*Output*

SQL

```
| id | tags                          |
|----|-------------------------------|
|  1 | ['alpha', 'beta', 'gamma']    |
```

# Multidimensional Arrays

Multidimensional arrays are supported. As seen in these examples, each dimension, or length, at each level does not have to be the same. NULL values are allowed at each dimension of an array.

### Multidimensional Examples

| Function | SQL statement | Result |
|---|---|---|
| type constructor two-dimensional | `int[][](int[](1, NULL), array[1])` | two-dimensional `INT` array with values `[1, NULL]` and `[1]` |
| constructor with no type two-dimensional | `array[int[]\(1), array[int(2)]]` | two-dimensional `INT` array with values `[1]` and `[2]` |
| two-dimensional array with NULL values | `array[array[1, NULL], NULL]` | two-dimensional `BIGINT` array with values `[1, NULL]` and `NULL` |
| two-dimensional array with different lengths | `array[array[1], array[1,2], array[1,2,3]]` | two-dimensional `BIGINT` array with values `[1]`, `[1,2]`, and `[1,2,3]` |

# Character and Binary Functions

Reference for Ocient SQL character and binary functions for string manipulation, encoding, decoding, padding, regular expressions, and byte-level operations.

All string functions support Unicode characters. Functions that transform character case are locale-sensitive.

These functions support the UTF-8 format:

- RTRIM
- LTRIM
- LEFT
- RIGHT
- TRIM
- TRANSLATE
- RPAD
- LPAD
- SUBSTRING

Index position values for character and string functions begin at position `1`. For example, the `"H"` in the string `"Hello"` is at position `1`.

## ASCII

Returns the ASCII code value of the leftmost character of the character value.

The ASCII function only supports ASCII characters in the input argument.

### Syntax

SQL

```
ASCII(char)
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### Example

```sql
SELECT ASCII('a');
```

*Output: * `97`

### Example

```sql
SELECT ASCII('bc');
```

*Output: * `98`

## BIT_LENGTH

Returns the length of the character value in bits.

### Syntax

```sql
BIT_LENGTH(char)
```

### Example

```sql
SELECT BIT_LENGTH('a');
```

*Output: * `8`

### Example

```sql
SELECT BIT_LENGTH('ab');
```

*Output: * `16`

**Example**

```sql
SELECT BIT_LENGTH('ab4');
```

*Output: * `24`

## BTRIM

Alias for **TRIM**.

## CHR

Converts an integer value to a string.

The value is first sign-extended to eight bytes. Then, if it can be represented as one byte, a string is returned with that one byte.

Otherwise, a string is returned of length two bytes, four bytes, or eight bytes with the bytes set to the big-endian representation of the integer, depending on how many high order zero bytes there are in the integer.

**Syntax**

```sql
CHR(integer)
```

**Example**

```SQL
SELECT CHR(97);
```

*Output: * `a`

## CHAR_LENGTH

Alias for **LENGTH**.

## CHARACTER_LENGTH

Alias for **LENGTH**.

## CONCAT

Concatenates two or more values, all of which must be binary, hash, or string data types.

For strings, as long as one argument is a character value, the other arguments are implicitly cast to a character value.

### Syntax

```SQL
CONCAT(value1, value2 [, ...])
```

| Arguments | Data Type | Description |
|---|---|---|
| `value1, value2 [, ...]` | `BINARY`, `HASH`, or `CHAR` | Two or more values to concatenate.<br>If any argument is a character value, the others are also cast to a character value. |

### Example

```SQL
SELECT CONCAT('ocient',' ','data', ' ', 'warehouse');
```

*Output: * `ocient data warehouse`

### Example

```
SQL

SELECT 'ocient'||' data warehouse';
```

*Output: * `ocient data warehouse`

## ENDSWITH

Returns `true` if `x` ends with `y` and `false` otherwise.

### Syntax

```
SQL

ENDSWITH(char1, char2)
```

| Argument | Data Type | Description |
|---|---|---|
| `char1` | `CHAR` | A string to evaluate for whether it ends with `char2`. |
| `char2` | `CHAR` | A string to evaluate for whether `char1` ends with it as a substring. |

### Example

```
SQL

SELECT ENDSWITH('ocient data warehouse','warehouse');
```

*Output: * `true`

### Example

```sql
SELECT ENDSWITH('ocient data warehouse','db');
```

*Output: * `false`

### Example

```sql
SELECT ENDSWITH('tamaño','o');
```

*Output: * `true`

## INITCAP

For each word in the specified string, capitalize the first character if it is alphabetic. The system defines words as alphanumeric strings separated by non-alphanumeric characters. The system converts all other alphabetic characters to lowercase.

### Syntaxes

```sql
INITCAP(char_string)
INITCAP(char_string, delimiter)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `char_string` | `CHAR` | A string to evaluate for initial capitalization. |
| `delimiter` | `CHAR` | Optional.<br>One or more non-alphanumeric characters that specify the delimiter between words. The characters include all the ASCII printable non-alphanumeric characters except backquotes `` ` `` and equals `=`. Non-ASCII characters are not included.<br>ℹIf you specify alphabetic characters for the delimiter, the function converts them to lowercase.<br>**Example**<br>`sql SQL<br />SELECT INITCAP('ocient');<br />`<br>*Output: * `Ocient` |

## INSTR

Returns the index position of the first occurrence where the character value `char_substring` appears in the character value `char` by ignoring the case.

### Syntax

```
SQL

INSTR(char, char_substring)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `char` | `CHAR` | A string to evaluate for the first index position where `char_substring` appears. |
| `char_substring` | `CHAR` | A string to evaluate for where it first appears in `char`. |

### Example

```
SQL

SELECT INSTR('ocient dw dw', 'ocient');
```

*Output: * `1`

```sql
SELECT INSTR('ocient dw dw', 'dw');
```

*Output: * `8`

## JSON_EXTRACT_PATH_TEXT

Returns the value for the key-value pair referenced by a series of path elements in a JSON string.

### Syntax

```sql
JSON_EXTRACT_PATH_TEXT (
    json_string, path [, path2 [, ...] ] [, null_if_invalid ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `json_string` | `CHAR` | A JSON string. |
| `path [, path2 [, ...] ]` | `CHAR` | One or more path elements in a JSON string.<br>You must include at least one path element up to a maximum of five, meaning the function can extract from paths nested up to five levels deep in the JSON string.<br>Path elements are case-sensitive. If a specified path element does not exist in the JSON string, the function returns `NULL`. |
| `null_if_invalid` | `BOOLEAN` | Optional.<br>If you set this value to `TRUE`, the function returns `NULL` if the JSON string is invalid.<br>If you set this value to `FALSE`, the function returns an error when the JSON string is invalid.<br>The default value is `FALSE`. |

### Examples

#### Extract Values from Nested Paths

This example extracts the value based on two specified paths in the JSON string, `n4` and `n6`.

```sql
SELECT JSON_EXTRACT_PATH_TEXT(
    '{"n2":{"n3":1},"n4":{"n5":99,"n6":"circle"}}',
    'n4', 'n6'
    );
```

*Output: * `"circle"`

### Return NULL from Invalid JSON

In this example, the query requests the same nested paths, but the JSON is invalid because all of the keys lack quotation marks.

The query returns `NULL` because the `null_if_invalid` argument equals `TRUE`.

```sql
SELECT JSON_EXTRACT_PATH_TEXT(
    '{n2:{n3:1},n4:{n5:99,n6:"circle"}}',
    'n4', 'n6',
    TRUE
    );
```

*Output: * `NULL`

## LCASE

Alias for **LOWER**.

## LEFT

Return the number of characters in the string equal of the value `integer`. If `integer` is negative, the function returns all but the last `integer` characters.

### Syntax

```sql
LEFT(char, integer)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `char` | `CHAR` | A string to be modified by returning the number of characters equal to `integer`. |
| `integer` | `INT` | The number of characters to return from the `char` string.<br><br>If `integer` is negative, the function returns all but the last `integer` characters. |

### Example

```
SQL
SELECT LEFT('ocient data warehouse', 8);
```

*Output: * `ocient d`

### Example

```
SQL
SELECT LEFT('ocient data warehouse', -3);
```

*Output: * `ocient data wareho`

## LENGTH

Alias for CHAR_LENGTH and CHARACTER_LENGTH.

Returns the length of the value. For character data types, this value is in terms of characters. For binary data types, this value is in terms of bytes.

### Syntax

```
SQL
LENGTH(character_or_binary_value)
```

### Example

```sql
SELECT LENGTH('ocient data warehouse');
```

*Output: * `21`

## LOCATE

Alias for POSITION.

Returns the index position of the first occurrence of the character value `substring` in the character value `string`.

Optionally, you can also include an additional value `offset` to offset the LOCATE function by the specified number of spaces.

Index positions begin at `1`.

### Syntax

```sql
LOCATE(substring, string [, offset] )
```

| Argument | Data Type | Description |
|---|---|---|
| `substring` | `CHAR` | A substring to be found for its first position in string. |
| `string` | `CHAR` | A string to be evaluated for the first position of `substring`. |
| `offset` | `INT` | Optional. A number of index positions in `string` to offset the search for the `substring` value.<br>This index position must be a positive integer, and it starts from the left of `string`. |

### Example

```sql
SELECT LOCATE('ware', 'ocient data warehouse');
```

*Output: * `13`

### Example

```sql
SELECT LOCATE('e', 'ocient');
```

*Output: * `4`

### Example

In this example, the index starts at position 5. This means the function skips the initial `'e'` in the string. Instead, it returns the second `e` at index position 15.

```sql
SELECT LOCATE('e', 'ocient database', 5);
```

*Output: * `15`

## LOWER

Alias for LCASE.

Convert string to lowercase.

### Syntax

```sql
LOWER(char)
```

### Example

```sql
SELECT LOWER('Ocient');
```

*Output: * `ocient`

### Example

```
SQL

SELECT LOWER('OCIENT');
```

*Output: * `ocient`

## LPAD

Pad the input text to the specified length with the pad string on the left side. If text is longer than length, it is truncated to `length` characters. If the argument pad is not provided, the space character is used.

### Syntax

```
SQL

LPAD(string, length [, pad_character] )
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to be padded on its left side with additional characters, so that it equals the `length` value. |
| `length` | `INT` | The number of characters for `string` to total.<br>If the `string` is already longer than `length`, the function truncates `string` to equal the `length` value. |
| `pad_character` | `CHAR` | Optional. A string of one or more characters to use to pad `string` to equal the `length` value.<br>If not provided, `pad_character` uses a whitespace character to pad. |

### Example

```
SQL

SELECT LPAD('ocient data warehouse',30,'ab');
```

*Output: * `abababababaocient data warehouse`

### Example

```
SQL

SELECT LPAD('ocient data warehouse',6);
```

*Output: * `ocient`

## LTRIM

Removes leading blanks from the string value `string`.

Alternatively, you can specify a second string value `trim_character`. If you specify the `trim_character` value, the LTRIM function removes all leading instances of the `trim_character` value from the `string`.

### Syntax

```
SQL

LTRIM(string [, trim_character] )
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to be trimmed on its left side. |
| `trim_character` | `CHAR` | Optional. A string of one or more characters to be trimmed from the left side of `string`. Each character is trimmed individually, not as a cohesive substring.<br>If you do not specify this argument, this value defaults to removing all whitespace from the left side of `string`. |

### Example

```
SQL

SELECT LTRIM(' ocient');
```

*Output: * `ocient`

### Example

```
SQL

SELECT LTRIM('aaaaaocient','a');
```

*Output: * `ocient`

### Example

In this example, all characters `'abeo '` are removed from the left side of the string.

```
SQL

SELECT LTRIM('aaeabe ocient','abeo ');
```

*Output: * `cient`

## MD5

Returns the hexadecimal string (all lowercase) representing the md5 hash of `char`.

### Syntax

```
SQL

MD5(char)
```

### Example

```
SQL

SELECT md5('ocient');
```

*Output: * `438f03cf6e9ddf8793e02db25f2d2f88`

## MID

Alias for **SUBSTRING**.

## OCTET_LENGTH

Returns the length in bytes of a character or binary value.

### Syntax

```SQL
OCTET_LENGTH(value)
```

### Example

```SQL
SELECT OCTET_LENGTH('a');
```

*Output: * `1`

### Example

```SQL
SELECT OCTET_LENGTH('ocient');
```

*Output: * `6`

## POSITION

Alias for **LOCATE**.

## REGEXP_COUNT

Searches a string for all occurrences of a regular expression pattern. The function returns an integer representing the number of times the regular expression pattern occurs in the string.

### Syntax

SQL

```
REGEXP_COUNT( string, pattern [, position [, parameters ] ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | The string to search, specified as a character string. |
| `pattern` | `CHAR` | The regular expression pattern to use in the search, specified as a character string. |
| `position` | `INT` | Optional.<br>The position, specified as a positive integer, that represents the position within the `string` string where to begin the search, based on the number of characters.<br>If this integer exceeds the number of characters in `string`, then the function returns `0`.<br>The default value is `1`. |
| `parameters` | `CHAR` | Optional.<br>Parameters, specified as a character string, that contains one or more characters representing regular expression options for pattern matching. Supported options are:<br>`c` — Perform case-sensitive matching. The Ocient® System enables this type of matching by default.<br>`i` — Perform case-insensitive matching.<br>`p` — Interpret the pattern using the Perl Compatible Regular Expression (PCRE) dialect. For details, see **PCRE**.<br>The Ocient System enables this interpretation by default. |

### Example

This example searches the `'ABABDaSGRESaB'` string for the count of occurrences of the `'AB'` string by ignoring the case sensitivity. The search starts at position `1`.

SQL

```
SELECT REGEXP_COUNT('ABABDaSGRESaB', 'AB', 1, 'i');
```

*Output: * `3`

## REGEXP_INSTR

Searches a string using a regular expression pattern and returns an integer representing the start position or end position of the substring that matches.

The function returns `0` if no match is found.

The `REGEXP_INSTR` function is similar to the **POSITION** function, but it allows greater precision with regular expressions.

### Syntax

SQL

```
REGEXP_INSTR( source_string, pattern [, position [, occurrence] [, option [, parame
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | The string to search, specified as a character string.<br>Note that SQL escape sequences for string literals can override regular expression escape sequences. For details, see **String Literals and Escape Sequences**. |
| `pattern` | `CHAR` | The regular expression pattern to use in the search, specified as a character string. |
| `position` | `INT` | Optional.<br>A positive integer that represents the position within the `string` string where to begin the search, based on the number of characters. This value alters only the start position for the match, not the returned string position.<br>If this integer exceeds the number of characters in `string`, then the function returns `0`.<br>The default value is `1`. |
| `occurrence` | `INT` | Optional.<br>A positive integer that represents the occurrence of a positive pattern match to return.<br>The default value is `1`, which means the function returns the first substring that matches the regular expression pattern. |
| `option` | `INT` | Optional.<br>An integer that specifies whether to return the position of the matching start position or the end position. Your choices are:<br>* `0`: Returns the start position of the match.<br>* `1`: Returns the end position of the match `+1`.<br>The function treats any nonzero integer value as `1`.<br>The default value is `0`. |

| Argument | Data Type | Description |
|---|---|---|
| `parameters` | `CHAR` | Optional.<br>A string containing one or more characters that represents the regular expression options for pattern matching.<br>Supported options are:<br>`c` — Perform case-sensitive matching. The Ocient System enables this type of matching by default.<br>`i` — Perform case-insensitive matching.<br>`e` — Extract the substring using a regular expression subpattern. This subpattern is enclosed in parentheses in the regular expression.<br>The function uses the full regular expression pattern for the match but returns only the first subpattern match.<br>`p` — Interpret the pattern using the Perl Compatible Regular Expression (PCRE) dialect. For details, see **PCRE**.<br>The Ocient System enables this interpretation by default. |

### Example

The query searches the website URL for the substring preceded by the `#` character. The function includes optional arguments to start the search at position `9` and match the first occurrence. The last specified optional argument directs the function to return the ending position of the matching substring.

SQL

```
SELECT REGEXP_INSTR(
    'https://docs.ocient.com/character-binary-functions#J28jB',
    '#\w+',
    9,
    1,
    1
    );
```

*Output: * `57`

## REGEXP_REPLACE

Searches a string for all occurrences of a regular expression pattern. The function replaces every match occurrence of the pattern with a new string.

The `REGEXP_REPLACE` function is similar to the **REPLACE** and **TRANSLATE** functions, but it allows greater precision with regular expressions.

## Syntax

```
SQL

REGEXP_REPLACE( string, pattern [, replace_string [ , position [, parameters ] ] ]
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | The string to search, specified as a character string.<br>Note that SQL escape sequences for string literals can override regular expression escape sequences. For details, see **String Literals and Escape Sequences**. |
| `pattern` | `CHAR` | The regular expression pattern to use in the search, specified as a character string. |
| `replace_string` | `CHAR` | Optional.<br>A string to replace all occurrences of the regular expression pattern in `string`.<br>This string can include references to capture groups in the regular expression `pattern`. To reference capture groups, use a `$` followed by the group number. For example, `$1` references the first capture group, and `$2` references the second.<br>The default value is an empty string `''`. |
| `position` | `INT` | Optional.<br>A positive integer that represents the position within the string to begin the search, based on the number of characters.<br>If this integer exceeds the number of characters in `string`, then the function returns the original `string`.<br>The default value is `1`. |
| `parameters` | `CHAR` | Optional.<br>A string containing one or more characters representing regular expression options for pattern matching.<br>Supported options are:<br>`c` — Perform case-sensitive matching. The Ocient System enables this type of matching by default.<br>`i` — Perform case-insensitive matching.<br>`p` — Interpret the pattern using the Perl Compatible Regular Expression (PCRE) dialect. For details, see **PCRE**.<br>The Ocient System enables this interpretation by default. |

## Examples

### Replace Text Using a Substring

The query replaces the matching substring `'#J28jB'` with the characters `'#OFqD_'`. The search begins at position `9`.

```sql
SELECT REGEXP_REPLACE(
    'https://docs.ocient.com/character-binary-functions#J28jB',
    '#\w+',
    '#OFqD_',
    9
    );
```

*Output: * `/character-and-binary-functions`

### Replace Text Using Multiple Capture Groups

This example uses three capture groups to take an unformatted phone number and convert it into the `(XXX) XXX-XXXX` format. The `replace_string` argument references each capture group as `$1`, `$2`, and `$3`.

```sql
SELECT REGEXP_REPLACE(
    '5558675309',
    '(\d{3})(\d{3})(\d{4})',
    '($1) $2-$3'
    );
```

*Output: * `(555) 867-5309`

## REGEXP_SUBSTR

Returns one substring from a string that matches a specified regular expression pattern.

`REGEXP_SUBSTR` is similar to the **SUBSTR** function, but it allows greater precision with regular expressions.

If the pattern produces no matches, the function returns an empty string.

### Syntax

SQL

```
REGEXP_SUBSTR( string, pattern [, position [, occurrence [, parameters ] ] ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | The string to search, specified as a character string.<br>Note that SQL escape sequences for string literals can override regular expression escape sequences. For details, see **String Literals and Escape Sequences**. |
| `pattern` | `CHAR` | The regular expression pattern to use in the search, specified as a character string. |
| `position` | `INT` | Optional.<br>A positive integer that represents the position within the string to begin the search, based on the number of characters.<br>If this integer is greater than the number of characters in `string`, then the function returns the original `string`.<br>The default value is `1`. |
| `occurrence` | `INT` | Optional.<br>A positive integer that represents the occurrence of a positive pattern match to return.<br>If this value exceeds the number of matches, then the function returns NULL.<br>The default value is `1`, which means the function returns the first substring that matches the regular expression pattern. |
| `parameters` | `CHAR` | Optional.<br>A string containing one or more characters representing regular expression options for pattern matching.<br>Supported options are:<br>`c` — Perform case-sensitive matching. The Ocient System enables this type of matching by default.<br>`i` — Perform case-insensitive matching.<br>`e` — Extract the substring using a regular expression subpattern. This subpattern is enclosed in parentheses in the regular expression.<br>The function uses the full regular expression pattern for the match, but it returns only the first subpattern match.<br>If there is no subexpression in the `pattern` argument, then the `e` parameter is ignored.<br>`p` — Interpret the pattern using the Perl Compatible Regular Expression (PCRE) dialect. For details, see **PCRE**.<br>The Ocient System enables this interpretation by default. |

### Example

The query returns the first occurrence of the `#J28jB` string by using the regular expression pattern `'#\w+'`. The search starts at position `9`.

```
SQL

SELECT REGEXP_SUBSTR(
    'https://docs.ocient.com/character-binary-functions#J28jB',
    '#\w+',
    9,
    1
    );
```

*Output: * `#J28jB`

## REPEAT

Repeats the `char` string `num` times without spaces.

### Syntax

```
SQL

REPEAT(char, num)
```

### Example

Repeat the `a` string five times.

```
SQL

SELECT REPEAT('a', 5);
```

*Output: * `aaaaa`

## REPLACE

Replaces all occurrences of `substr_to_remove` in the character value `string` with `substr_to_replace`.

### Syntax

```SQL
REPLACE(string, substr_to_remove, substr_to_replace)
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to alter by replacing all instances of `substr_to_remove` with `substr_to_replace`. |
| `substr_to_remove` | `CHAR` | A substring to remove from `string`, replacing all instances with the `substr_to_replace` value. If `substr_to_remove` is the empty string, the system returns `string`. |
| `substr_to_replace` | `CHAR` | A substring to replace all instances of `substr_to_remove`. |

### Example

```SQL
SELECT REPLACE('abcabcabcabc', 'ab', '$');
```

*Output: * `$c$c$c$c`

## REVERSE

Reverse the input string.

### Syntax

```SQL
REVERSE(char)
```

### Example

```sql
SELECT REVERSE('abcd');
```

*Output: * `dcba`

## RIGHT

Return the number of trailing characters in the string equal to the value `integer`.

### Syntax

```sql
RIGHT(char, integer)
```

| Argument | Data Type | Description |
|---|---|---|
| `char` | `CHAR` | A string to evaluate to return the number of trailing characters equal to `integer`. |
| `integer` | `INT` | The number of characters of return from the end of the `char` string.<br>If `integer` is negative, the function returns all but the first `integer` characters. |

### Example

```sql
SELECT RIGHT('ocient data warehouse', 8);
```

*Output: * `arehouse`

### Example

```sql
SELECT RIGHT('ocient data warehouse', -3);
```

*Output: *`ent data warehouse`

## RPAD

Pad the input text to the specified length with the pad string on the right side. If text is longer than length, it is truncated to `length` characters. If the argument pad is not provided, the space character is used.

### Syntax

SQL

```
RPAD(character_value_text, integral_value_length [, character_value_pad] )
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to be padded on its right side with additional characters, so that it equals the `length` value. |
| `length` | `INT` | The number of characters for `string` to total.<br>If the `string` is already longer than `length`, the function truncates `string` to equal the `length` value. |
| `pad_character` | `CHAR` | Optional. A string of one or more characters to use to pad `string` to equal the `length` value.<br>If not provided, `pad_character` uses a whitespace character to pad. |

### Example

SQL

```
SELECT RPAD('ocient data warehouse',30);
```

*Output: *`ocient data warehouse`

### Example

SQL

```
SELECT RPAD('ocient data warehouse',30,'ab');
```

*Output: * `ocient data warehouseabababababa`

## RSUBSTRING

Returns the substring from the right side of a string, based on a specified length.

### Syntax

```
SQL

RSUBSTRING(string, integer)
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to be evaluated to return a substring based on the `integer` value. |
| `integer` | `INT` | The number of characters to return from the right side of the `string` value.<br>This value must be positive. |

### Example

```
SQL

SELECT RSUBSTRING('ocient data warehouse',14);
```

*Output: * `data warehouse`

## RTRIM

Removes trailing blanks from the string value `string`.

Alternatively, you can specify a second string value `trim_character`. If you specify the `trim_character` value, the RTRIM function removes all trailing instances of the `trim_character` value from the `string`.

### Syntax

```sql
RTRIM(string [, trim_character] )
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to be trimmed on its right side. |
| `trim_character` | `CHAR` | Optional. A string of one or more characters to be trimmed from the right side of `string`. Each character is trimmed individually, not as a cohesive substring.<br>If you do not specify this argument, this value defaults to removing all whitespace from the right side of `string`. |

### Example

```sql
SELECT RTRIM('ocient ');
```

*Output: * `ocient`

### Example

```sql
SELECT RTRIM('ocientaaaaaa','a');
```

*Output: * `ocient`

## SHA1

Uses the [SHA-1](**https://en.wikipedia.org/wiki/SHA-1#:~:text=In%20cryptography%2C%20SHA%2D1%20(,rendered%20as%2040%20hexadecimal%20digits**.) cryptographic hash function to convert a string into a 40-character string representing the hexadecimal value of a 160-bit checksum.

### Syntax

```sql
SHA1(string)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `string` | `CHAR` | A string to convert using the SHA-1 cryptographic hash function. |

### Example

```sql
SELECT SHA1('Ocient');
```

*Output: * `0c2a9a042b9f047f875c3414e7a4f4c53efbe082`

## SPACE

Returns a string of repeated spaces equal to the number value, `repeat`. You can join this to another string by using the **CONCAT** function.

### Syntax

```sql
SPACE(repeat)
```

### Example

```sql
SELECT CONCAT(SPACE(10),'end');
```

*Output: * `end`

## SPLIT_PART

Split the value `string` based on the `delimiter` value. The function returns a substring from the split operation based on the `index` value (starting from 1).

### Syntax

```
SQL

SPLIT_PART(string, delimiter, index)
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to be split based on the `delimiter` value. |
| `delimiter` | `CHAR` | The character to use as a delimiter in `string`. |
| `index` | `INT` | The index of the substring to return. The first index position starts at `1`. |

### Example

```
SQL

SELECT SPLIT_PART('id|name|address','|',1);
```

*Output: * `id`

### Example

```
SQL

SELECT SPLIT_PART('id|name|address','|',2);
```

*Output: * `name`

### Example

```
SQL

SELECT SPLIT_PART('id,name,address',',',3);
```

*Output: * `address`

## SPLIT_TO_ARRAY

Splits a string into an array of substrings.

### Syntax

```
SQL

SPLIT_TO_ARRAY(string, [ delimiter ])
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to split into an array of substrings. |
| `delimiter` | `CHAR` | Optional.<br>The delimiter that divides the string.<br>The default value is a comma ( `,` ). |

### Example

This example specifies `|` as the delimiter to split the input string.

```
SQL

SELECT SPLIT_TO_ARRAY('AB|CD|EF', '|');
```

*Output: * `['AB','CD','EF']`

## STARTSWITH

Returns `true` if `string` starts with `substring` and `false` otherwise.

### Syntax

```
SQL

STARTSWITH(string, substring)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `string` | `CHAR` | A string to search. |
| `substring` | `CHAR` | A substring to find at the beginning of `string`. |

### Example

```
SQL

SELECT STARTSWITH('ocient','o');
```

*Output: *`true`

### Example

```
SQL

SELECT STARTSWITH('ocient','c');
```

*Output: *`false`

## STRPOS

Equivalent to using **LOCATE** as `LOCATE(substring, string)`. Note the reversed argument order.

### Syntax

```
SQL

STRPOS(string, substring)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `string` | `CHAR` | A string to be evaluated for the first position of `substring`. |
| `substring` | `CHAR` | A substring to be found for its first position in `string`. |

### Example

```sql
SELECT STRPOS('ocient data warehouse','house');
```

*Output: * `17`

## SUBSTR

Alias for **SUBSTRING**.

## SUBSTRING

Alias for SUBSTR and MID.

Returns the substring of a character or binary value that starts with the position specified by the second argument and that ends with the position specified by one less than the sum of the second and third arguments. When the sum of the second and third arguments is less than two, the function returns the empty string.

### Syntax

```sql
SUBSTRING(string, start_position [, length] )
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to be truncated based on the `start_position` and `end_position` values. |
| `start_position` | `INT` | The starting position to return a substring. The first index position starts at `1`. |
| `length` | `INT` | Optional. The number of characters from the `start_position` to include in the returned substring. If unspecified, SUBSTRING returns all characters after the `start_position`. |

### Example

```sql
SELECT SUBSTRING('ocient data warehouse',8);
```

*Output: * `data warehouse`

### Example

```sql
SELECT SUBSTRING('ocient data warehouse',8,4);
```

*Output: * `data`

## TO_CHAR

Converts a numeric, date, or timestamp value into a `CHAR` date type.

```sql
TO_CHAR(value, format)
```

| Argument | Data Type | Description |
|---|---|---|
| `value` | `DATE`, `TIMESTAMP`, or all numeric types | A numeric, date, or timestamp value to be converted into a `CHAR` date type. |
| `format` | `CHAR` | The format used for the `CHAR` conversion. For information on data type formats, see the **Formatting Functions** page. |

### Example

```sql
SELECT TO_CHAR(20200610132514/1000000,'9999-99-99');
```

*Output: * `2020-06-10`

### Example

```
SQL

SELECT TO_CHAR(20200610132514%1000000,'99:99:99');
```

*Output: * `13:25:14`

## TRANSLATE

Replaces specified characters in a provided string with a separate set of characters.

Characters specified in the `char_to_remove` set are replaced with characters in the `char_to_replace` set based on the corresponding index position.

### Syntax

```
SQL

TRANSLATE(string, char_to_remove, char_to_replace)
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to have specific characters transposed based on the `char_to_remove` and `char_to_replace` values. |
| `char_to_remove` | `CHAR` | The characters to be removed from `string`. Characters specified in the `char_to_remove` set are replaced with characters in the `char_to_replace` set based on the corresponding index position. If `char_to_remove` is longer than `char_to_replace`, occurrences of the extra characters are removed. |
| `char_to_replace` | `CHAR` | The characters to replace the removed characters in `char_to_remove`. |

### Example

```
SQL

SELECT TRANSLATE('abcdef','ace','ghi');
```

*Output: * `gbhdif`

## TRIM

Alias for BTRIM.

Trim leading and trailing space characters from the string.

Alternatively, you can specify a second string value `trim_char`. If a `trim_char` value is provided, the `TRIM` function removes all leading and trailing instances of the `trim_char` value from the string.

### Syntax

```SQL
TRIM(string [, trim_char] )
```

| Argument | Data Type | Description |
|---|---|---|
| `string` | `CHAR` | A string to be trimmed of leading and trailing space characters, or any other characters specified by the `trim_char` argument. |
| `trim_char` | `CHAR` | Optional. If specified, this removes an alternative substring from the start or end of the `string` value. |

### Example

```SQL
SELECT TRIM(' trimmed string ');
```

*Output: * `trimmed string`

### Example

```SQL
SELECT TRIM('aaaaaaaatrimmed stringaaaaaaaaa', 'a');
```

*Output: * `trimmed string`

## UCASE

Alias for **UPPER**.

## UPPER

Alias for UCASE.

Convert string to upper case.

### Syntax

```SQL
UPPER(character_value)
```

### Example

```SQL
SELECT UPPER('ocient');
```

*Output: * `OCIENT`

## Concatenate Operator( `||` )

The `||` operator concatenates two strings. If you specify a NULL string, the result is NULL.

### `||` Syntax

```SQL
string1 || string2
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `string1` | `CHAR` | A string to concatenate. |
| `string2` | `CHAR` | A string to concatenate with the first string. |

### Examples

#### Concatenate Two Strings

Concatenate two strings.

```
SQL
SELECT 'hello ' || 'world';
```

Output: `'hello world'`

#### Concatenate a NULL String

Concatenate two strings, one of which is NULL.

```
SQL
SELECT NULL || 'world';
```

Output: `NULL`

# Data Types

Reference of Ocient SQL data types, including numeric, character, date and time, boolean, network, geospatial, array, tuple, and matrix data types.

The Ocient® System supports a variety of data types for SQL functions and querying. For information on supported data types, see **Data Types for SQL Functions**. Data type requirements for a specific function can be found in **SQL Reference** section.

SQL statements, such as DDL and DCL commands, use generic data types numeric and string. For details, see **Data Types for SQL Statements**.

## Data Types for SQL Functions

The following data types are supported in table columns and queries.

This table provides more information on the data types supported by the Ocient System. The example value column gives SQL input examples for the respective data types.

The data types in this table apply to SQL functions.

> The default column values for the Tuple, Matrix, and Array values in a `CREATE TABLE` statement require an alternate syntax than the examples shown in this table.
>
> For examples of how to specify these default values, see **Create a Table with All Data Types**.

| Name | Description | System Limits | Example Value |
|---|---|---|---|
| ARRAY | An array of the specified type in the format `TYPE[]`. The `TYPE` type can be any supported data type besides ARRAY. For example, `INT[]` creates an array of integers. | Maximum memory allocation: 512MiB | `INT[]\(1,2,3)` `[]\()` can be used for empty arrays. For example: `BIGINT[]\()` |
| BIGINT | 8-byte signed integer | Minimum value: `-9223372036854775808` | `9876543210` |

| Name | Description | System Limits | Example Value |
| --- | --- | --- | --- |
| | | Maximum value: `9223372036854775807` | |
| BINARY(N) or HASH(N) | Fixed-length binary array with length N | Maximum memory allocation: 512MiB<br><br>For HASH(N), the maximum value is N repeats of `0xFF`, and the minimum value is N repeats of `0x00`. | BINARY(4): `'0x01234567'`, BINARY(3): `'0xabcdef'` |
| BOOLEAN | 1-byte logical Boolean value | None | `TRUE`, `FALSE` |
| CHARACTER(N) or CHAR(N) or CHAR or CHARACTER | Variable-length character string. Length N is only for compatibility. The Ocient System does not use this argument. | Maximum memory allocation: 512MiB | CHAR(16): `'This is a string'` |
| DATE | 4-byte calendar date (year, month, day) | Minimum value: `0001-01-01`<br><br>Maximum value: `9999-12-31` | `'2020-02-02'`, `'2000-01-01'` |
| DECIMAL(P,S) | Exact numerical with precision P and scale S | Minimum value: `-99999999999999999999999999999999999999`<br><br>Maximum value: `99999999999999999999999999999999999999` | `123.45` |
| DOUBLE | 8-byte IEEE® double precision floating-point number | Minimum value: -1.7977 x 10^308<br><br>Maximum value: 1.7977 x 10^308 | `3.141592` |
| FUNCTION | Lambda function or user-defined function | None | `(x int, y int) -> CASE WHEN x = y THEN 0 WHEN INT(COALESCE(x, 1000)) < INT(COALESCE(y, 1000)) THEN -1 ELSE 1 END` |
| INT | 4-byte signed integer | Minimum value: `-2147483648` | `123456789` |

| Name | Description | System Limits | Example Value |
|---|---|---|---|
| | | Maximum value: `2147483647` | |
| IPV4 | 4-byte Internet Protocol version 4 | Minimum value: `0.0.0.0`<br><br>Maximum value: `255.255.255.255` | `'127.0.0.1'` |
| IP | 16-byte Internet Protocol version 6 (can also hold IPV4) | Minimum value: `0000:0000:0000:0000:0000:0000:0000:0000`<br><br>Maximum value: `ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff` | `'0123:4567:89ab:cdef:0123:4567:89ab:cdef'`, `'1111::0'`, `'127.0.0.1'` |
| LINESTRING | Geometric type composed of N points | Maximum memory allocation: 512MiB | `'LINESTRING(0 0,2 0)'` |
| MATRIX | A one- or two-dimensional mathematical matrix used for matrix calculations. | Minimum value: None<br><br>Maximum value: 67,108,864 elements<br><br>Maximum memory allocation: 512MiB | A Matrix[2][2]: `{ {0, 0}, {0, 0} }`<br>A Matrix [2][4]: `{ {0, 0, 0, 0}, {0, 0, 0, 0} }` |
| POINT | Geometric point in 2 dimensions | None | `'POINT(-87.6410 41.8841)'` |
| POLYGON | Geometric type composed of N closed linestrings | Maximum memory allocation: 512MiB | `'POLYGON((0 0,2 0,5 5,0 2,0 0), (0 0,1 0,2 2,0 2,0 0))'` |
| FLOAT | 4-byte IEEE single precision floating-point number | Minimum value: -3.4028 x 10^38<br><br>Maximum value: 3.4028 x 10^38 | `2.718` |
| SMALLINT | 2-byte signed integer | Minimum value: `-32768`<br><br>Maximum value: `32767` | `32767` |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Name | Description | System Limits | Example Value |
|---|---|---|---|
| TIME | 8-byte time of day in nanoseconds | Minimum value: `00:00:00.000000000`<br><br>Maximum value: `23:59:59.999999999` | `'12:34:56.012345678'` |
| TIMESTAMP | 8-byte date and time in nanoseconds with no associated time zone. | Minimum value: `1677-09-21 00:12:43.145224192`<br><br>Maximum value: `2262-04-11 23:47:16.854775807` | `'2000-01-02 12:34:45'` |
| TINYINT or BYTE | 1-byte signed integer | Minimum value: `-128`<br><br>Maximum value: `127` | `127` |
| TUPLE<<type1, type2, ...>> | Tuple of elements of different types. | Maximum memory allocation: 512MiB | `tuple<<INT,INT>>(1,2)`<br>An Array of Tuples: `tuple<<INT,INT>>[] (tuple<<INT,INT>>(1,2), tuple<<INT,INT>>(3,4))` |
| UUID | 16-byte universally unique identifier | Minimum value: `00000000-0000-0000-0000-000000000000`<br><br>Maximum value: `ffffffff-ffff-ffff-ffff-ffffffffffff` | `'01234567-89ab-cdef-1357-0123456789ab'` |
| VARBINARY(N) | Variable-length binary array with maximum length of N | Maximum memory allocation: 512MiB | VARBINARY(6): `'0xaabbccddeeff'` |
| VARCHAR(N) | Variable-length character string with maximum length of N | Maximum memory allocation: 512MiB | VARCHAR(4): `'This is a variable length string'` |

# Data Types for SQL Statements

DDL, DCL, and General SQL Syntax statements define parameter data types as either numeric or string. These data types are simplified terms that follow these rules:

- `numeric` — Any numeric value. This value defaults to the `BIGINT` data type if it is an integer with no decimal parts. If the number includes decimal parts, it defaults to

`DOUBLE`.

- `string` — A series of one or more characters. This value defaults to the `VARCHAR` data type.

## Data Type Considerations

Integer literals in SQL statements are of type BIGINT unless you explicitly cast them to another type. You can express integer literals in these formats:

- Decimal (default) — `42`, `1000000`
- Hexadecimal — `0x2A`, `0XFF`, `0Xab`, `0xcD` (case-insensitive)
- Octal — `0o52`, `00755` (case-insensitive)
- Binary — `0b101010`, `0B1100` (case-insensitive)

You can use underscore digit separators in any numeric literal for readability. The parser ignores underscores during evaluation. For example: `1_000_000`, `0xFF_FF`, `0b1010_0101`. An underscore cannot be the first character of a literal (e.g., `_42` is invalid).

Floating point literals in SQL statements are of type DOUBLE unless explicitly cast to another type.

TRUE and FALSE can be used in SQL statements as valid BOOLEAN literals.

Floating point values must be strictly numeric. Infinity and NaN values are unsupported.

The decimal type supports a maximum precision of 31 and a scale of one less than the precision.

Interval types can only be used within an expression. If the final result of an outermost expression is an interval type, the Ocient System automatically converts it to a BIGINT and the value loses the units information.

- “yyyy” : The year as a four-digit number.
- “MM” : The month, from 01 through 12.
- “dd” : The day of the month, from 01 through 31.
- “HH” : The hour, using a 24-hour clock from 00 to 23.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- “mm” : The minute, from 00 through 59.
- “ss” : The second, from 00 through 59.
- “FFFFFFFFF” : If non-zero, the billionths of a second in a date and time value.

## Data Type Compatibility

The Ocient System casts data types to the highest common type when possible in expressions to produce an output of that type. These data-type promotions occur in these hierarchies. This promotion often applies to `COALESCE`, `CONCAT`, and `||`, and other operators.

### Numeric Types

SQL

```
DOUBLE
FLOAT
DECIMAL
BIGINT
INT
SMALLINT
TINYINT
```

### Geospatial Types

SQL

```
POLYGON
LINESTRING
POINT
```

Geospatial functions might have semantic differences when you execute these functions with different types that have higher precedence than the type promotion of its arguments.

## Size Limits

Variable-length columns have limits to how large the value can be.

Data types with a 124 KiB size limit:

- TUPLE<<type1, type2, ...>> : Tuple value with a VARCHAR(N) or VARBINARY(N) type

Data types with a 512 MiB size limit:

- TYPE[]: The inner values of the array are subject to the size limits of the inner type.
- LINESTRING
- POLYGON
- VARBINARY(N)
- VARCHAR(N)

> The database ignores length of N for CHAR, VARCHAR, and VARBINARY. The database uses N for SQL conformance only.

> When you query data, if the database must analyze a value that exceeds 124 KiB at query execution time, the system increases memory usage. Large computed values are non-freeable during query execution, and the system cannot offload to temporary disk. Queries that operate on computed large values with many rows can cause the system to run out of memory and result in the killing of the query.

## Array

Array is a SQL type container that stores multiple elements of the same SQL type. Arrays can have zero or any number of values. For instance, an INT array can contain many integers, including NULL. Arrays in Ocient can store any SQL type: IPV4, IP, BOOLEAN, BYTE, SHORT, INT, LONG, FLOAT, DOUBLE, TIME, TIMESTAMP, CHAR, DATE, BINARY, HASH, POINT, UUID, DECIMAL, and TUPLE.

Arrays have special functions and operators that are described in the following sections:

- **Array Functions**
- **Array Operators**

## Tuple

Tuple is a SQL type container that is meant to store elements of different types. Ocient supports tuples using any of the supported SQL types: IPV4, IP, BOOLEAN, BYTE, SHORT,

INT, BIGINT, FLOAT, DOUBLE, TIME, TIMESTAMP, CHAR, DATE, BINARY, HASH, POINT, UUID, and DECIMAL. In Ocient, tuples can either exist as single columns, SQL array elements, nested tuples, or tuples of arrays.

Tuple functions and operators are described in the following sections:

- **Tuple Functions**
- **Tuple Operators**

## Matrix

Matrix is a SQL-type container. It is a fixed-size, one or two-dimensional array (mathematical matrix) of the same fixed-size SQL data types. Currently, Matrix only supports storing doubles. Matrix dimensions must be non-zero.

Matrix functions and operators are described in the following sections:

- **Matrix Functions**
- **Matrix Operators**

## Geospatial Data Types

Ocient supports three different geospatial geographies: POLYGONS, LINESTRINGS, and POINTS.

- A `POLYGON` can be constructed with a closed LINESTRING or an outer shell and an array of inner rings.
- A `LINESTRING` represents a series of POINTS connected by line segments. It can be constructed with either LINESTRINGS or POINTS.
- A `POINT` represents a point in space defined by an (x, y)/(long, lat) coordinate pair.

Polygon semantics in the Ocient System follow the **OGC standard (ISO 19125-1) for LinearRings**, where the exterior and holes can be meaningfully oriented either counter-clockwise or clockwise. To conceptualize this, imagine walking along the exterior of the polygon in the order of its defined points, so everything to your left is the “interior” of the polygon. A counter-clockwise polygon is the typical orientation where, using an example of a state boundary, the interior of the state corresponds to the interior of the polygon. If

you define the state boundary using the clockwise orientation, the interior of the polygon represents everything except the state.

> If a counter-clockwise exterior polygon has holes, the holes should be clockwise-oriented.

> Ensure that both the data and polygon literals are oriented in the way you intend when you use them in queries.

## Geography Equivalent

Many other geospatial implementations use an object-oriented approach to geospatial data types by implementing a `GEOGRAPHY` union type that might contain any combination of these types: `POINT`, `LINESTRING`, or `POLYGON`.

Ocient supports `GEOGRAPHY` slightly differently by using `POLYGON` as an implicit union type. This container type means unclosed `POLYGON` types with no holes are equivalent to `LINESTRING` types, and that a `POLYGON` might contain a single `POINT`. This definition of a `POLYGON` differs from other implementations, where such `POLYGON` types would be considered degenerate. During loading, Ocient is able to convert incoming `GEOGRAPHY` data to the appropriate `POLYGON` equivalent. Ocient geospatial functions appropriately handle these cases as needed.

## Spatial Reference Identifier (SRID)

Similar to geography union types, many other geospatial implementations define an attribute table of column identifiers and an associated SRID. The system uses the SRID lookup to define semantics of functions such as `st_area`, which uses different calculations if the specified polygon is planar, defined on an ideal sphere, or on a spheroid. The identifiers also specify units of measure and the number of variables used to define a point in the reference system. However, Ocient only supports the storage of latitude and longitude coordinates for its geography types, and uses only GCS WGS 84 (EPSG code 4326) semantics. Rather than applying a transformation like you might in other implementations to change units or model accuracy, the geospatial measurement functions in the Ocient System allow you to specify the units of measure directly, as well as whether to use a faster idealized sphere model of the Earth, or a more accurate spheroidal model.

© 2026 Ocient, Inc

Ensure that you set the units and spheroidal model correctly when performing critical measurements. Also, be careful when you export data from other databases to Ocient so that the incoming data is in GCS WGS 84 format. Ensure that you use the Loading and Transformation pipeline to prepend or strip SRID definitions from EWKT or EWKB-formatted data. Internally, the Ocient System has no concept of SRIDs, however it does support parsing and emitting SRID-prepended data for compatibility with external tools. When the database parses SRID-prepended data, the system ignores the SRID component and parses the data as a GCS WGS 84 defined geography.

### Geospatial Functions

Each geospatial geography has a number of functions and operators that can be used in SQL queries to perform analyses. Some functions apply to specific geography types. For more function and operator specifics, see **Geospatial Functions**.

# Date and Time Functions

Reference for Ocient SQL date and time functions, including timestamp arithmetic, formatting, parsing, time zone conversion, and date part extraction.

## Basic Date and Time Functions

### ADD_MONTHS

Adds the specified number of months to the date. Equivalent to using a date and adding a `MONTH(value)`.

#### Syntax

```
SQL

ADD_MONTHS(time, int)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function modifies by adding a specified number of months. |
| `int` | `INT` | The number of months to add to the `time` value. |

#### Example

```
SQL

SELECT ADD_MONTHS('2022-11-15 04:18:00',2);
```

*Output*: `2023-01-15`

### CENTURY

Returns the number of centuries.

### Syntax

```
SQL

CENTURY(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes to return the number of its centuries. |

### Example

In this example, the current date is `2023-01-03`.

```
SQL

SELECT CENTURY(CURRENT_DATE());
```

*Output*: `21`

## CURDATE

Alias for CURRENT_DATE.

## CURRENT_DATE

Alias for CURDATE.

Returns the current date in the format `YYYY-MM-DD`.

### Syntax

```
SQL

CURRENT_DATE
```

### Example

```sql
SELECT CURRENT_DATE;
```

*Output*: `2023-01-03`

## CURRENT_TIME

Returns the current time as a TIME value (e.g., `hh:mm:ss.mm`).

### Syntax

```sql
CURRENT_TIME
```

### Example

```sql
SELECT CURRENT_TIME;
```

*Output:* `19:40:04`

## CURRENT_TIMESTAMP

Alias for **NOW**.

Returns the current date and time as a TIMESTAMP value (e.g., `YYYY-MM-DD hh:mm:ss.mmm`).

### Syntax

```sql
CURRENT_TIMESTAMP
```

### Example

```sql
SELECT CURRENT_TIMESTAMP;
```

*Output*: `2023-01-03 11:00:03.316674397`

## DATE_PART

Alias for **EXTRACT**.

## DATE_TRUNC

Returns the date or timestamp entered, truncated to the specified precision.

### Syntax

```sql
DATE_TRUNC(precision, time)
```

| Argument | Data Type | Description |
|---|---|---|
| `precision` | `CHAR` | The timestamp unit used to truncate the returned value. For the `precision` input, acceptable values are: `NANOSECOND` `MICROSECOND` `MILLISECOND` `SECOND` `MINUTE` `HOUR` `DAY` `WEEK` `MONTH` `QUARTER` `YEAR` `DECADE` `CENTURY` `MILLENNIUM` |
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function truncates to the specified precision. The `time` input supports precision values DAY or larger. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-01-03 11:00:59.114058182`.

```
SQL
SELECT DATE_TRUNC('NANOSECOND', CURRENT_TIMESTAMP());
```

*Output*: `2023-01-03 11:01:05.280975906`

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-01-01 11:00:59.114058181`.

```
SQL
SELECT DATE_TRUNC('MONTH', CURRENT_TIMESTAMP());
```

*Output*: `2023-01-01 00:00:00.000000000`

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-01-01 11:00:59.114058181`.

```
SQL
SELECT DATE_TRUNC('CENTURY', CURRENT_TIMESTAMP());
```

*Output*: `2001-01-01 00:00:00.000000000`

## DAY

Alias for **DAY_OF_MONTH**.

## DAY_OF_WEEK

Returns an integer, in the range of 1 to 7, that represents the day of the week. The value 1 is Sunday, and 7 is Saturday.

### Syntax

```sql
DAY_OF_WEEK(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes for its day of the week. |

### Example

```sql
SELECT DAY_OF_WEEK(CURRENT_DATE());
```

*Output*: `3`

## DAY_OF_YEAR

Alias for DOY.

Returns an integer in the range 1 to 366 that represents the day of the year.

### Syntax

```sql
DAY_OF_YEAR(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes for its day of year. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-01-03 11:00:59.114058182`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

```sql
SELECT DAY_OF_YEAR(CURRENT_TIMESTAMP());
```

*Output*: `3`

## DAY_OF_MONTH

Alias for DAY.

Extracts the day-of-month portion of a timestamp or date as an integer.

### Syntax

```sql
DAY_OF_MONTH(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes for its day of the month. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-01-03 11:00:59.114058182`.

```sql
SELECT DAY(CURRENT_TIMESTAMP());
```

*Output*: `3`

## DECADE

The decade is the year divided by 10.

### Syntax

```sql
DECADE(time)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes for its decade. |

### Example

This example uses `CURRENT_DATE` set to `2023-01-03`.

```sql
SELECT DECADE(CURRENT_DATE());
```

*Output*: `202`

## DOW

Alias for **DAY_OF_WEEK**.

## DOY

Alias for **DAY_OF_YEAR**.

## EOMONTH

Returns the last day of the month using the specified timestamp or date. If you specify both arguments, this function returns the last day of the month for the resulting timestamp or date after the system adds the specified number of months to the first argument value.

### Syntax

```sql
EOMONTH(time [, int])
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Argument | Data Type | Description |
| --- | --- | --- |
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes for the last day of the month. |
| `int` | `INT` | Optional. An integer value that represents the number of months to add to the `time` value.<br>If unspecified, the value defaults to 0. |

### Examples

This example returns the last day of the month for the current timestamp.

```
SQL
SELECT EOMONTH(CURRENT_TIMESTAMP(),0);
```

*Output*: `2023-02-27`

This example returns the last day of the month in November in 2022 by using the EOMONTH function to add one month to the last day of October in 2022.

```
SQL
SELECT EOMONTH(DATE('2022-10-31'), 1);
```

*Output*: `2022-11-30`

## EPOCH

The number of seconds after 1970-01-01 00:00:00 UTC.

### Syntax

```
SQL
EPOCH(time)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes for the number of seconds after 1970-01-01 00:00:00 UTC. |

### Example

```
SQL

SELECT EPOCH(CURRENT_TIMESTAMP());
```

*Output*: `1672743901`

## EXTRACT

Extract a component from a timestamp or date.

### Syntax

```
SQL

EXTRACT(precision FROM time)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes for the component to be extracted. |
| `precision` | `CHAR` | The timestamp unit to be extracted.<br>For the `precision` input, acceptable values are:<br>`NANOSECOND`<br>`MICROSECOND`<br>`MILLISECOND`<br>`SECOND`<br>`MINUTE`<br>`HOUR`<br>`DAY`<br>`WEEK`<br>`MONTH`<br>`QUARTER`<br>`YEAR`<br>`DECADE` |

| Argument | Data Type | Description |
| --- | --- | --- |
| | | `CENTURY`<br>`MILLENNIUM` |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-01-03 11:00:59.114058182`.

SQL

```
SELECT EXTRACT(HOUR FROM CURRENT_TIMESTAMP());
```

*Output*: `11.0`

## HOUR

Extracts the hour portion of a timestamp as an integer.

### Syntax

SQL

```
HOUR(time)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes for its hour value. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-01-03 11:00:59.114058182`.

SQL

```
SELECT HOUR(CURRENT_TIMESTAMP());
```

*Output*: `11`

## ISODOW

Extracts the day of the week based on ISO 8601, which ranges from Monday (1) to Sunday (7).

### Syntax

```sql
ISODOW(timestamp or date)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes for its day-of-week value. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-01-03 11:00:59.114058182`.

```sql
SELECT ISODOW(CURRENT_TIMESTAMP());
```

*Output*: `2`

## ISDATE

Returns `TRUE` if the input argument can be successfully cast to a date, `FALSE` otherwise.

### Syntax

```sql
ISDATE(char)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `char` | `CHAR` | A string to cast as a `DATE`. |

### Example

SQL

```
SELECT ISDATE('2023-01-03');
```

*Output*: `TRUE`

## MAKEDATETIME

Returns a timestamp consisting of the specified date and time.

### Syntax

SQL

```
MAKEDATETIME(date, time)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `date` | `CHAR` | A date string for timestamp creation. |
| `time` | `CHAR` | A time string for timestamp creation. |

### Example

SQL

```
SELECT MAKEDATETIME('2022-11-02','01:24:58');
```

*Output*: `2022-11-02 01:24:58.000000000`

## MILLISECOND

Extracts the millisecond portion of a timestamp as an integer.

### Syntax

```
SQL

MILLISECOND(timestring)
```

| Argument | Data Type | Description |
|---|---|---|
| `timestring` | `TIMESTAMP` | A time value, specified as a timestamp or date, which the function extracts for the millisecond value. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-02-22 13:59:25.286`.

```
SQL

SELECT MILLISECOND(CURRENT_TIMESTAMP());
```

*Output*: `286`

## MINUTE

Extracts the minute portion of a timestamp or date as an integer.

### Syntax

```
SQL

MINUTE(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function extracts for the minute value. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-02-22 14:00:40.764`.

```sql
SELECT MINUTE(CURRENT_TIMESTAMP());
```

*Output*: `0`

## MONTH_NAME

Returns the calendar name in English of the month for the specified date.

Syntax

```sql
MONTH_NAME(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes its month name. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-02-22 13:59:25.286`.

```sql
SELECT MONTH_NAME(CURRENT_TIMESTAMP());
```

*Output*: `February`

## MONTHS_BETWEEN

Returns the difference between the two dates or timestamps in months as a `DOUBLE`. The fractional months component is based on a 31-day month. If the two dates have the same day or are both the last day of the month, this function returns a whole number instead.

### Syntax

```
SQL

MONTHS_BETWEEN(time1, time2)
```

| Argument | Data Type | Description |
|---|---|---|
| `time1` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function compares to `time2` for the difference in months. |
| `time2` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function compares to `time1` for the difference in months. |

### Example

```
SQL

SELECT MONTHS_BETWEEN(CURRENT_TIMESTAMP(), ADD_MONTHS(CURRENT_TIMESTAMP(),11));
```

*Output*: `-11`

## MONTH

Extracts the month portion of a timestamp or date as an integer.

### Syntax

```
SQL

MONTH(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes for its month value. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-02-22 13:59:25.286`.

```sql
SELECT MONTH(CURRENT_TIMESTAMP());
```

*Output*: `2`

## MSECS

The seconds field, including fractional parts. This is the same as `EXTRACT(MILLISECONDS FROM time)`.

### Syntax

```sql
MSECS(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date. The function multiplies the seconds part of the value by 1,000. |

### Example

```sql
SELECT MSECS(CURRENT_TIMESTAMP());
```

*Output*: `37637.648`

## NANOS_TO_TIMESTAMP

Convert a number of nanoseconds into a timestamp equivalent to the duration after the epoch time, 1970-01-01 00:00:00 UTC.

### Syntax

```sql
NANOS_TO_TIMESTAMP(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `ns` | `INT` | A number of nanoseconds, specified as an integer, which the function converts into a timestamp equivalent to the duration after the epoch time. |

### Example

```sql
SELECT NANOS_TO_TIMESTAMP(10000000);
```

*Output*: `1969-12-31 16:00:00.010`

## NEXT_DAY

Returns the closest date after a specified date that lies on a specific day of the week.

### Syntax

```sql
NEXT_DAY(date, character)
```

| Argument | Data Type | Description |
|---|---|---|
| `date` | `DATE`, `TIMESTAMP`, or `CHAR` | A time value, specified as a date, timestamp, or string, which the function uses to return the closest date for a specific day of the week. Can be any type that can be cast to `DATE`. |
| `character` | `CHAR` | A string representing a day of the week.<br>The string must match the first three characters (case insensitive) of the English name of any day of the week. If this string does not match the prefix of any day, this function returns NULL. |

### Example

```sql
SELECT NEXT_DAY('2023-02-27', 'sat');
```

*Output*: `2023-03-04`

## NOW

Alias for **CURRENT_TIMESTAMP**.

## QUARTER

Returns an integer between 1 and 4 representing the quarter of the year in which the specified date falls.

### Syntax

```sql
QUARTER(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function computes to return the quarter of the year. |

### Example

```sql
SELECT QUARTER(DATE('2023-02-08 09:00:00.000'));
```

*Output*: `1`

## ROUND

Returns the specified date or timestamp, rounded to the specified precision. The precision argument behaves like **DATE_TRUNC**. The function rounds up values to the specified precision.

### Syntax

```SQL
ROUND(time, precision)
```

| Argument | Data Type | Description |
|---|---|---|
| `precision` | `CHAR` | The timestamp unit used to round the returned value. For the `precision` input, acceptable values are: `NANOSECOND` `MICROSECOND` `MILLISECOND` `SECOND` `MINUTE` `HOUR` `DAY` `WEEK` `MONTH` `QUARTER` `YEAR` `DECADE` `CENTURY` `MILLENNIUM` |
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function rounds to the specified precision. |

### Example

```SQL
SELECT ROUND(CURRENT_TIMESTAMP() ,'HOUR');
```

*Output*: `2023-02-08 09:00:00.000`

## SECOND

Extracts the seconds portion of a timestamp as an integer.

### Syntax

```sql
SECOND(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `TIME` | A time value, specified as a timestamp or date, which the function uses to return the seconds value. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-02-28 13:17:30.243`.

```sql
SELECT SECOND(CURRENT_TIMESTAMP());
```

*Output*: `30`

## TIMESTAMP_TO_NANOS

Convert timestamp into nanoseconds after epoch as `BIGINT`.

### Syntax

```sql
TIMESTAMP_TO_NANOS(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function uses to return the nanoseconds after the epoch. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-02-28 13:20:12.373`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

```sql
SELECT TIMESTAMP_TO_NANOS(CURRENT_TIMESTAMP());
```

*Output*: `1677619212373708904`

## TO_TIMESTAMP

For information on using the TO_TIMESTAMP conversion function, see the **TO_TIMESTAMP** page.

## USECS

Returns the seconds part of a time value, including fractional parts, as an integer. Same as `EXTRACT(MICROSECONDS FROM time)`.

### Syntax

```sql
USECS(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date. The function multiplies the seconds part of the value by 1,000,000. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-02-28 13:32:17.438`.

```sql
SELECT USECS(CURRENT_TIMESTAMP());
```

*Output*: `17438041`

## WEEK

Returns the ISO-8601 week number, as an integer, of the specified timestamp or date value. The week starts on Monday, and the first week of a year contains January 4 of that year.

For details, see the **ISO week date** definition.

### Syntax

```
SQL

WEEK(time)
```

| Argument | Data Type | Description |
|---|---|---|
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function uses to return the week number. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-02-28 13:37:37.128`.

```
SQL

SELECT WEEK(CURRENT_TIMESTAMP());
```

*Output*: `9`

## YEAR

Extracts the year portion of a timestamp or date as an integer.

### Syntax

```
SQL

YEAR(time)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `time` | `TIMESTAMP` or `DATE` | A time value, specified as a timestamp or date, which the function uses to extract the year. |

### Example

This example uses `CURRENT_TIMESTAMP` set to `2023-02-28 13:37:37.128`.

SQL

```
SELECT YEAR(CURRENT_TIMESTAMP());
```

*Output*: `2023`

# Advanced Date and Time Functions

## DATEADD

This function adds a specified number value (as a signed integer) to a specified `datepart` of an input date value, and then returns that modified value.

The data type of the returned value for this function is dynamic. The return type depends on the argument supplied for `date`. If the value for `date` is a string literal `date`, `DATEADD` returns a `datetime` value. If another valid input data type is supplied for `date`, `DATEADD` returns the same data type. `DATEADD` raises an error if the string literal seconds scale exceeds three decimal place positions (.nnn) or if the string literal contains the time zone offset part.

### Syntax

SQL

```
DATEADD(datepart, number, date)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `datepart` | `CHAR` | The part of the date to which DATEADD adds an integer number. |

| Argument | Data Type | Description |
|---|---|---|
| | | See the Datepart Values table for a list of supported arguments. |
| `number` | `INT` | An expression that can resolve to an `INT` that `DATEADD` adds to the specified `datepart` value of `date`.<br>`DATEADD` accepts user-defined variable values for number.<br>`DATEADD` truncates a specified `number` value that has a decimal fraction. In this situation, it does not round the number value. |
| `date` | `TIME`, `TIMESTAMP`, `DATE` | A column expression, expression, string literal, or user-defined variable. A string literal value must resolve to a date or timestamp.<br>Use four-digit years to avoid ambiguity issues. |

| *datepart* | Abbreviations |
|---|---|
| `year` | yy, yyyy |
| `quarter` | qq, q |
| `month` | mm, m |
| `dayofyear` | dy, y |
| `day` | dd, d |
| `week` | wk, ww |
| `weekday` | dw, w |
| `hour` | hh |
| `minute` | mi, n |
| `second` | ss, s |
| `millisecond` | ms |
| `microsecond` | mcs |
| `nanosecond` | ns |

`DATEADD` does not accept user-defined variable equivalents for the `datepart` arguments.

## Examples

This example shows each result from incrementing different `datepart` values by 1.

SQL

```
SELECT 'year', DATEADD(year,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'quarter', DATEADD(quarter,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'month', DATEADD(month,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'dayofyear', DATEADD(dayofyear,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'day', DATEADD(day,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'week', DATEADD(week,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'weekday', DATEADD(weekday,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'hour', DATEADD(hour,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'minute', DATEADD(minute,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'second', DATEADD(second,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'millisecond', DATEADD(millisecond,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'microsecond', DATEADD(microsecond,1, '2007-01-01 13:10:10.1111111')
    UNION ALL
SELECT 'nanosecond', DATEADD(nanosecond,1, '2007-01-01 13:10:10.1111111');
```

*Output*

## DATEDIFF

This function returns an `INT` representing the difference between two date or time values, in a specified date or time unit.

If only a time value is assigned to a date data type variable, `DATEDIFF` sets the value of the missing `datepart` to the default value: `1900-01-01`. If only a date value is assigned to a variable of a time or date data type, `DATEDIFF` sets the value of the missing time part to the default value: `00:00:00`. If either `startdate` or `enddate` have only a time part and the other only a `datepart`, `DATEDIFF` sets the missing time and `datepart` to the default values.

If `startdate` and `enddate` have different date data types, and one has more time parts or fractional seconds precision than the other, `DATEDIFF` sets the missing parts of the other to 0.

### Syntax

SQL

```
DATEDIFF(datepart, startdate, enddate)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `datepart` | `CHAR` | The units in which the function returns the difference between the `startdate` and `enddate`. Commonly used `datepart` units include `month` or `second`.<br>The `datepart` value cannot be specified in a variable, or in a quoted string like `'month'`.<br>If `datepart` has a DATE value, and `startdate` and `enddate` are both assigned a TIME value, then the function returns `0`.<br>See the Datepart Values table for a list of supported arguments. |
| `startdate` | `TIME`, `TIMESTAMP`, `DATE` | A starting date or time value to determine the difference from the `enddate` value.<br>If only a time value is assigned, `DATEDIFF` sets the value of the missing `datepart` to the default value: `1900-01-01` |
| `enddate` | `TIME`, `TIMESTAMP`, `DATE` | An ending date or time value to determine the difference from the `startdate` value.<br>If only a time value is assigned, `DATEDIFF` sets the value of the missing `datepart` to the default value: `1900-01-01` |

| *datepart* | Abbreviations |
| --- | --- |
| `year` | yy, yyyy |
| `quarter` | qq, q |
| `month` | mm, m |
| `dayofyear` | dy, y |
| `day` | dd, d |
| `week` | wk, ww |
| `weekday` | dw, w |
| `hour` | hh |
| `minute` | mi, n |
| `second` | ss, s |
| `millisecond` | ms |
| `microsecond` | mcs |
| `nanosecond` | ns |

For `millisecond`, the maximum difference between `startdate` and `enddate` is 24 days, 20 hours, 31 minutes, and 23.647 seconds.

For `second`, the maximum difference is 68 years, 19 days, 3 hours, 14 minutes, and 7 seconds.

Each specific `datepart` name and abbreviations for that `datepart` name return the same value.

## Example

The example shows how `DATEDIFF` calculates the difference between the two values based on the various `datepart` values.

# Formatting Functions

Reference for Ocient SQL formatting functions to convert values between text and other types using format strings, locales, padding, and precision options.

## Formatting Considerations

- The format string can be any combination of characters and format patterns for each function specified in the **Date and Timestamp Formatting Patterns** and **Date and Timestamp Formatting Modifiers** tables.
- Patterns can be uppercase or lowercase, but not mixed case. YYYY or yyyy matches YYYY, but not YyYy.
- Any characters in the format string that are not part of a pattern match any character in that position in TO_DATE, TO_NUMBER, and TO_TIMESTAMP.
- You can escape string literals that contain format patterns with quotes. For example: `YYYY"a literal part YYYY"`

## Date and Time Formatting Functions

### Date and Timestamp Formatting Patterns

| Pattern | Description |
|---|---|
| Y,YYY | 4 digit year with comma |
| YYYY | 4 digit year |
| YYY | Last 3 digits of a year. Values between 000-599 are assumed to be the year 2XXX and 600-999 are assumed to be the year 1XXX. |
| YY | Last 2 digits of a year. Values between 00-69 are assumed to be the year 20XX and 70-99 are assumed to be 19XX. |
| Y | Last digit of a year. Assumed to be year 200X. |
| BC, bc, AD, or ad | An era indicator BC or AD in upper or lower case |
| B.C., b.c., A.D., or a.d. | An era indicator B.C. or A.D. in upper or lower case |
| CC | Century value 1-99. Is ignored unless YY, Y, IY, or I are set |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Pattern | Description |
|---|---|
| MM | Month of the year value 01-12 |
| MONTH | Upper case English month name |
| Month | English Month name with first letter capitalized |
| month | lower case English month name |
| RM | Upper case month of year in Roman numerals |
| rm | Lower case month of year in Roman numerals |
| MON | 3 letter upper case abbreviation of an English month name |
| Mon | 3 letter abbreviation of an English month name with first letter capitalized |
| mon | 3 letter lower case abbreviation of an English month name |
| W | Week of month 1-5. For example: Days 15-21 are in the third week of the month. |
| DD | Day of month 1-31 |
| WW | Week of year 1-53 |
| DDD | Day of year 1-366 |
| D | Day of week 1-7 where Sunday is 1. This value is ignored outside of to_char. |
| IYYY | 4 digit ISO-8601 week-numbered year. See **ISO week date** for more details. |
| IYY | Last 3 digits of an ISO-8601 week-numbered year. Values between 000-599 are assumed to be the year 2XXX and 600-999 are assumed to be the year 1XXX. |
| IY | Last 2 digits of an ISO-8601 week-numbered year. Values between 00-69 are assumed to be the year 20XX and 70-99 are assumed to be 19XX. |
| I | Last digit of an ISO-8601 week-numbered year. Assumed to be the year 200X. |
| IDDD | Day of an ISO-8601 week-numbered year 001-371 |
| IW | Week of an ISO-8601 week-numbered year 01-53 |
| ID | Day of an ISO-8601 week 01-07 where Monday is 1 |
| HH or HH12 | Hour of day 01-12 |
| HH24 | Hour of day 0-23 |
| AM, am, PM, or pm | Meridiem indicator AM or PM in upper or lower case |
| A.M., a.m., P.M., or p.m. | Meridiem indicator A.M. or P.M. in upper or lower case |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Pattern | Description |
|---|---|
| SSSS | Seconds after midnight 0-86399 |
| MI | Minute of hour 0-59 |
| SS | Second of minute 0-59 |
| MS | Milliseconds 000-999 |
| US | Microseconds 000000-999999 |
| NS | Nanoseconds 000000000-999999999 |
| J | Julian Day (days after November 24, 4714 BC at midnight) |

The following modifiers can also be applied to a format pattern.

## Date and Timestamp Formatting Modifiers

| Modifier | Description |
|---|---|
| FM | Has no effect on TO_DATE and TO_TIMESTAMP. Will not be considered a literal, but will not otherwise affect the behavior. |
| TH | Upper case ordinal number suffix. For example: `'DDTH'` |
| th | Lower case ordinal number suffix. For example: `'DDth'` |
| FX | Global prefix. By default, TO_DATE and TO_TIMESTAMP collapse all spaces to a single space. If FX is specified, spaces are not collapses. FX must be at the beginning of the format string to be applied. For example: `'FX YYYY-MM-DD'` |
| TM | Has no effect on TO_DATE and TO_TIMESTAMP. Will not be considered a literal, but will not otherwise affect the behavior. |
| SP | Has no effect on TO_DATE and TO_TIMESTAMP. Will not be considered a literal, but will not otherwise affect the behavior. |

## Date and Time notes

- You can use time specifiers such as HH12 in `TO_DATE`. Their format will be validated, but their values will not affect the resulting date.
- ISO 8601 formats for dates cannot be mixed with traditional formats for years, months, and days in `TO_DATE` and `TO_TIMESTAMP`

- Values for MS, US, and NS are scaled up if they do not have leading zeros. `TO_TIMESTAMP('0.3', 'S.NS')` corresponds to 300000000 NS and `TO_TIMESTAMP('0.000000003', 'S.NS')` corresponds to 3 NS.
- Conflicting information for the same pattern will cause an exception. ex: `TO_DATE('05 31', 'DD DD')`
- Conflicting information across different patterns such as DD and DDD will generally give precedence to the pattern that appears higher in the table.

## TO_TIMESTAMP

Converts a character value with the specified format to a `TIMESTAMP` type.

### Syntax

```
SQL

TO_TIMESTAMP(character_value, character_format)
```

| Arguments | Data Type | Description |
|---|---|---|
| `character_value` | `CHAR` | A string of a value to be converted to a `TIMESTAMP` type. The string must match the provided `character_format`. |
| `character_format` | `CHAR` | The format pattern to be used to convert the `character_value`. See the **Date and Timestamp Formatting Patterns** section for more information about accepted pattern values. |

### Examples

```
SQL

SELECT TO_TIMESTAMP('2022/12/01', 'YYYY/MM/DD');
```

*Output*: `2022-12-01 00:00:00.000`

```
SQL

SELECT TO_TIMESTAMP('2023-02-28 13:43:20.403', 'YYYY/MM/DD HH24:MI:SS');
```

© 2026 Ocient, Inc

*Output*: `2023-02-28 13:43:20.000`

## TO_DATE

Converts a character value with the specified format to a `DATE` type.

### Syntax

```
SQL

TO_DATE(character_value, character_format)
```

| Arguments | Data Type | Description |
|---|---|---|
| `character_value` | `CHAR` | A string of a value to be converted to a `DATE` type. The string must match the provided `character_format`. |
| `character_format` | `CHAR` | The format pattern to be used to convert the `character_value`. See the **Date and Timestamp Formatting Patterns** section for more information about accepted pattern values. |

### Example

```
SQL

SELECT TO_DATE('2022/12/01', 'YYYY/MM/DD');
```

*Output*: `2022-12-01`

# Number Formatting Functions

## Number Formatting Patterns

| Pattern | Description |
|---|---|
| 9 | A digit. |
| 0 | A digit. In TO_CHAR, includes leading zeros. |
| . or D | A decimal point. |

| Pattern | Description |
| --- | --- |
| , or G | A group/thousand separator. |
| PR | Negative value in braces. For example: `-1 = <1>` |
| S or SG | A + or - sign for positive or negative, respectively. |
| MI | A - sign if the number is negative. |
| PL | A + sign if the number is positive. |
| V | Shifts the decimal place by the number of digits after V in the format. Cannot be mixed with `.` or `D`. For example: `TO_NUMBER('32', '9V99')` => 0.32 |
| RN | Roman numeral. Not supported by TO_NUMBER. |
| EEEE | Exponent for scientific notation. Not supported by TO_NUMBER. |
| L | Currency symbol. |

## Number Formatting Notes

- You cannot mix PR with other sign indicators.
- Any character that does not match the corresponding group in the format string is ignored. `TO_NUMBER('1&2', '999')` = 12.
- If PR is present, it must be after every 0 or 9 in the format string.
- Similar to TO_DATE and TO_TIMESTAMP, the FM is not considered a literal, but will not otherwise affect the behavior of TO_NUMBER.

## TO_NUMBER

Converts a character value with the specified format to a `DECIMAL` type.

### Syntax

SQL

```
TO_NUMBER(character_value, character_format)
```

| Arguments | Data Type | Description |
| --- | --- | --- |
| `character_value` | `CHAR` | A string of a value to be converted to a `DECIMAL` type. The string must match the provided `character_format`. |

| Arguments | Data Type | Description |
| --- | --- | --- |
| `character_format` | `CHAR` | The format pattern to be used to convert the `character_value`. See the **Number Formatting Patterns** section for more information about accepted pattern values. |

### Example

SQL

```
SELECT TO_NUMBER('5230.87', '9999V99');
```

*Output*: `5230.87`

# HyperLogLog Functions

Reference for HyperLogLog functions in Ocient SQL for fast, approximate distinct counting at scale, including merge and cardinality estimation operations.

The HyperLogLog (HLL) sketch family of functions provides an approximate count of the number of unique elements in one or more columns.

HLL functionality is similar to running a query using a `COUNT(DISTINCT col)` clause and uses the same mechanisms as the **aggregate function** `APPROX_COUNT_DISTINCT`.

The tradeoff for HLL sketches is accuracy. For further explanation of this tradeoff in accuracy, see the Apache® **DataSketches documentation**. Each sketch is an approximate and compact representation of the original data, and it introduces a small margin of error. The Ocient® HLL implementation is based on the algorithm outlined in the research paper **HyperLogLog in Practice**. This implementation uses `log2k = 11` by default, which provides a percent error of approximately 5% at the 95% confidence interval.

## HLL Sketch Functions in the SQL Statement

Sketches are useful on aggregated tables that require estimates of distinct counts.

This example creates a table for the new sketch columns `ip_address_sketch` and `user_id_sketch` as part of a CREATE TABLE AS SELECT statement. The new table inserts values from the `master_agg_table` table.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE TABLE my_sketch_table (
   col_a INT,
   col_b VARCHAR(255),
   ip_address_sketch HLL_SKETCH(11),
   user_id_sketch HLL_SKETCH(11)
 )
AS (
    SELECT
    col_a,
    col_b,
    HLL_SKETCH_CREATE(ip_address) as ip_address_sketch,
    HLL_SKETCH_CREATE(user_id) as user_id_sketch
FROM
    master_agg_table
    GROUP by 1,2);
```

After the database creates the new table, you can query for the approximate count of distinct values.

This example merges the sketch columns by using an `HLL_SKETCH_UNION` function. After the database merges the columns, the database converts sketch values to a distinct count estimate by using the `HLL_SKETCH_GET_ESTIMATE` function.

SQL

```
SELECT
    HLL_SKETCH_GET_ESTIMATE(HLL_SKETCH_UNION(ip_address_sketch)) AS ip_address_sket
    HLL_SKETCH_GET_ESTIMATE(HLL_SKETCH_UNION(user_id_sketch)) AS user_id_sketch
FROM
    my_sketch_table;
```

## HLL Accuracy with log2k Parameter

In addition to the default `log2k = 11` implementation, you can specify a `log2k` value in the range of [10, 16] when creating an HLL Sketch.

This parameter controls the number of buckets used in the HLL algorithm, which controls the accuracy of the sketch upper bounded by `1.04 / sqrt(k)`. The tradeoff with larger

`log2k` values is that the sketch size grows exponentially. See this table for specifics on how the precision values affect size and accuracy.

| Precision | Uncompressed Size | 95% CI |
|---|---|---|
| 10 | 1032 B | ±6.50% |
| 11 (default) | 2056 B | ±4.60% |
| 12 | 4104 B | ±3.25% |
| 13 | 8200 B | ±2.30% |
| 14 | 16392 B | ±1.63% |
| 15 | 32776 B | ±1.15% |
| 16 | 65544 B | ±0.81% |

By default, `log2k` values larger than 11 are compressed on disk using ZSTD compression.

> When creating or referencing a HLL Sketch column in a `CREATE TABLE`, `CTAS` or `IAS` statement, you can use the type alias `HLL_SKETCH(log2k)` instead of the internal `HASH((2^log2k) + 8)`.
>
> This type alias is supported in `EXPORT` statements as well.

### Example

In this example, a CREATE TABLE statement creates two HLL Sketch columns with specified `log2k` precision values.

- `sketch_a` has a precision value of `10`, meaning it has low precision and low storage requirements.
- `sketch_b` has a precision value of `15`, meaning it has high precision and high storage requirements.

Note that the precision values specified in both HLL_SKETCH_CREATE statements match the precision values in the CREATE TABLE columns.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE TABLE my_sketch_table (
    sketch_a HLL_SKETCH(10),
    sketch_b HLL_SKETCH(15)
 )
AS (
    SELECT
    HLL_SKETCH_CREATE(col_a, 10) as sketch_a,
    HLL_SKETCH_CREATE(col_b, 15) as sketch_b
FROM
    master_agg_table
    GROUP by 1,2);
```

# Supported HLL Sketch Functions

## HLL_SKETCH_CREATE

Creates an HLL sketch from the data on a specified aggregated column. Returns a `HASH((2^log2k) + 8)` data representation of the sketch that you can store in a separate column.

> The HLL algorithm depends on the hash value of its input. When merging multiple sketches, it is important that each sketch derives from the same type in order to get accurate results. `1::BIGINT` might hash differently than `1::INT`, and thus, the HLL algorithm might not view these two hashes as referring to the same value `1`.
>
> For accurate results, users should cast numeric columns or expressions to a consistent type before they are used in a `HLL_SKETCH_CREATE` function, especially if they will be merged later on.

### Syntax

SQL

```
HLL_SKETCH_CREATE(agg_col, [ log2k ] )
```

| Arguments | Data Type | Description |
|---|---|---|
| `agg_col` | All data types are supported. | An aggregated column for use when you create a sketch. |

| Arguments | Data Type | Description |
| --- | --- | --- |
| `log2k` | Integral literal | Optional.<br>This parameter controls the number of buckets in the HLL Sketch, which affects the accuracy and storage of the sketch. This value must be an integer literal in the range of [10, 16]. It cannot be a reference to a column.<br>By default, `log2k` values larger than 11 are compressed on disk using ZSTD compression.<br>For details about this parameter, see **HLL Accuracy with log2k Parameter**. |

### Example

This example uses `HLL_SKETCH_CREATE` as a window aggregate to generate 100 sketches that contain one value in each sketch.

SQL

```
SELECT MOD(c1, 9) AS m,
    HLL_SKETCH_CREATE(c1, 12) OVER (PARTITION BY c1) AS sketch
FROM sys.dummy100;
```

## HLL_SKETCH_UNION (aggregate function)

Merges multiple sketches in a single column into a unified sketch. All sketches must have the same precision. This function is an aggregate function and operates on a column.

### Syntax

SQL

```
HLL_SKETCH_UNION(agg_sketch_col)
```

| Arguments | Data Type | Description |
| --- | --- | --- |
| `agg_sketch_col` | `HLL_SKETCH<log2k>` | A column that contains multiple sketches to be merged into one sketch. |

### Example

This example performs two merges. First, this code uses `HLL_SKETCH_CREATE` as a window aggregate to generate 100 sketches that contain one value in each sketch. The code merges the 100 sketches into nine sketches, and then the final SELECT statement merges the nine sketches into a single sketch. Also, the example uses the `HLL_SKETCH_GET_ESTIMATE` function to retrieve the estimated distinct count from the merged sketches.

SQL

```
WITH hll_sketch AS (
    SELECT MOD(c1, 9) AS m,
        HLL_SKETCH_CREATE(c1) OVER (PARTITION BY c1) AS sketch
    FROM sys.dummy100
),
hll_merged AS (
    SELECT HLL_SKETCH_UNION(hll_sketch.sketch) AS sketch
    FROM hll_sketch
    GROUP BY m
)
SELECT HLL_SKETCH_GET_ESTIMATE(HLL_SKETCH_UNION(hll_merged.sketch))
FROM hll_merged;
```

*Output*: `97`

## HLL_SKETCH_UNION (scalar function)

Merges two sketches to a new combined sketch. This function is a scalar function and operates row-wise. The scalar function merges two sketch columns with heterogeneous precisions into a sketch with the lower of the two precisions.

### Syntax

SQL

```
HLL_SKETCH_UNION(sketch_col1, sketch_col2)
```

| Arguments | Data Type | Description |
|---|---|---|
| `sketch_col1` | `HLL_SKETCH<log2k>` | A column of HLL sketches |

| Arguments | Data Type | Description |
| --- | --- | --- |
| `sketch_col2` | `HLL_SKETCH<log2k>` | A column of HLL sketches |

### Example

This example creates two sketches from the dummy table. The first uses the default precision of 11, and the second uses a precision of 14. The second sketch is offset by 1000, so there are 2000 unique values being sketched overall.

The query merges the two sketches using the two argument scalar union, which combines them into a new sketch. This unified sketch has a precision of 11, the lower of the two input precisions.

The query then decodes the sketch, which has the expected result of 2000 ± 92.

SQL

```
SELECT HLL_SKETCH_GET_ESTIMATE(
        HLL_SKETCH_UNION(
            HLL_SKETCH_CREATE(c1),
            HLL_SKETCH_CREATE((c1 + 1000)::INT, 14)
        )
    ) as sketch_col
FROM sys.dummy1000;
```

*Output*: `2000 ± 92`

## HLL_SKETCH_GET_ESTIMATE

The `HLL_SKETCH_GET_ESTIMATE` scalar function converts a sketch into a distinct count estimate of a sketch value. Returns the distinct count estimate as a `BIGINT`.

To return a distinct count across a column of sketch values, you should first merge the sketches by using the `HLL_SKETCH_UNION` function.

### Syntax

SQL

```
HLL_SKETCH_GET_ESTIMATE(sketch)
```

| Arguments | Data Type | Description |
|---|---|---|
| `sketch` | `HLL_SKETCH<log2k>` | A sketch value to convert to an approximate distinct count. |

### Example

SQL

```
WITH hll_sketch AS (
    SELECT MOD(c1, 9) as m,
        HLL_SKETCH_CREATE(c1) OVER (PARTITION BY c1) AS sketch
    FROM sys.dummy100
),
hll_merged AS (
    SELECT HLL_SKETCH_UNION(hll_sketch.sketch) AS sketch
    FROM hll_sketch
    GROUP BY m
)
SELECT HLL_SKETCH_GET_ESTIMATE(HLL_SKETCH_UNION(hll_merged.sketch))
FROM hll_merged;
```

*Output*: `97`

## HLL_SKETCH_GET_ESTIMATE_BOUND

The `HLL_SKETCH_GET_ESTIMATE_BOUND` scalar function takes a `HLL_SKETCH` column or an integral `log2k` literal value and returns the resulting bounding 95-percent confidence interval error proportion as a `DOUBLE`. If you provide an integral `log2k` value, it must be an integral literal and cannot be a column.

### Syntax

```sql
HLL_SKETCH_GET_ESTIMATE_BOUND(sketch_or_integral)
```

| Arguments | Data Type | Description |
|---|---|---|
| `sketch_or_integral` | `HLL_SKETCH<log2k>` or integral literal | A sketch value, column, or an integral literal. |

### Example

```sql
SELECT HLL_SKETCH_GET_ESTIMATE_BOUND(HLL_SKETCH_CREATE(c1, 14))
FROM sys.dummy100;
```

*Output*: `0.0163`

## HLL_SKETCH_TO_STRING

The `HLL_SKETCH_TO_STRING` scalar function takes a `HLL_SKETCH` column or value and returns a string summary of the sketch.

### Syntax

```sql
HLL_SKETCH_TO_STRING(sketch)
```

| Arguments | Data Type | Description |
|---|---|---|
| `sketch` | `HLL_SKETCH<log2k>` | A sketch value or column to summarize as a string. |

### Example

SQL

```
SELECT HLL_SKETCH_TO_STRING(HLL_SKETCH_CREATE(c1)) AS summary
FROM sys.dummy10000;
```

*Output*:

Text

```
### HLL SKETCH SUMMARY:
Log2k                   : 11
Lower bound             : 9540.000000
Estimate                : 10000
Upper bound             : 10460.000000
Number of values seen   : 10000
Minimum index           : 114
Value at minimum index  : 0
Maximum index           : 1892
Value at maximum index  : 14
```

This summary contains this information:

- The `log2k` value. For more information, see **HLL Accuracy with log2k**.
- The lower, estimate, and upper bound of the sketch.
- The number of values seen in the sketch.
- The minimum and maximum bucket indexes and their values in the sketch.

ⓘ The output fields in this summary are for internal purposes, except for the `log2k` value.

# Geospatial Functions

Reference for Ocient OcientGeo geospatial functions, including constructors, measurement, spatial relationships, and spatiotemporal operators for GIS data.

The OcientAIQ™ Unified Data Platform has OcientGeo™ that supports three different geospatial geographies: `POLYGON`, `LINESTRING`, and `POINT`.

- A `POLYGON` can be constructed with a closed LINESTRING or an outer shell and array of inner rings.
- A `LINESTRING` represents a series of points connected by line segments. It can be constructed with either `LINESTRING` or `POINT` data types.
- A `POINT` represents a point in space defined by an (x, y) or (longitude, latitude) coordinate pair.

> Each `LINESTRING` or `POLYGON` value can be up to a maximum of 512 MB in size. This means a `LINESTRING` or `POLYGON` can contain approximately 32 million point values.

These supported geospatial data types require Well-Known Text (WKT) formatting. For formatting examples, see **Data Types** or **WKT Representation of Geometry**. The OcientGeo functionality reference also contains examples with supported formatting and syntax.

Each geospatial geography has a number of functions and operators that can be used in SQL queries to perform analyses. Some functions apply to specific geography types. For operators specific to geospatial data types, refer to **Geospatial Operators**.

OcientGeo uses the authalic radius of the Earth, 6371007.1810824 meters, as the reference for many measurement calculations.

> The authalic radius reference might cause slight differences in measurements compared to other geospatial systems that use a different radius definition.

## Geospatial Operators

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

OcientGeo supports special operators that perform operations on two different geographies. These can be used in queries to compare geographies or calculate values based on the geographies.

| Operator | Syntax | Purpose |
|---|---|---|
| intersects | `geoA && geoB` | Returns `TRUE` if the bounding box of geography A intersects with the bounding box of B. |
| contained | `geoA @ geoB` | Returns `TRUE` if the bounding box of geography A is contained within the bounding box of B. |
| equal | `geoA ~= geoB` | Returns `TRUE` if the bounding box of geography A is the same as bounding box of B. |
| contains | `geoA ~ geoB` | Returns `TRUE` if the bounding box of geography A contains the bounding box of B. |
| distance | `geoA <-> geoB` | Returns the distance in meters between the two geography parameters. |
| bounding box distance | `geoA <#> geoB` | Returns the distance in meters between the bounding box of the two geography parameters. |
| centroid distance | `geoA <<->> geoB` | Returns the distance in meters between the centroids of the two geography parameters. |

## Geospatial Functions Overview

OcientGeo supports many geospatial functions that operate on POINT, LINESTRING, and POLYGON values. Each function, its expected inputs, and return type are described in the following section.

## Geospatial Filtering

Queries that involve geospatial filtering can make use of functions in the **Spatial Relationships** section.

To optimize these queries, OcientGeo provides a `SPATIAL` index that you can apply to columns with geospatial data types. For details about the `SPATIAL` index, see **Secondary Indexes**.

## Attribute Functions

Attribute functions return descriptive information on the specified data set.

- ST_COORDDIM
- ST_DIMENSION
- ST_GEOMETRYTYPE
- ST_ISEMPTY
- ST_MEMSIZE
- ST_NDIMS
- ST_NDIMENSION
- ST_NPOINTS
- ST_NUMPOINTS
- ST_SRID
- ST_X
- ST_XMAX
- ST_XMIN
- ST_Y
- ST_YMAX
- ST_YMIN

## Conversion Functions

Conversion functions transform a specified operand to a different data type.

- ST_ASBINARY
- ST_ASWKB
- ST_ASGEOJSON
- ST_ASEWKT
- ST_ASLATLONTEXT
- ST_ASTEXT
- ST_ASWKT
- ST_GEOHASH

## Linestring Constructors

LINESTRING constructors use geospatial data to create a LINESTRING object.

- ST_LINEFROMTEXT
- ST_LINEFROMGEOJSON
- ST_LINEFROMWKB
- ST_LINEFROMEWKT
- ST_LINESTRING
- ST_MAKELINE

## Linestring Functions

LINESTRING functions can perform alterations or access descriptive information on LINESTRING objects.

- ST_ADDPOINT
- ST_ENDPOINT
- ST_LINEINTERPOLATEPOINT
- ST_LINELOCATEPOINT
- ST_LINESUBSTRING
- ST_POINTN
- ST_REMOVEPOINT
- ST_SETPOINT
- ST_STARTPOINT

## Point Constructors

POINT constructors use geospatial data to create a POINT object.

# Attribute Functions

Reference for OcientGeo attribute functions used to inspect, extract, and modify properties of geospatial geometries such as points, linestrings, and polygons.

OcientGeo™ attribute functions return descriptive information on the specified data set.

## ST_COORDDIM

ST_NDIMS and ST_NDIMENSION are aliases for this function.

Returns an `INTEGER` of the coordinate dimension of the specified geography.

### Syntax

```
SQL

ST_COORDDIM(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | The geospatial object used to calculate the dimensions. |

### Example

```
SQL

SELECT ST_COORDDIM(ST_POLYGON('POLYGON((1 1, 2 1, 2 2, 1 1))'));
```

*Output*: `2`

## ST_DIMENSION

Returns an `INTEGER` that represents the dimension of the specified geography. This table describes the result values of the `ST_DIMENSION` function.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| ST_DIMENSION Result Value | Dimension Type |
| --- | --- |
| `-1` | Empty geography value |
| `0` | `POINT` |
| `1` | `LINESTRING` |
| `2` | `POLYGON` |

The `ST_DIMENSION` function always returns `0` for non-empty `POINT` objects.

For non-empty `LINESTRING` and `POLYGON` objects, the `ST_DIMENSION` function returns the dimension value equal to the greatest dimension represented by their bounding points. For example, a `LINESTRING` or `POLYGON` object that contains only a single point returns `0`. Similarly, a `POLYGON` object can return `1` if it contains insufficient points to represent a closed polygon.

### Syntax

SQL

```
ST_DIMENSION(geo)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | The geospatial object used to calculate the dimensions. |

### Examples

In this example, the function evaluates a `LINESTRING` with an empty `POINT` value.

SQL

```
SELECT ST_DIMENSION(ST_LINESTRING('POINT EMPTY'));
```

*Output*: `-1`

In this example, the function evaluates a `LINESTRING` with a single `POINT` value.

```sql
SELECT ST_DIMENSION(ST_LINESTRING('ST_POINT(0 0)'));
```

*Output*: `0`

This example evaluates an empty `LINESTRING`.

```sql
SELECT ST_DIMENSION(ST_LINESTRING('LINESTRING EMPTY'));
```

*Output*: `-1`

In this example, the function again evaluates a `LINESTRING` with a single `POINT` value.

```sql
SELECT ST_DIMENSION(ST_LINESTRING('LINESTRING(0 0)'));
```

*Output*: `0`

In this example, the function evaluates a `LINESTRING` with multiple `POINT` values.

```sql
SELECT ST_DIMENSION(ST_LINESTRING('LINESTRING(0 0, 1 1)'));
```

*Output*: `1`

This example evaluates an empty `POLYGON`.

```sql
SELECT ST_DIMENSION(ST_POLYGON('POLYGON EMPTY'));
```

*Output*: `-1`

This example evaluates a `POLYGON` with a single `POINT`.

```
SQL

SELECT ST_DIMENSION(ST_POLYGON('POLYGON((1 1))'));
```

*Output*: `0`

This example evaluates a `POLYGON` with two `POINT` values.

```
SQL

SELECT ST_DIMENSION(ST_POLYGON('POLYGON((0 0, 1 1))'));
```

*Output*: `1`

This example evaluates a `POLYGON` with multiple `POINT` values, enough to close the `POLYGON`.

```
SQL

SELECT ST_DIMENSION(ST_POLYGON('POLYGON((0 0, 1 0, 1 1, 0 0))'));
```

*Output*: `2`

# ST_GEOMETRYTYPE

Returns a `STRING` that represents the geometry of the input geospatial value. Supported values are `ST_POINT`, `ST_LINESTRING`, and `ST_POLYGON`. This function enforces the same strict dimension types as the **ST_DIMENSION** function. If `geo` is NULL, then the function returns NULL.

### Syntax

```
SQL

ST_GEOMETRYTYPE(geo)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, `POLYGON` | A geospatial value to be identified by its dimension type. |

### Example

```
SQL

SELECT ST_GEOMETRYTYPE(ST_POINT(1, 2));
```

*Output*: `ST_POINT`

## ST_ISEMPTY

Returns `TRUE` if the specified geography value is empty, such as `'POLYGON EMPTY'`. A NULL input value returns NULL.

### Syntax

```
SQL

ST_ISEMPTY(geo)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, `POLYGON` | A geospatial value to be examined if it is empty. |

### Example

```
SQL

SELECT ST_ISEMPTY(ST_POLYGON('POLYGON EMPTY'));
```

*Output*: `TRUE`

# ST_MEMSIZE

Returns an `INTEGER` representing the number of bytes in memory required to store the specified geography.

### Syntax

```
SQL

ST_MEMSIZE(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, `POLYGON` | A geospatial value to be measured by its data memory. |

### Example

```
SQL

SELECT ST_MEMSIZE(ST_POINT(1,1));
```

*Output*: `16`

# ST_NDIMS or ST_NDIMENSION

Alias for **ST_COORDDIM**.

# ST_NPOINTS or ST_NUMPOINTS

Returns an `INTEGER` representing the number of `POINT` values in a specified geography.

If the specified value is a `POLYGON`, this function counts the number of `POINT` values in both the exterior and any holes.

### Syntax

© 2026 Ocient, Inc

SQL

```
ST_NPOINTS(geo)
```

SQL

```
ST_NUMPOINTS(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, `POLYGON` | A geospatial value to be examined for its count of `POINT` values. |

### Example

SQL

```
SELECT ST_NPOINTS(
   ST_POLYGON(
      'POLYGON((1 2, 1 3, 1 2))'));
```

*Output*: `3`

## ST_SRID

Returns the EPSG code of the spatial reference identifier (SRID) of the input geography. All Ocient® geographies are of type GCS WGS 84, which is identified by the value 4326. There is no way to set a different SRID.

### Syntax

SQL

```
ST_SRID(geo)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, `POLYGON` | A geospatial value to be analyzed for its EPSG code. |

### Example

```
SQL

SELECT ST_SRID(ST_MAKEPOINT(1.1, 3.11));
```

*Output*: `4326`

## ST_X

Returns the x value, or longitude, of the specified `POINT`. The returned value is a `DOUBLE` type.

### Syntax

```
SQL

ST_X(point)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `point` | `POINT` | A geospatial point to be analyzed for its x value, the longitude. |

### Example

```
SQL

SELECT ST_X(ST_POINT(3, 5));
```

*Output*: `3`

# ST_XMAX

Returns the maximum x value of the specified geography. The returned value is a `DOUBLE` type.

### Syntax

```
SQL

ST_XMAX(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, `POLYGON` | One or more geospatial points to be analyzed for the maximum x value. |

### Example

In this example, the `ST_XMAX` function returns `2` because it is the largest x value of the specified points.

```
SQL

SELECT ST_XMAX(
        ST_POLYGON(ST_LINESTRING('LINESTRING(2 5, 1 2, 1 4, 0 3)')));
```

*Output*: `2`

# ST_XMIN

Returns the minimum x value of the specified geography.

### Syntax

```
SQL

ST_XMIN(geo)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, `POLYGON` | One or more geospatial points to be analyzed for the minimum x value. |

### Example

In this example, the `ST_XMIN` function returns `0` because it is the smallest x value of the specified points.

SQL

```
SELECT ST_XMIN(
        ST_POLYGON(ST_LINESTRING('LINESTRING(2 5, 1 2, 1 4, 0 3)')));
```

*Output*: `0`

## ST_Y

Returns the y value, or latitude, of the specified `POINT`. The returned value is a `DOUBLE` type.

### Syntax

SQL

```
ST_Y(point)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `point` | `POINT` | A geospatial point to be analyzed for its y value, the latitude. |

### Example

SQL

```
SELECT ST_Y(ST_POINT(3, 5));
```

*Output*: `5`

# ST_YMAX

Returns the maximum y value of the specified geography.

### Syntax

```
SQL

ST_YMAX(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, `POLYGON` | One or more geospatial points to be analyzed for the maximum y value. |

### Example

In this example, the `ST_YMAX` function returns `5` because it is the largest y value of the specified points.

```
SQL

SELECT ST_YMAX(
        ST_POLYGON(ST_LINESTRING('LINESTRING(2 5, 1 2, 1 4, 0 3)')));
```

*Output*: `5`

# ST_YMIN

Returns the minimum y value of the specified geography.

### Syntax

```
SQL

ST_YMIN(geo)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, `POLYGON` | One or more geospatial points to be analyzed for the minimum y value. |

### Example

In this example, the `ST_YMIN` function returns `2` because it is the smallest y value of the specified points.

SQL

```
SELECT ST_YMIN(
        ST_POLYGON(ST_LINESTRING('LINESTRING(2 5, 1 2, 1 4, 0 3)')));
```

*Output*: `2`

# Conversion Functions

Reference for OcientGeo conversion functions that transform geospatial values between WKT, WKB, GeoJSON, and Ocient native point, linestring, and polygon types.

OcientGeo™ conversion functions transform a specified operand to a different data type.

## ST_ASBINARY

Alias of ST_ASWKB.

Returns the well-known binary (WKB) representation of the specified geography.

### Syntax

```
SQL

ST_ASBINARY(geo [, XDR_or_NDR ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | The geospatial object used to calculate the dimensions. |
| `XDR_or_NDR` | `CHAR` | Optional. This argument determines whether the resulting WKB is in little endian (NDR) or big endian (XDR) format.<br>If you specify this argument, it must be either `XDR` or `NDR`. Otherwise, it defaults to `NDR`. |

### Example

```
SQL

SELECT ST_ASBINARY(ST_POINT(2, 2), 'NDR');
```

*Output*: `01010000000000000000000040000000000000040`

# ST_ASGEOJSON

Returns the GeoJSON representation of the specified geography using the **IETF standards**.

SQL

```
ST_ASGEOJSON( geo [, planar_conversion ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | The geospatial object used to create a GeoJSON representation.<br>ℹ The GeoJSON specification has certain requirements for a `LINESTRING` and `POLYGON`.<br>In keeping with this specification, a `POLYGON` instance that represents a `LINESTRING` results in a `LINESTRING` GeoJSON instance.<br>Similarly, a `POLYGON` instance that represents a `POINT` results in a `POINT` GeoJSON instance.<br>A `LINESTRING` instance that represents a `POINT` results in a `POINT` GeoJSON instance.<br>Unlike the GeoJSON specification, a specified `POLYGON` does not need to follow the Right-Hand Rule. If a specified `POLYGON` contains any holes that are not valid `POLYGON` objects, then the function omits those holes in the resulting GeoJSON instance. |
| `planar_conversion` | `BOOLEAN` | Optional. A Boolean value that determines if the geodesic edges of the specified geography are converted to planar representation before the function applies the GeoJSON format. IETF® standards state that all GeoJSON objects are to be interpreted as explicitly planar. This argument allows preservation of the original geodesic shape.<br>If `planar_conversion` is specified `TRUE`, points will be added such that the resulting GeoJSON represents a planar shape within 10m of the original geospatial object. Additionally, if the original geospatial object crossed the international dateline, it will be split at the point where it crosses. This will generate a GeoJSON object of either `MultiLineString` or `MultiPolygon` type, depending on the original type of the geospatial object.<br>If you do not specify this argument, the value defaults to `FALSE`. |

## Examples

This example converts a `POINT` value into a GeoJSON representation.

SQL

```
SELECT ST_ASGEOJSON(ST_POINT(2, 2), false);
```

*Output*:

Text

```
{"type":"Point","coordinates":[2,2]}
```

This example converts an empty `POINT` value.

SQL

```
SELECT ST_ASGEOJSON(ST_POINTFROMTEXT('POINT EMPTY'), false);
```

*Output*:

Text

```
{"type":"Point","coordinates":[]}
```

This example converts a `LINESTRING` value into a GeoJSON representation.

SQL

```
SELECT ST_ASGEOJSON(ST_LINESTRING(ST_POINT(1.234, 2),ST_POINT(3.456, 5));
```

*Output*:

Text

```
{"type":"LineString","coordinates":[[1.234,2],[3.456,5]]}
```

This example again converts a `LINESTRING` value.

SQL

```
SELECT ST_ASGEOJSON(ST_LINESTRING(ARRAY[ST_POINT(1.234, 2)]);
```

*Output*:

Text

```
{"type":"Point","coordinates":[1.234,2]}
```

This example converts an empty `LINESTRING` value into a GeoJSON representation.

SQL

```
SELECT ST_ASGEOJSON(ST_LINEFROMTEXT('LINESTRING EMPTY'), false);
```

*Output*:

Text

```
{"type":"LineString","coordinates":[]}
```

This example converts a `POLYGON` value into a GeoJSON representation.

SQL

```
SELECT ST_ASGEOJSON(
    ST_POLYGON(
        ARRAY [ST_POINT(1.234, 2),ST_POINT(3.456, 5),ST_POINT(5.678,         2),ST_
        ARRAY [ARRAY[ST_POINT(2,2.5),ST_POINT(2.1,2.6),ST_POINT(2.2,2.5),ST_POINT(2
        ARRAY [ST_POINT(3,2.5),ST_POINT(3.1,2.6),ST_POINT(3.2,2.5),ST_POINT(3,2.5)]
```

*Output*:

Text

```
{"type":"Polygon","coordinates":[[[1.234,2],[3.456,5],[5.678,2],[1.234,2]],[[2,2.5]
```

This example again converts a `POLYGON` value.

SQL

```
SELECT ST_ASGEOJSON(
    ST_POLYGON(
        ARRAY [ST_POINT(1.234, 2),ST_POINT(3.456, 5),ST_POINT(5.678, 2),ST_POINT(1.
        ARRAY [ARRAY[ST_POINT(2,2.5),ST_POINT(2.1,2.6),ST_POINT(2.2,2.5),ST_POINT(3
        ARRAY [ST_POINT(3,2.5),ST_POINT(3.2,2.5),ST_POINT(3,2.5)]]), false);
```

*Output*:

Text

```
{"type":"Polygon","coordinates":[[[1.234,2],[3.456,5],[5.678,2],[1.234,2]]]}
```

This example converts a two-point `POLYGON`, which results in a `LINESTRING` type in the GeoJSON representation.

SQL

```
SELECT ST_ASGEOJSON(
        ST_POLYGON(
            ST_LINESTRING(ST_POINT(1.234, 2), ST_POINT(3.456, 5))),
        false);
```

*Output*:

Text

```
{"type":"LineString","coordinates":[[1.234,2],[3.456,5]]}
```

This example converts a single-point `POLYGON`, which results in a `POINT` type in the GeoJSON representation.

SQL

```
SELECT ST_ASGEOJSON(ST_POLYGON(ST_POINT(1.234, 2)), false);
```

*Output*:

```
Text
{"type":"Point","coordinates":[1.234,2]}
```

This example converts an empty `POLYGON` value into a GeoJSON representation.

```
SQL
SELECT ST_ASGEOJSON(ST_POLYGONFROMTEXT('POLYGON EMPTY'), false);
```

*Output*:

```
Text
{"type":"Polygon","coordinates":[]}
```

# ST_ASLATLONTEXT

Returns a string that represents geographic coordinates of a specified `POINT` in the specified format.

```
SQL
ST_ASLATLONTEXT(point, [ output_format ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `point` | `POINT` | A POINT value used to calculate geographic coordinates. If `point` is NULL, then this function returns NULL. |
| `output_format` | `CHAR` | Optional. A string that includes option flags to set the format and decimal precision for the output of the coordinates.<br>Option flags must be uppercase to be recognized.<br>Accepted option flags are:<br>`D` — Represents coordinate degrees. If you specify a format string for `output_format`, this value is required. If `M` is omitted, this option flag sets the decimal precision.<br>`M` — Represents minutes of latitude or longitude |

| Argument | Data Type | Description |
| --- | --- | --- |
| | | distance. If `S` is omitted, this option flag sets the decimal precision.<br>`S` — Represents seconds of latitude or longitude distance.<br>`C` — Represents the cardinal direction. If you specify this value, the appropriate cardinal direction is represented as N/S/E/W. If you omit this value, coordinates that are south or west are represented as negative values while east or north remain positive values.<br>For all option flags besides `C`, you can repeat the option characters and use them with decimal points to set the format and decimal precision. The number of characters after the decimal point indicates the precision, while the number of characters before the decimal indicates the total width of the formatted number, including the decimal POINT.<br>If the formatted number is shorter than the requested width, the system pads the value with leading spaces.<br>Characters other than `D`, `M`, `S`, `C`, and `.` are passed through as string characters.<br>If you do not specify `output_format` or leave it as empty, the value defaults to the format `D°M''S.SSS"C`. |

### Example

SQL

```
SELECT ST_ASLATLONTEXT(ST_POINT(10.2342342,-2.32498), 'D.D degrees MM.MM minutes C'
```

*Output*: `'2.0 degrees 19.50 minutes S 10.0 degrees 14.05 minutes E'`

# ST_ASTEXT

Alias of ST_ASWKT and ST_EWKT.

Returns the well-known text (WKT) representation of the specified geography.

If you use `ST_ASEWKT`, the database prepends the resultant string with `SRID=4326;`.

SQL

```
ST_ASTEXT(geo)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object that is to be returned as a WKT value.<br>If you specify a `LINESTRING` or `POLYGON` that contains a single `POINT`, the function returns the WKT representation as a `POINT`.<br>If you specify a `POLYGON` that has an exterior that is not closed, the function returns the WKT representation as a `LINESTRING`. |

### Example

```
SQL

SELECT ST_ASTEXT(ST_POLYGON(ST_LINESTRING('LINESTRING(1 2, 1 3, 1 3, 1 2)')));
```

*Output*: `POLYGON((1 2, 1 3, 1 3, 1 2))`

## ST_ASEWKT

For usage, see **ST_ASTEXT**.

## ST_ASWKT

Alias of **ST_ASTEXT**.

## ST_ASWKB

Alias of **ST_ASBINARY**.

## ST_GEOHASH

Returns a string that represents the geohash of the input `POINT`. This function also accepts an optional second argument to specify the length of the geohash result.

If you specify any argument as NULL, then the function returns NULL.

```
SQL

ST_GEOHASH(point [, precision ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `point` | `POINT` | A `POINT` value that is to be converted into a geohash. |
| `precision` | `INTEGER` | Optional. A numeric value that specifies the geohash precision, which determines the length of the output string.<br>This number must be in the range of 1 to 20. If you do not specify this value, `precision` defaults to 20. |

### Example

```
SQL

SELECT ST_GEOHASH(ST_POINT(-126, 48));
```

*Output*: `c0w3hc0w3hf1s70w3hf1s70w3`

# Linestring Constructors

Construct linestring geometries in OcientGeo using ST_LINESTRING and related functions to build spatial line objects from point coordinates and arrays.

OcientGeo™ LINESTRING constructors use geospatial data to create a LINESTRING object.

## ST_LINEFROMTEXT

Alias for ST_LINESTRING(CHAR).

Creates a `LINESTRING` from a specified `CHAR`. The `CHAR` must be a `LINESTRING` value in WKT format.

### Syntax

```sql
ST_LINEFROMTEXT(char)
```

| Argument | Data Type | Description |
|---|---|---|
| `char` | `CHAR` | A character value in WKT format to be used to create a `LINESTRING`. |

### Example

```sql
SELECT ST_LINEFROMTEXT('LINESTRING(1 2)');
```

*Output*: `LINESTRING(1.000000 2.000000)`

## ST_LINEFROMWKB

Alias for ST_LINESTRING(BINARY).

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Creates a `LINESTRING` from the specified `BINARY`. The `BINARY` value must be a `LINESTRING` in WKB format.

### Syntax

```sql
ST_LINEFROMWKB(binary)
```

| Argument | Data Type | Description |
|---|---|---|
| `binary` | `BINARY` | A binary value in WKB format to be used to create a `LINESTRING`. |

### Example

```sql
SELECT ST_LINEFROMWKB(
        BINARY(
'0x0102000000020000000000000000f03f0000000000000040000000000000084000000000000010
        )
    );
```

*Output*: `LINESTRING(1 2,3 4)`

## ST_LINEFROMEWKT

Creates a `LINESTRING` from the specified `CHAR`.

The `CHAR` value must be a `LINESTRING` in EWKT format.

`ST_LINEFROMEWKT` is functionally the same as `ST_LINESTRING(CHAR)`.

The input string must include an `SRID=…;` value. However, the database ignores this component as all Ocient® geography types are SRID 4326.

### Syntax

```sql
ST_LINEFROMEWKT('SRID=value;char')
```

| Argument | Data Type | Description |
|---|---|---|
| `char` | `CHAR` | A `LINESTRING` value in WKT format to be used to create a `LINESTRING`.<br>To function properly, you must prefix this argument with an SRID value in the same string. |
| `value` | `INTEGER` | Any integer value. This is required, however, the database ignores this component and defaults to SRID 4326. |

### Example

```sql
SELECT ST_LINEFROMEWKT('SRID=4326;LINESTRING(1 2)');
```

*Output*: `LINESTRING(1.000000 2.000000)`

## ST_LINEFROMGEOJSON

Creates a `LINESTRING` represented by the specified GeoJSON. The specified GeoJSON can represent a GeoJSON `POINT` or `LINESTRING` type.

Valid GeoJSON formats follow IETF® **standards**, and you can generate them by using **ST_ASGEOJSON**. If you specify an invalid GeoJSON, the behavior of the function is undefined.

### Syntax

```sql
ST_LINEFROMGEOJSON(geojson [, geodesic ])
```

| Argument | Data Type | Description |
|---|---|---|
| `geojson` | `CHAR` | A GeoJSON value that represents a `POINT` or `LINESTRING` type that is used to create a `LINESTRING`.<br>If `geojson` is NULL, the function returns NULL. |
| `geodesic` | `BOOLEAN` | Optional. A `BOOLEAN` value that determines if the specified `geojson` should be converted from a planar to a geodesic representation.<br>If you specify `geodesic` as `TRUE`, the function adds points to the resulting `LINESTRING` such that it remains within 10 meters of the original planar line.<br>If unspecified, `geodesic` defaults to `FALSE`.<br>If `geodesic` is NULL, the function returns NULL. |

### Examples

In this example, the function converts an empty GeoJSON value of a `LINESTRING`.

SQL

```
SELECT ST_LINEFROMGEOJSON('{"type":"LineString","coordinates":[]}',false);
```

*Output*: `LINESTRING EMPTY`

In this example, the function converts a GeoJSON value of a `LINESTRING`.

SQL

```
SELECT ST_LINEFROMGEOJSON(
        '{"type":"LineString","coordinates":[[1,1],[1,5],[5,5],[5,1]]}',
        false);
```

*Output*: `LINESTRING(1 1, 1 5, 5 5, 5 1)`

## ST_LINESTRING

Alias for ST_MAKELINE.

Creates a `LINESTRING` based on the specified inputs.

## ST_LINESTRING(geoArray)

Creates a `LINESTRING` from the specified array of either `LINESTRING` or `POINT` values.

### Syntax

```
SQL

ST_LINESTRING(geo_array)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo_array` | `ARRAY` of geographies, either `LINESTRING` or `POINT` values. | An array of `LINESTRING` or `POINT` values to be used to create a unified `LINESTRING`. |

### Example

```
SQL

SELECT ST_LINESTRING(
        ST_LINESTRING [](ST_LINESTRING(ST_POINT(1, 2), ST_POINT(3, 4))));
```

*Output*: `LINESTRING(1.000000 2.000000, 3.000000 4.000000)`

## ST_LINESTRING(binary)

Creates a `LINESTRING` from the specified `BINARY`. The `BINARY` value must be a `LINESTRING` in WKB format.

### Syntax

```
SQL

ST_LINESTRING(binary)
```

| Argument | Data Type | Description |
|---|---|---|
| `binary` | `BINARY` | A `BINARY` value to be used to create a `LINESTRING`. The `BINARY` value must be a `LINESTRING` in WKB format. |

### Example

```sql
SELECT ST_LINESTRING(BINARY('0x0102000000020000000000000000f03f000000000000004000
```

*Output*: `LINESTRING(1 2,3 4)`

## ST_LINESTRING(char)

Creates a `LINESTRING` from the specified `CHAR`. The `CHAR` value must be a `LINESTRING` in WKT format.

### Syntax

```sql
ST_LINESTRING(char)
```

| Argument | Data Type | Description |
|---|---|---|
| `char` | `CHAR` | A `CHAR` value to be used to create a `LINESTRING`. The argument must be a `LINESTRING` in WKT format. |

### Example

```sql
SELECT ST_LINESTRING('LINESTRING(1 2)');
```

*Output*: `LINESTRING(1.000000 2.000000)`

## ST_LINESTRING(geo1, geo2)

Creates a `LINESTRING` consisting of two separate geographic arguments, both of which must be either a `POINT` or `LINESTRING`. You can mix geographic types, meaning one argument can be a `POINT` while the other is a `LINESTRING`.

### Syntax

```sql
ST_LINESTRING(geo1, geo2)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1`, `geo2` | `POINT` or `LINESTRING` | Two separate geographic arguments to be consolidated into a single `LINESTRING`.<br><br>Inputs can be the same type or one of each. |

### Example

```sql
SELECT ST_LINESTRING(ST_POINT(1, 2), ST_POINT(1,3));
```

*Output*: `LINESTRING(1.000000 2.000000, 1.000000 3.000000)`

# ST_MAKELINE

Alias for **ST_LINESTRING**.

## ST_MAKELINE(geo1, geo2)

Alias for **ST_LINESTRING(geo1, geo2)**.

## ST_MAKELINE(CHAR)

Alias for **ST_LINESTRING(char)**.

## ST_MAKELINE(geoArray)

Alias for **ST_LINESTRING(geoArray)**.

# Linestring Functions

Reference for OcientGeo linestring functions to measure, transform, and inspect linear spatial geometries including length, projection, and conversion.

OcientGeo™ LINESTRING functions can perform alterations or access descriptive information on LINESTRING objects.

## ST_ADDPOINT

Adds a `POINT` to the given `LINESTRING` at the specified 0-indexed location.

### Syntax

SQL

```
ST_ADDPOINT(geo_linestring, geo_point_to_add [, location ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo_linestring` | `LINESTRING` | A linestring to be altered by adding the `geo_point_to_add` at a specified location.<br>The function throws an error if `geo_linestring` is any data type except for `LINESTRING` or NULL. |
| `geo_point_to_add` | `POINT` | A point value to be added to the `geo_linestring`. |
| `location` | `INTEGER` | Optional. Represents a numeric 0-indexed location in the `geo_linestring` where `geo_point_to_add` is appended.<br>If you do not specify this value, the function defaults to appending the `geo_point_to_add` argument to the end of `geo_linestring`. A location value of -1 also appends to the end.<br>The function throws an error if the `location` argument is outside the bounds of the `geo_linestring` or if it is a value of less than -1. |

### Example

```sql
SELECT ST_ADDPOINT(
        ST_LINESTRING('LINESTRING(1 2, 1 3)'),
        ST_POINT(1, 4),
        1);
```

*Output*: `LINESTRING(1.000000 2.000000, 1.000000 4.000000, 1.000000 3.000000)`

# ST_ENDPOINT

Returns the endpoint of a specified `LINESTRING`. The returned value is a `POINT`.

### Syntax

```sql
ST_ENDPOINT(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `LINESTRING` | A line to be computed to return its endpoint.<br>If this value is a `POLYGON`, `POINT`, or is empty, then the function returns NULL.<br>If this value is a non-geospatial type, the function throws an error. |

### Example

```sql
SELECT ST_ENDPOINT(ST_LINESTRING('LINESTRING(1 2, 1 3, 1 4)'));
```

*Output*: `POINT(1,4)`

# ST_LINEINTERPOLATEPOINT

Returns a `POINT` along a `LINESTRING` based on a specified fraction of its total length.

### Syntax

```
SQL

ST_LINEINTERPOLATEPOINT(line, fraction)
```

| Argument | Data Type | Description |
|---|---|---|
| `line` | `LINESTRING` | A line used to compute an interpolated point. |
| `fraction` | `DOUBLE` | A decimal value between `0` and `1` that represents a fraction of the total length of the `line`. The function returns a point at this fraction of the length.<br>The function throws an error if this value is not between `0` and `1`. |

### Example

In this example, the function computes a point halfway (0.5) along the specified line.

```
SQL

SELECT ST_LINEINTERPOLATEPOINT(ST_LINESTRING('LINESTRING(1 2, 2 1)'), 0.5);
```

*Output*: `POINT(1.5 1.5)`

## ST_LINELOCATEPOINT

Similar to **ST_LINEINTERPOLATEPOINT**, this function computes a fraction based on where a specified `POINT` is located along the length of a specified `LINESTRING`.

### Syntax

```
SQL

ST_LINELOCATEPOINT(line, point)
```

| Argument | Data Type | Description |
|---|---|---|
| `line` | `LINESTRING` | A `LINESTRING` used to compute a fraction based on the interpolated `point` value. |
| `point` | `POINT` | A `POINT` used to calculate a fraction based on where it is located along the `line` value.<br>If the function cannot interpolate this value from the `line`, the function returns `0.0`. |

### Example

In this example, the function computes a fraction that represents where the point (1.5, 1.5) lies along the line.

SQL

```
SELECT ST_LINELOCATEPOINT(
        ST_LINESTRING('LINESTRING(1 2, 2 1)'),
        ST_POINT(1.5, 1.5));
```

*Output*: `0.5`

## ST_LINESUBSTRING

Returns a `LINESTRING` that is a substring of a specified line that starts and ends at the specified fractions of its total length.

### Syntax

SQL

```
ST_LINESUBSTRING(line, start_fraction, end_fraction)
```

| Argument | Data Type | Description |
|---|---|---|
| `line` | `LINESTRING` | A `LINESTRING` used to compute a substring line based on the `start_fraction` and `end_fraction` values. |
| `start_fraction` | `DOUBLE` | A decimal value between `0` and `1` that represents a fractional point of the total length of the `line`. The function uses this fractional point as the start point for the |

| Argument | Data Type | Description |
| --- | --- | --- |
| | | substring.<br>The function throws an error if the `start_fraction` is greater than the `end_fraction` |
| `end_fraction` | `DOUBLE` | A decimal value between `0` and `1` that represents a fractional point of the total length of `line`. The function uses this fractional point as the endpoint for the substring. |

### Example

In this example, the function generates a subsection of the provided linestring, spanning from the `start_fraction` value (0.5) that represents the halfway point of the original linestring, to the `end_fraction` value (1.0) that represents the endpoint.

SQL

```
SELECT ST_LINESUBSTRING(ST_LINESTRING('LINESTRING(1 2, 2 1)'), 0.5, 1.0);
```

*Output*: `LINESTRING(1.50 1.50, 2.0 1.0)`

## ST_POINTN

Returns the `POINT` value at a specified index of the specified `LINESTRING`. If out of bounds, the function returns NULL.

### Syntax

SQL

```
ST_POINTN(geo, index)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `LINESTRING` | A `LINESTRING` that is used to return one of its point values.<br>If you specify a `POINT` or `POLYGON` value, this function returns NULL. |
| `index` | `INTEGER` | An index location of one of the point values in the `geo` value.<br>This is one-based, meaning the first index location starts |

| Argument | Data Type | Description |
| --- | --- | --- |
| | | at `1`.<br>Negative values count backward from the end of the linestring. In other words, an index value of `-1` returns the last point value. |

### Example

SQL

```
SELECT ST_POINTN(
        ST_LINESTRING(
            ST_POINT [](ST_POINT(1, 2), ST_POINT(1, 3), ST_POINT(1, 4))),
        3);
```

*Output*: `ST_POINT(1,4)`

## ST_REMOVEPOINT

Removes a `POINT` value at a specified index from the specified line.

### Syntax

SQL

```
ST_REMOVEPOINT(geo, index)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `LINESTRING` | A `LINESTRING` that is to be altered by removing one of its point values. |
| `index` | `INTEGER` | An index of one of the point values in the `geo` value. This is zero-based, meaning the first index location starts at `0`, and the last index is `length(geo)-1`. |

### Example

```sql
SELECT ST_REMOVEPOINT(ST_LINESTRING('LINESTRING(1 2, 1 3, 1 4)'), 1);
```

*Output*: `LINESTRING(1.0 2.0, 1.0 4.0)`

# ST_SETPOINT

Replaces a `POINT` value in a specified `LINESTRING` at a specified index. The function returns the altered `LINESTRING` with the replaced point.

### Syntax

```sql
ST_SETPOINT(geo, index, geo_point_to_replace)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `LINESTRING` | A `LINESTRING` that is to be altered with a new point value. |
| `index` | `INTEGER` | An index location of one of the point values in the `geo` linestring.<br>This is zero-based, meaning the first index location starts at `0`.<br>Negative values count backward from the end of the `geo` value. In other words, an index value of `-1` returns the last point value. |
| `geo_point_to_replace` | `POINT` | A `POINT` value to replace the value at the specified `index` location.<br>If this value is not a `POINT` type or NULL, the function throws an error. |

### Example

In this example, the function replaces the point value located at the `-2` index location, meaning it is the second from the last in the sequence.

```sql
SELECT ST_SETPOINT(
        ST_LINESTRING('LINESTRING(1 2, 1 3, 1 4)'),
        -2,
        ST_POINT(1, 5));
```

*Output*: `LINESTRING(1.000000 2.000000, 1.000000 5.000000, 1.000000 4.000000)`

# ST_STARTPOINT

Returns the starting `POINT` value of the line. If this value is empty, the function returns NULL. If you specify a `POLYGON`, `POINT`, or NULL, then the function returns NULL. If you specify a non-geography value, the function throws an error.

### Syntax

```sql
ST_STARTPOINT(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `LINESTRING` | A line to be computed to return its starting point.<br>If this value is a `POLYGON`, `POINT`, or is empty, then the function returns NULL.<br>If this value is a non-geospatial type, the function throws an error. |

### Example

```sql
SELECT ST_STARTPOINT(ST_LINESTRING('LINESTRING(1 2, 1 3, 1 4)'));
```

*Output*: `ST_POINT(1,2)`

# Point Constructors

Construct point geometries in OcientGeo using ST_POINT and related functions to create spatial point values from latitude and longitude coordinate pairs.

OcientGeo™ POINT constructors use geospatial data to create a POINT object.

## ST_CENTROID

Returns a `POINT` that is the geographic center of mass of a specified geospatial object.

The geographic center of mass is calculated by taking the average of all points on a three-dimensional sphere, projecting the resultant point onto the sphere, and converting it back to latitude and longitude coordinates.

### Syntax

SQL

```
ST_CENTROID( geo [, use_spheroid ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object that the function analyzes to compute its geometric center. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If this argument is `TRUE`, the function computes the centroid using a spheroid model instead of a spherical model.<br>If you do not specify this value, the value defaults to `FALSE`. |

### Example

SQL

```
SELECT ST_CENTROID(ST_POLYGON('POLYGON((1 1, 2 1, 2 2, 1 1))'));
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

*Output*: `POINT(1.66 1.33)`

# ST_GEOGPOINT

Alias for `ST_POLYGON(ST_LINESTRING(ARRAY(ST_POINT(lon, lat))))`.

Creates and returns a `POLYGON` geography with a single point, defined by the longitude and latitude specified for the function.

### Syntax

```
SQL

ST_GEOGPOINT(lon, lat)
```

| Argument | Data Type | Description |
|---|---|---|
| `lon` | `DOUBLE` | A longitude coordinate to be used to create a `POLYGON` with a single point. |
| `lat` | `DOUBLE` | A latitude coordinate to be used to create a `POLYGON` with a single point. |

### Example

```
SQL

SELECT ST_GEOGPOINT(41.882548,-87.63922);
```

*Output*: `POLYGON((41.882548 -87.63922))`

# ST_MAKEPOINT

Alias for **ST_POINT**.

# ST_POINT

Creates a `POINT` from the specified input arguments.

## ST_POINT(binary)

Alias for ST_POINTFROMWKB.

Creates a `POINT` from the specified `BINARY` value, which must represent a point in WKB format.

### Syntax

```
SQL

ST_POINT(binary)
```

| Argument | Data Type | Description |
|---|---|---|
| `binary` | `BINARY` | A binary value in WKB format that represents a `POINT`. |

### Example

```
SQL

SELECT ST_POINT(BINARY('0x0101000000000000000000f03f0000000000000040'));
```

*Output*: `POINT(1 2)`

## ST_POINT(char)

Creates a `POINT` from a `CHAR` value that represents a point in WKT format.

### Syntax

```
SQL

ST_POINT(char)
```

| Argument | Data Type | Description |
|---|---|---|
| `char` | `CHAR` | A `CHAR` that represents a `POINT` in WKT format. |

### Example

```sql
SELECT ST_POINT('POINT(1 2)');
```

*Output*: `POINT(1 2)`

## ST_POINT(lon, lat)

Creates a `POINT` defined with the values provided for the longitude and latitude coordinates.

### Syntax

```sql
ST_POINT(lon, lat)
```

| Argument | Data Type | Description |
|---|---|---|
| `lon` | `DOUBLE` | A `DOUBLE` value that represents a longitude coordinate. |
| `lat` | `DOUBLE` | A `DOUBLE` value that represents a latitude coordinate. |

### Example

```sql
SELECT ST_POINT(87.6386, 41.8843);
```

*Output*: `POINT(87.6386 41.8843)`

# ST_POINTFROMEWKT

Alias for **ST_POINT**.

Creates a `POINT` using an EWKT-formatted `CHAR` as an input argument.

### Syntax

```sql
ST_POINTFROMEWKT(srid_char)
```

| Argument | Data Type | Description |
|---|---|---|
| `srid_char` | `CHAR` | A string that includes a Spatial Reference Identifier (SRID) value and an EWKT-formatted value that represents a `POINT`.<br>Separate the values in the string by a semicolon using this format:<br>`'SRID = value; point_value'`<br>The input string must include the `SRID = value;` component. However, the database ignores this component as all Ocient® geography types are `SRID = 4326`. |

### Example

```sql
SELECT ST_POINTFROMEWKT('SRID=4326;POINT(1 2)');
```

*Output*: `POINT(1 2)`

## ST_POINTFROMGEOJSON

Creates a `POINT` represented by the specified GeoJSON value as an input argument. A second optional `BOOLEAN` argument determines if the specified GeoJSON should be converted from a planar to a geodesic representation.

If you specify a NULL value for either argument, the function returns NULL.

### Syntax

```sql
ST_POINTFROMGEOJSON(geojson [, geodesic ] )
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo_json` | `STRING` | A string of a GeoJSON.<br>Valid GeoJSON formats follow IETF® **standards**, which you can generate using the **ST_ASGEOJSON** function.<br>If you specify an invalid GeoJSON, the behavior of the function is undefined. The function returns NULL if any argument is NULL. |
| `geodesic` | `BOOLEAN` | Optional.<br>If you set this argument to `TRUE`, the specified GeoJSON is converted from a planar to a geodesic representation. This does not affect POINT geospatial objects.<br>The default value is `FALSE`. |

### Examples

In this example, the function captures a `POINT` from an empty GeoJSON representation.

SQL

```
SELECT ST_POINTFROMGEOJSON('{"type":"Point","coordinates":[]}',false);
```

*Output*: `POINT EMPTY`

In this example, the function captures a `POINT` from a GeoJSON representation.

SQL

```
SELECT ST_POINTFROMGEOJSON('{"type":"Point","coordinates":[1,1]}',false);
```

*Output*: `POINT(1 1)`

## ST_POINTFROMGEOHASH

Creates a `POINT` represented by the specified geohash.

### Syntax

```
SQL

ST_POINTFROMGEOHASH(geohash)
```

| Argument | Data Type | Description |
|---|---|---|
| `geohash` | `STRING` | A string of a valid geohash.<br>Valid geohashes contain only the characters `0123456789bcdefghjkmnpqrstuvwxyz`.<br>If you specify an invalid geohash, the function throws an `INVALID_ARGUMENT` error. The function returns NULL if this argument is NULL. |

### Examples

```
SQL

SELECT ST_POINTFROMGEOHASH('c0w3hf1s70w3hf1s70w3');
```

*Output*: `POINT(-126.00000000000003 48.00000000000007)`

```
SQL

SELECT ST_POINTFROMGEOHASH('kzn21');
```

*Output*: `POINT(42.60498046875 -5.60302734375)`

# ST_POINTFROMTEXT

Alias for **ST_POINT(char)**.

# ST_POINTFROMWKB

Alias for **ST_POINT(binary)**.

# Related Links

### Geospatial Data Types

## Conversion Functions

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# Polygon Constructors

Construct polygon geometries in OcientGeo using ST_POLYGON and related functions to build closed spatial regions from coordinate rings and boundaries.

OcientGeo™ POLYGON constructors use geospatial data to create a POLYGON object.

## ST_FORCECCW

Creates a standardized polygon from an existing one. Ocient® defines standardized as the exterior being counterclockwise (CCW) and all holes being clockwise (CW) oriented.

### Syntax

```
SQL

ST_FORCECCW(polygon)
```

| Argument | Data Type | Description |
|---|---|---|
| `polygon` | `POLYGON` | A `POLYGON` to be converted on its exterior counterclockwise and clockwise for any interior holes. |

### Example

```
SQL

SELECT ST_FORCECCW(ST_POLYGON('POLYGON((0 0,0 1,1 1,1 0,0 0))'));
```

*Output*: `POLYGON((0 0,1 0,1 1,0 1,0 0))`

## ST_MAKEPOLYGON

Alias for **ST_POLYGON**.

## ST_POLYGON

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Creates a `POLYGON`.

## ST_POLYGON(geo)

Creates a `POLYGON` from the specified `POINT`, `POINT` array, `LINESTRING`, or `POLYGON` geography.

### Syntax

```
SQL

ST_POLYGON(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POLYGON` | A `POINT`, `POINT` array, `LINESTRING`, or `POLYGON` value to be converted to a `POLYGON` object. |

### Example

```
SQL

SELECT ST_POLYGON(
        ST_LINESTRING(
            ST_POINT [](
                ST_POINT(1, 2),
                ST_POINT(1, 3),
                ST_POINT(1, 4),
                ST_POINT(1, 2))));
```

*Output*: `POLYGON((1 2,1 3,1 4,1 2))`

## ST_POLYGON(char)

Alias for ST_MAKEPOLYGON(char).

Creates a `POLYGON` from the specified `CHAR` representing a `POLYGON` in WKT format.

### Syntax

```sql
ST_POLYGON(char)
```

| Argument | Data Type | Description |
|---|---|---|
| `char` | `CHAR` that represents a `POLYGON` in WKT format. | The `CHAR` argument must represent a `POLYGON` in WKT format. |

### Example

```sql
SELECT ST_POLYGON('POLYGON((1 2,1 3,1 4,1 2))');
```

*Output*: `POLYGON((1 2,1 3,1 4,1 2))`

## ST_POLYGON(binary)

Alias for ST_POLYGONFROMWKB(binary).

Creates a `POLYGON` from the specified `BINARY`. The `BINARY` value must represent a `POLYGON` in WKB format.

### Syntax

```sql
ST_POLYGON(binary)
```

| Argument | Data Type | Description |
|---|---|---|
| `binary` | `BINARY` that represents a `POLYGON` in WKB format. | A `BINARY` argument to be converted to a `POLYGON`. The `BINARY` value must represent a `POLYGON` in WKB format. |

### Example

```sql
SELECT ST_POLYGON(BINARY('0x0103000000010000000500000000000000000000000000000000000000C
```

*Output*: `POLYGON((0 0,0 1,1 1,1 0,0 0))`

## ST_POLYGON(outer_ring, inner_rings)

Alias for ST_MAKEPOLYGON(outerRing, innerRings).

Creates a `POLYGON` from the specified outer ring (that must be either a `POINT`, `POINT` array, or `LINESTRING`) and the array of interior rings (closed lines).

The interior of the `POLYGON` is on the left when traveling around the exterior ring. The interior of a hole is on the right when traveling around a hole.

### Syntax

```sql
ST_POLYGON(outer_ring, inner_rings)
```

| Argument | Data Type | Description |
|---|---|---|
| `outer_ring` | `POINT`, `POINT` array, or `LINESTRING` | A `POINT`, `POINT` array, or `LINESTRING` that represents the outer ring of the `POLYGON` object. |
| `inner_rings` | `ARRAY` of `POINT` arrays, or `ARRAY` of `LINESTRING` values | An `ARRAY` of `POINT` arrays or `LINESTRING` values that represents the inner rings or holes in the `POLYGON` object. |

### Example

```sql
SELECT ST_POLYGON(
        ST_LINESTRING(ST_POINT [](ST_POINT(1, 2))),
        ST_LINESTRING [](ST_LINESTRING(ST_POINT [](ST_POINT(1, 2)))));
```

*Output*: `POLYGON((1.000000 2.000000), (1.000000 2.000000))`

# ST_POLYGONFROMWKB

Alias for **ST_POLYGON(binary)**.

# ST_POLYGONFROMEWKT

Alias for the **ST_POLYGON** constructor.

Creates a `POLYGON` using an EWKT-formatted `CHAR` as an input argument.

### Syntax

SQL

```
ST_POLYGONFROMEWKT(char)
```

| Argument | Data Type | Description |
|---|---|---|
| `char` | `CHAR` | A string that includes an SRID value and an EWKT-formatted value that represents a `POLYGON`.<br>Separate the values in the string by a semicolon in this format:<br>`'SRID = value; polygon_value'`<br>The input string must include the `SRID = value;` component. However, the database ignores this component as all Ocient geography types are `SRID = 4326`. |

### Example

SQL

```
SELECT ST_POLYGONFROMEWKT('SRID=4326;POLYGON((1 2,1 3,1 4,1 2))');
```

*Output*: `POLYGON((1 2,1 3,1 4,1 2))`

# ST_POLYGONFROMGEOJSON

Creates a `POLYGON` represented by the specified GeoJSON value as an input argument.

### Syntax

```
SQL

ST_POLYGONFROMGEOJSON(geojson [, geodesic ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo_json` | `STRING` | A string of a GeoJSON.<br>Valid GeoJSON formats follow IETF® **standards**, which you can generate using the **ST_ASGEOJSON** function.<br>If you specify an invalid GeoJSON, the behavior of the function is undefined. The function returns NULL if any argument is a NULL value. |
| `geodesic` | `BOOLEAN` | Optional.<br>If you specify `geodesic` as `TRUE`, the function adds points to the resulting `POLYGON` such that it remains within 10 meters of the original planar polygon.<br>If you do not specify this argument, the value defaults to `FALSE`. |

### Examples

In this example, the function produces an empty `POLYGON` value from the GeoJSON representation.

```
SQL

SELECT ST_POLYGONFROMGEOJSON('{"type":"Polygon","coordinates":[]}',false);
```

*Output*: `POLYGON EMPTY`

In this example, the function produces a `POLYGON` value from the GeoJSON representation.

```sql
SELECT ST_POLYGONFROMGEOJSON(
        '{"type":"Polygon","coordinates":[[[1,1],[1,5],[5,5],[5,1]]]}',
        false);
```

*Output*: `POLYGON((1 1, 1 5, 5 5, 5 1))`

# ST_POLYGONFROMTEXT

Alias for **ST_POLYGON(char)**.

# ST_WHOLEEARTH

Returns the database internal representation of the whole earth polygon. The **ST_ENVELOPE** function returns this `POLYGON` value, with the envelope set as the entire earth.

GIS specifications do not describe a canonical polygon for the whole earth, but this value serves as the Ocient-canonical polygon. The whole earth polygon is also equivalent to `ST_POLYGON('POLYGON((0 0,0 0,0 0,0 0')))`, which can have a separate meaning in other GIS implementations.

### Syntax

```sql
ST_WHOLEEARTH()
```

### Example

```sql
SELECT ST_WHOLEEARTH();
```

*Output*: `POLYGON((0.0 0.0, 0.0 0.0, 0.0 0.0, 0.0 0.0))`

# Spatial Measurement

Reference for OcientGeo spatial measurement functions that compute distance, length, area, perimeter, and other quantities on points, lines, and polygons.

OcientGeo™ spatial measurement functions can perform basic calculations on geospatial data, such as measuring the distance between two POINT objects or the area of a POLYGON object.

## ST_AREA

Returns the area of the specified geospatial object in the specified unit of measurement.

### Syntax

```
SQL

ST_AREA(geo [, units] [, use_spheroid ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be measured in the specified measurement unit. |
| `units` | `STRING` | Optional.<br>Supported units are `'FEET'`, `'KILOMETERS'`, `'MILES'`, and `'METERS'`.<br>The default value is `'METERS'`. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this value to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

### Example

```sql
SELECT ST_AREA(
        ST_POLYGON(ST_LINESTRING('LINESTRING(2 3, 2 4, 4 2, 2 3)')),
        'MILES');
```

*Output*: `196932665.2369081`

# ST_ANGLE

Calculates the angle between two lines. The lines are represented by three `POINT` values, including one point for each line (a, b), and a third point (c) representing the vertex where they intersect. The function calculates the spherical angle as formed by the two great circles defined by (a, c) and (b, c).

ST_ANGLE returns the value in radians, in the range `[0, 2pi]`, excluding the value `2pi`.

If either a or b is the same or exactly antipodal to c, the function returns NULL. If any argument is NULL, the function returns NULL.

### Syntax

```sql
ST_ANGLE(endpoint_a, vertex_c, endpoint_b)
```

| Argument | Data Type | Description |
|---|---|---|
| `endpoint_a` | `POINT` | A `POINT` that represents an endpoint for a line between its position and the `vertex_c` value. |
| `vertex_c` | `POINT` | A `POINT` that represents the intersection between two lines. The lines comprise the endpoints between `endpoint_a` and `vertex_c`, and `endpoint_b` and `vertex_c`. |
| `endpoint_b` | `POINT` | A `POINT` that represents an endpoint for a line between its position and the `vertex_c` value. |

### Example

```sql
SELECT ST_ANGLE(ST_POINT(1,0), ST_POINT(0,0), ST_POINT(1,1));
```

*Output*: `5.49778714378213`

# ST_AZIMUTH

Returns the azimuth of the line from `point1` to `point2` in radians.

Returns NULL if either of the points are empty. Returns `0` if both of the points are the same.

### Syntax

```sql
ST_AZIMUTH(point1, point2)
```

| Argument | Data Type | Description |
|---|---|---|
| `point1` | `POINT` | An endpoint for a line to be calculated for its azimuth value. |
| `point2` | `POINT` | An endpoint for a line to be calculated for its azimuth value. |

### Example

```sql
SELECT ST_AZIMUTH(ST_POINT(1,1), ST_POINT(2,2));
```

*Output*: `0.785398163397448`

# ST_DISTANCE

Returns the minimum distance between the specified arguments.

The `ST_DISTANCE` function returns the minimum distance in the specified unit of measurement. The `use_spheroid` optional argument enables the computation to use a spheroid model rather than a spherical one.

### Syntax

SQL

```
ST_DISTANCE(geo1, geo2 [, units] [, use_spheroid] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be measured for its minimum distance to `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be measured for its minimum distance to `geo1`. |
| `units` | `STRING` | Optional.<br>Supported units include `'FEET'`, `'KILOMETERS'`, `'MILES'`, and `'METERS'`.<br>If you do not specify this argument, the value defaults to `'METERS'`. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this value to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

### Example

SQL

```
SELECT ST_DISTANCE(
        ST_LINESTRING('LINESTRING(2 3, 2 4)'),
        ST_LINESTRING('LINESTRING(1 2, 1 4, 1 5)'),
        'METERS',
        true);
```

*Output*: `111050.10339481`

To use ST_DISTANCE as a spatiotemporal function to calculate the minimum simultaneous distance between two linestring-timestamp array pairs, see the **ST_DISTANCE** function in **Spatiotemporal Measurement**.

# ST_DISTANCESPHERE

Returns the minimum distance between the specified arguments using a spherical computation.

This function is identical to ST_DISTANCE with the `use_spheroid` argument set to `FALSE`.

SQL

```
ST_DISTANCESPHERE(geo1, geo2 [, units] )
```

See **ST_DISTANCE** for usage example.

# ST_DISTANCESPHEROID

Returns the minimum distance between the specified arguments using a spheroid computation.

This function is identical to ST_DISTANCE with the `use_spheroid` argument set to `TRUE`.

SQL

```
ST_DISTANCESPHEROID(geo1, geo2 [, units] )
```

See **ST_DISTANCE** for usage example.

# ST_EUCLIDEANDISTANCE3D

Returns the minimum distance between two geospatial points with altitude values. The distance represents the length of a Euclidean line between the points.

**Syntax**

SQL

```
ST_EUCLIDEANDISTANCE3D(point1, altitude1, point2, altitude2 [, units] )
```

| Argument | Data Type | Description |
|---|---|---|
| `point1` | `POINT` | A geospatial point that represents a Euclidean line with `point2`. |
| `altitude1` | `DOUBLE` | Distance from the surface of the Earth for `point1`.<br>This argument uses meters, unless you specify a different unit of measurement with the `units` argument. |
| `point2` | `POINT` | A geospatial point that represents a Euclidean line with `point1`. |
| `altitude2` | `DOUBLE` | Distance from the surface of the Earth for `point2`.<br>This argument uses meters, unless you specify a different unit of measurement with the `units` argument. |
| `units` | `VARCHAR` | Optional.<br>This argument specifies the unit of measurement for the distance input arguments and the function output.<br>Supported units are `'FEET'`, `'KILOMETERS'`, `'MILES'`, and `'METERS'`.<br>The default value is `'METERS'`. |

### Example

SQL

```
SELECT ST_EUCLIDEANDISTANCE3D(
    ST_POINT(0,0),1000.0,
    ST_POINT(0,1),1000.0,
    'METERS');
```

*Output*: `111211.09372321835`

## ST_HAUSDORFFDISTANCE

Returns the Hausdorff distance between two geographies in a specified measurement. If any argument is NULL or empty, the function returns NULL.

The two geographies can be `POINT`, `LINESTRING`, or `POLYGON` values. The system promotes these geographies to filled polygons. Behavior is undefined if the resulting polygons are not convex.

### Syntax

```
SQL

ST_HAUSDORFFDISTANCE(geo1, geo2 [, units] [, use_spheroid] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be measured for its Hausdorff distance to `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be measured for its Hausdorff distance to `geo1`. |
| `units` | `STRING` | Optional.<br>Supported units are `'FEET'`, `'KILOMETERS'`, `'MILES'`, and `'METERS'`.<br>The default value is `'METERS'`. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this argument to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

### Example

```
SQL

SELECT ST_HAUSDORFFDISTANCE(
        ST_POLYGON('POLYGON((1 1, 2 2, 1 2, 1 1))'),
        ST_POLYGON('POLYGON((0 0, 2 1, 2 0, 0 0))'),
        'METERS',
        TRUE);
```

*Output*: `156899.5136831999`

# ST_LENGTH

Returns the length of the specified line in the specified measurement unit.

Returns `0` for all geography types except for `LINESTRING`. To return the total length of a `POLYGON`, use **ST_PERIMETER**.

### Syntax

SQL

```
ST_LENGTH(geo [, units] [, use_spheroid] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `LINESTRING` | A line that is to be measured for its length.<br>The function accepts `POINT` and `POLYGON` data types, but returns `0`. |
| `units` | `STRING` | Optional.<br>Supported units are `'FEET'`, `'KILOMETERS'`, `'MILES'`, and `'METERS'`.<br>The default value is `'METERS'`. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this argument to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

### Example

SQL

```
SELECT ST_LENGTH(
        ST_LINESTRING('LINESTRING(1 2, 1 4)'),
        'METERS',
        false);
```

*Output*: `222390.10395618092`

# ST_LENGTH2D

Alias for **ST_LENGTH**.

# ST_MINIMUMDISTANCETOSURFACE

Calculates the shortest distance between any point along a Euclidean line segment in three-dimensional space and the surface of the Earth. Two input points and their altitudes define this line segment. The line can go above or below the surface of the Earth.

The function takes the difference of both points from the center of the Earth to calculate the distance between the nearest point of the line and the surface of the Earth.

The function returns the distance in meters or another unit of measurement if specified. If the returned distance is positive, the shortest distance is above the surface. If the result is negative, the shortest distance is below the surface.

### Syntax

SQL

```
ST_MINIMUMDISTANCETOSURFACE(point1, altitude1, point2, altitude2 [, units] )
```

| Argument | Data Type | Description |
|---|---|---|
| `point1` | `POINT` | A geospatial point that represents a Euclidean line with `point2`. |
| `altitude1` | `DOUBLE` | Distance from the surface of the Earth for `point1`.<br>This argument uses meters, unless you specify a different unit of measurement with the `units` argument. |
| `point2` | `POINT` | A geospatial point that represents a Euclidean line with `point1`. |
| `altitude2` | `DOUBLE` | Distance from the surface of the Earth for `point2`.<br>This argument uses meters, unless you specify a different unit of measurement with the `units` argument. |
| `units` | `VARCHAR` | Optional.<br>This argument specifies the unit of measurement for the distance input arguments and the function output.<br>Supported units are `'FEET'`, `'KILOMETERS'`, `'MILES'`, and `'METERS'`.<br>The default value is `'METERS'`. |

### Examples

This example takes a line from two points and calculates the distance of the nearest point to the surface of the Earth.

SQL

```
SELECT ST_MINIMUMDISTANCETOSURFACE(
    ST_POINT(0,0),1000.0,
    ST_POINT(0,1),1000.0,
    'METERS');
```

*Output*: `757.3734914669767`

In this example, the output is negative, meaning the smallest distance is actually below the surface of the Earth.

SQL

```
SELECT ST_MINIMUMDISTANCETOSURFACE(
    ST_POINT(0,0),1000.0,
    ST_POINT(0,5),1000.0,
    'METERS');
```

*Output*: `-5064.738915202208`

# ST_MAXDISTANCE

Returns the maximum distance between the specified arguments.

ST_MAXDISTANCE returns the maximum distance in the specified unit of measurement. The `use_spheroid` optional argument enables the computation to use a spheroid model rather than a spherical one.

### Syntax

SQL

```
ST_MAXDISTANCE(geo1, geo2 [, units] [, use_spheroid] )
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be measured for its maximum distance to `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be measured for its maximum distance to `geo1`. |
| `units` | `STRING` | Optional.<br>Supported units are `'FEET'`, `'KILOMETERS'`, `'MILES'`, and `'METERS'`.<br>The default value is `'METERS'`. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this argument to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

### Example

SQL

```
SELECT ST_MAXDISTANCE(
        ST_POLYGON(ST_LINESTRING('LINESTRING(1 2, 1 4, 1 7, 1 2)')),
        ST_POLYGON(ST_LINESTRING('LINESTRING(1 2, 1 4, 1 5, 1 2)')),
        'METERS',
        false);
```

*Output*: `555975.2598904524`

> To use ST_MAXDISTANCE as a spatiotemporal function to calculate the maximum simultaneous distance between two linestring-timestamp array pairs, see the **ST_MAXDISTANCE** function in **Spatiotemporal Measurement**.

## ST_PERIMETER

Returns the length of the exterior (outer ring) of the `POLYGON` in the specified unit of measurement.

Returns `0` for all geography types except for `POLYGON`. To return the length of a `LINESTRING`, use **ST_LENGTH**.

### Syntax

```
SQL

ST_PERIMETER(geo, [, units] [, use_spheroid] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POLYGON` | A `POLYGON` that is to be measured for its total perimeter length.<br>The function accepts `POINT` and `LINESTRING` data types, but returns `0`. |
| `units` | `STRING` | Optional.<br>Supported units are `'FEET'`, `'KILOMETERS'`, `'MILES'`, and `'METERS'`.<br>The default value is `'METERS'`. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this argument to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

### Example

```
SQL

SELECT ST_PERIMETER(
        ST_POLYGON(ST_LINESTRING('LINESTRING(1 2, 1 3, 1 3, 1 2)')),
        'METERS',
        false);
```

*Output*: `222390.1039561809`

# ST_PERIMETER2D

Alias for **ST_PERIMETER**.

# Related Links

### Geospatial Data Types

## Spatial Operators

## Spatial Relationships

© 2026 Ocient All Rights Reserved Terms Of Use Privacy Statement

# Spatial Operators

Reference for OcientGeo spatial operators that perform geometric operations such as buffering, simplification, union, intersection, and difference.

OcientGeo™ spatial noperators perform geometry calculations on geospatial data to return a different type of geospatial data.

## ST_BOUNDINGDIAGONAL

Returns the diagonal `LINESTRING` from the minimum point to the maximum point of the bounding box that **ST_ENVELOPE** returns.

### Syntax

```sql
ST_BOUNDINGDIAGONAL(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be measured for the diagonal length of its bounding box. |

### Example

```sql
SELECT ST_BOUNDINGDIAGONAL(
        ST_POLYGON(ST_LINESTRING('LINESTRING(1 2, 1 3, 1 3, 1 2)'))
    );
```

*Output*: `LINESTRING(1 2,1 3)`

## ST_BUFFER

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Returns a geography that contains all points where the distance from the geography is less than or equal to the specified distance. The function simplifies the geometry before buffering unless you specify the `simplification_tolerance` argument with a zero or negative value.

The output of the function is an array of polygons. For POINT and LINESTRING data types, the returned array contains one polygon only.

### Syntax

SQL

```
ST_BUFFER(geo, radius [, num_segments_per_quarter_circle]
          [, simplification_tolerance] [, maximum_radius_error]
          [, join_style] [, miter_limit]
          [, endcap_style] [, side_style])
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object, specified as a point, linestring, or polygon, which the function buffers. |
| `radius` | `DOUBLE` | Radius, specified as a double, that indicates the distance to buffer the geospatial object in meters. Negative values cause polygons to shrink. Also, negative values cause the result to be empty for points and linestrings. |
| `num_segments_per_quarter_circle` | `BIGINT` | Optional.<br>The number of segments to use per quarter circle when parts of the buffer are round, specified as a BIGINT. Only use if the `join_style` or `endcap_style` value is set to `ROUND`.<br>Defaults to `8`. |
| `simplification_tolerance` | `DOUBLE` | Optional.<br>Value that the function passes to the ST_SIMPLIFYARRAY function prior to buffering.<br>If you specify a zero or negative value, the function skips simplification of the geometry.<br>The unit is meters.<br>Defaults to `500`. |
| `maximum_radius_error` | `DOUBLE` | Optional.<br>Maximum radius error, specified as a double. The returned buffer might be slightly larger than the |

| Argument | Data Type | Description |
|---|---|---|
| | | `radius` value by this amount. This value is required because arcs of great circles cannot be parallel. Use this argument for linestrings and polygons only.<br>Defaults to `10.0`. |
| `join_style` | `STRING` | Optional.<br>The type of join to use at the corners where segments of the geometry meet, specified as a string. Supported styles are `ROUND`, `BEVEL`, and `MITER`. Use this argument for linestrings and polygons only.<br>Defaults to `ROUND`. |
| `miter_limit` | `DOUBLE` | Optional.<br>Miter limit, specified as a double. Use this argument only if the `join_style` value is set to `MITER`. A mitered corner is cut off at a distance of `miter_ratio * radius` from the corner point of the geometry. Use this argument for linestrings and polygons only.<br>Defaults to `1.0`. |
| `endcap_style` | `STRING` | Optional.<br>The type of end cap for use at the ends of linestrings, specified as a string. Supported styles are `ROUND`, `SQUARE`, and `FLAT`. Use this argument for linestrings only.<br>Defaults to `ROUND`. |
| `side_style` | `STRING` | Optional.<br>The side, specified as a string, that denotes the side for buffering the geometry. Supported styles are `BOTH`, `LEFT`, and `RIGHT`. Use this argument for linestrings only.<br>Defaults to `BOTH`. |

## Example

SQL

```
SELECT ST_BUFFER(
        ST_POLYGON('POLYGON((0 0, 1 0, 1 1, 0 0))'), 2000, 8, 500.0, 10.0,
        'MITER', 2.0);
```

*Output*:

`[POLYGON((2.202700241764562E-18 -0.017986411844962975, 1.0179863625702694 -0.0179863616840571, 1.0179892379654352 1.031486286416526, 1.009550207729886`

`1.0349816974070565, -0.03498171178141835 -0.009548649645081482, -0.03148633724650228 -0.01798632287046757, 2.202700241764562E-18 -0.017986411844962975))]`

# ST_CLOSESTPOINT

Returns the two-dimensional `POINT` of one specified geospatial object that is closest to a second specified geospatial object. This function works with any geospatial type.

If either geospatial argument is empty, the function returns NULL.

### Syntax

SQL

```
ST_CLOSESTPOINT(geo1, geo2 [, use_spheroid] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be computed to determine its closest `POINT` value relative to `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A second geospatial object to be compared to `geo1` to find the closest `POINT` value of `geo1`. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this value to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

### Example

SQL

```
SELECT ST_CLOSESTPOINT(
        ST_POLYGON(ST_LINESTRING('LINESTRING(2 3, 2 4, 2 4, 2 3)')),
        ST_POLYGON(ST_LINESTRING('LINESTRING(1 2, 1 4, 1 5, 1 2)')));
```

*Output*: `POINT(2,3)`

# ST_CONVEXHULL

Returns a `POLYGON` representing the convex hull of the input geometry.

The convex hull is the smallest convex geometry that encloses the input geometry. If the `geo` argument is empty, the function returns an empty `POLYGON`.

### Syntax

```
SQL

ST_CONVEXHULL(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be computed for a `POLYGON` of its convex hull.<br>If `geo` is a `POINT` or a single-point `LINESTRING` or `POLYGON`, the function returns a `POLYGON` containing only that point value.<br>If `geo` is NULL, the function returns NULL. |

### Example

```
SQL

SELECT ST_CONVEXHULL(
        ST_POLYGON('POLYGON((0 0,1 0,1 1,0.5 0.5,0.3 0.3,0 1,0 0))'));
```

*Output*: `POLYGON((0.0 0.0, 1.0 0.0, 1.0 1.0, 0.0 1.0, 0.0 0.0))`

## ST_DIFFERENCEARRAY

Returns an array containing any geospatial objects that are present in the first specified geospatial argument that are not found in the second geospatial argument.

### Syntax

```
SQL

ST_DIFFERENCEARRAY(geo1, geo2)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2` to find any unique geospatial values. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A second geospatial object used to compare with `geo1` to find unique values.<br>The function captures only objects that are unique to `geo1`, and not those unique to `geo2`. |

### Example

In this example, the function returns `LINESTRING(2.0 2.0, 3.0 3.0)` because that portion of the first `LINESTRING` argument is not present in the second argument.

SQL

```
SELECT ST_DIFFERENCEARRAY(
        ST_LINESTRING('LINESTRING(1 1, 2 2, 3 3)'),
        ST_LINESTRING('LINESTRING(1 1, 2 2)'));
```

*Output*: `[LINESTRING(2.0 2.0, 3.0 3.0)]`

## ST_ENVELOPE

Returns a `POLYGON` that represents the minimum bounding box for the specified geography. If the specified argument is empty, the function returns an empty `POLYGON`.

A single `POINT` argument results in a single `POINT`.

### Syntax

SQL

```
ST_ENVELOPE(geo)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be computed for the vertices of its bounding box. |

### Example

```sql
SELECT ST_ENVELOPE(
        ST_POLYGON(ST_LINESTRING('LINESTRING(10 10, 0 0)')));
```

*Output*: `POLYGON((0 0,10 0,10 10,0 10,0 0))`

## ST_EXPAND

Returns the bounding box of a specified geospatial value, which is expanded by a specified length. The unit of length is in meters.

### Syntax

```sql
ST_EXPAND(geo1, units_to_expand)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be computed for the vertices of its bounding box, with the added `units_to_expand`. |
| `units_to_expand` | `DOUBLE` | An additional distance to expand the bounding box of `geo`.<br>Specify this argument only in meters. |

### Example

```sql
ST_EXPAND(ST_POLYGON('POLYGON((1 1, 2 1, 2 2, 1 1))'), 1.0);
```

*Output*: `POLYGON((0.99 0.99, 1.33 0.99, 1.66 0.99, 2.01 0.99, 2.00 2.00, 1.66 2.00, 1.33 2.00, 0.99 2.00, 0.99 0.99))`

# ST_EXTERIORRING

Returns a `LINESTRING` that represents the exterior ring of a provided `POLYGON` value. If you specify a geography value that is not a `POLYGON`, the function returns NULL.

### Syntax

```
SQL

ST_EXTERIORRING(polygon)
```

| Argument | Data Type | Description |
|---|---|---|
| `polygon` | `POLYGON` | A `POLYGON` object to be computed for a `LINESTRING` of its perimeter. |

### Example

```
SQL

SELECT ST_EXTERIORRING(ST_POLYGON('POLYGON((1 1, 3 1, 2 2, 1 1))'));
```

*Output*: `LINESTRING(1.0 1.0, 3.0 1.0, 2.0 2.0, 1.0 1.0)`

# ST_FLIPCOORDINATES

Returns a new geographic object with the X and Y coordinates switched using the specified argument. The return type is the same as the specified type.

### Syntax

```
SQL

ST_FLIPCOORDINATES(geo)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geographic object for switching its X and Y coordinates. |

### Example

```
SQL

ST_FLIPCOORDINATES(ST_POINT('POINT(1 3)'));
```

*Output*: `POINT(3.0 1.0)`

## ST_FORCE2D

Convert a geographic object into a two-dimensional geography. The output representations only have the X and Y coordinates.

The returned type is the same as the specified type.

### Syntax

```
SQL

ST_FORCE2D(geo1)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geographic object to be converted to a two-dimensional object. |

### Example

```
SQL

SELECT ST_FORCE2D(ST_POINT('POINT(1 1)'));
```

*Output*: `POINT(1.0 1.0)`

# ST_INTERIORRINGN

Returns a `LINESTRING` representing the interior ring of the specified `POLYGON`, which is specified by its index. (1-indexed)

Returns NULL if the index is out of range, or if you specify a non-POLYGON geography.

### Syntax

SQL

```
ST_INTERIORRINGN(polygon, index)
```

| Argument | Data Type | Description |
|---|---|---|
| `polygon` | `POLYGON` | A `POLYGON` object to be computed for its interior ring. |
| `index` | `INTEGER` | An index that represents the specific interior ring of the `polygon` value to be captured.<br>Interior-ring indexes are 1-based, meaning the first object has an index of `1`. |

### Example

SQL

```
SELECT ST_INTERIORRINGN(
        ST_POLYGON(
            ST_LINESTRING(ST_POINT [](ST_POINT(1, 2))),
            ST_LINESTRING [](ST_LINESTRING(ST_POINT [](ST_POINT(1, 2))))),
        1);
```

*Output*: `LINESTRING(1 2)`

# ST_INTERSECTALL

Returns the intersection of all geographies in the specified array. All geographies in the array must be the same type. The ST_INTERSECTALL function ignores NULL values in the array. The output geography has the same type as the input geometries.

### Syntax

```
SQL

ST_INTERSECTALL(array)
```

| Argument | Data Type | Description |
|---|---|---|
| `array` | `ARRAY` of `POINT`, `LINESTRING`, or `POLYGON` | An array of geographic objects, which all must be the same type. |

### Example

```
SQL

SELECT ST_INTERSECTALL(
        ST_POINT [](ST_POINT(0, 0), ST_POINT(1, 1), ST_POINT(2, 2)));
```

*Output*: `POINT[]`

## ST_INTERSECTIONARRAY

Returns a geography that represents the point-set intersection of two geographies.

If the two geographies are of different types, the function returns an array of the smallest geography. For example, if `geo1` is a `POINT`, and `geo2` is a `POLYGON`, the function returns an array of `POINT` values.

### Syntax

```
SQL

ST_INTERSECTIONARRAY(geo1, geo2)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geographic object to be compared to `geo2` to find a set of intersections. |

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geographic object to be compared to `geo1` to find a set of intersections. |

### Example

This example compares two polygons to find any intersections. Because both objects are `POLYGON` types, the result is also a `POLYGON` containing all intersection points.

SQL

```
SELECT ST_INTERSECTIONARRAY(
    ST_POLYGON(ST_LINESTRING(ST_POINT(1,2),ST_POINT(3,4))),
    ST_POLYGON(ST_LINESTRING(ST_POINT(1,2),ST_POINT(4,5))));
```

*Output*: `[POLYGON((1, 2))]`

## ST_LONGESTLINE

Returns the longest `LINESTRING` between two specified geospatial arguments.

### Syntax

SQL

```
ST_LONGESTLINE(geo1, geo2, use_spheroid)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for the determination of the longest `LINESTRING` relative to `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for the determination of the longest `LINESTRING` relative to `geo1`. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this value to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### Example

```sql
SELECT ST_LONGESTLINE(
    ST_MAKELINE('LINESTRING(0 3, 1 3)'),
    ST_MAKELINE('LINESTRING(2 3, 0 3)'));
```

*Output*: `LINESTRING(0.0 3.0, 2.0 3.0)`

> To use ST_LONGESTLINE as a spatiotemporal function to calculate the longest line between two points at a concurrent time, see the **ST_LONGESTLINE** function.

## ST_MAKEENVELOPE

Alias for `ST_ENVELOPE(ST_LINESTRING(ST_POINT(xmin, ymin), ST_POINT(xmax, ymax)))`.

Returns a `POLYGON` with vertices representing the minimum bounding box for the specified coordinates.

### Syntax

```sql
ST_MAKEENVELOPE(xmin, ymin, xmax, ymax)
```

| Argument | Data Type | Description |
|---|---|---|
| `xmin` | `DOUBLE` | The minimum x value for the bounding box. |
| `ymin` | `DOUBLE` | The minimum y value for the bounding box. |
| `xmax` | `DOUBLE` | The maximum x value for the bounding box. |
| `ymax` | `DOUBLE` | The maximum y value for the bounding box. |

### Example

```sql
SELECT ST_MAKEENVELOPE(0, 0, 10, 10);
```

*Output*: `POLYGON((0.0 0.0, 10.0 0.0, 10.0 10.0, 0.0 10.0, 0.0 0.0))`

# ST_MINIMUMBOUNDINGCIRCLE

Returns the smallest circle `POLYGON` that contains the specified geographic object.

The function requires an additional argument to define the number of segments for inclusion in each quarter of the returned circle.

### Syntax

```sql
ST_MINIMUMBOUNDINGCIRCLE(geo, num_segs_per_qt_circ)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for the determination of the smallest possible circle `POLYGON` to encompass it. |
| `num_segs_per_qt_circ` | `INTEGER` | The number of segments to be included in each quarter of the returned circle `POLYGON`. |

### Example

```sql
SELECT ST_MINIMUMBOUNDINGCIRCLE(ST_POLYGON('POLYGON((1 1, 2 1, 2 2, 1 1))'), 3);
```

*Output*: `POLYGON((1.49 2.91, 0.27 0.79, 2.72 0.79, 1.49 2.91))`

# ST_MULTIDIFFERENCEARRAY

Returns an array of geographies representing the parts of the union of the geographies in the first array that do not intersect with the union of geographies in the second array.

This operation is not symmetric, meaning `ST_MULTIDIFFERENCEARRAY(array1, array2)` does not produce the same results as `ST_MULTIDIFFERENCEARRAY(array2, array1)` unless both arrays are identical.

The function ignores NULL types. For types besides NULL, all geographies in both arrays must be of the same type.

The output geographies are the same type as the input geographies.

### Syntax

SQL

```
ST_MULTIDIFFERENCEARRAY(array1, array2)
```

| Argument | Data Type | Description |
|---|---|---|
| `array1` | `ARRAY` of `POINT`, `LINESTRING`, or `POLYGON` values. | An array of geographic objects to be compared to the geographic objects in `array2`.<br>The function returns any values in this array that do not intersect with `array2`. |
| `array2` | `ARRAY` of `POINT`, `LINESTRING`, or `POLYGON` values. | An array of geographic objects to be compared to the geographic objects in `array1`.<br>The function returns only values that do not intersect in `array1`. |

### Example

SQL

```
ST_MULTIDIFFERENCEARRAY(
    POINT[](ST_POINT(0, 0), ST_POINT(1, 1)),
    POINT[](ST_POINT(1, 1), ST_POINT(2, 2)));
```

*Output*: `['POINT(0.0 0.0)']`

# ST_MULTIINTERSECTIONARRAY

When you specify two arrays of geospatial objects, this function returns an array of any intersections. The function treats each specified array as a union of all its geospatial values.

All geographies in both arrays must be of the same type, not counting NULL values, which the function ignores.

The output geographies are the same type as the input geographies.

### Syntax

SQL

```
ST_MULTIINTERSECTIONARRAY(array1, array2)
```

| Argument | Data Type | Description |
|---|---|---|
| `array1` | `ARRAY` of `POINT`, `LINESTRING`, or `POLYGON` values. | An array of geographic objects to be compared to the geographic objects in `array2` for any intersections.<br>The data types in this array must match the data types in `array2` unless they are NULL. |
| `array2` | `ARRAY` of `POINT`, `LINESTRING`, or `POLYGON` values. | An array of geographic objects to be compared to the geographic objects in `array1` for any intersections.<br>The data types in this array must match the data types in `array1` unless they are NULL. |

### Example

SQL

```
SELECT ST_MULTIINTERSECTIONARRAY(
    POINT[](ST_POINT(0, 0), ST_POINT(1, 1)),
    POINT[](ST_POINT(1, 1), ST_POINT(2, 2)));
```

*Output*: `['POINT(1.0 1.0)']`

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

# ST_MULTISYMDIFFERENCEARRAY

Alias for `ST_MULTIUNIONARRAY(array1, array2) - ST_MULTIINTERSECTIONARRAY(array1, array2)`.

When you specify two arrays of geospatial objects, this function returns an array of any geospatial values that do not intersect. The function treats each specified array as a union of all its geospatial values.

All geographies in both arrays must be of the same type, not counting NULL values, which the function ignores.

The output geographies are the same type as the input geographies.

### Syntax

SQL

```
ST_MULTISYMDIFFERENCEARRAY(array1, array2)
```

| Argument | Data Type | Description |
|---|---|---|
| `array1` | `ARRAY` of `POINT`, `LINESTRING`, or `POLYGON` values. | An array of geographic objects to be compared to the geographic objects in `array2` for any values that do not intersect.<br>The data types in this array must match the data types in `array2` unless they are NULL. |
| `array2` | `ARRAY` of `POINT`, `LINESTRING`, or `POLYGON` values. | An array of geographic objects to be compared to the geographic objects in `array1` for any values that do not intersect.<br>The data types in this array must match the data types in `array1` unless they are NULL. |

### Example

SQL

```
SELECT ST_MULTISYMDIFFERENCEARRAY(
    POINT[](ST_POINT(0, 0), ST_POINT(1, 1)),
    POINT[](ST_POINT(1, 1), ST_POINT(2, 2)));
```

*Output*: `['POINT(0.0 0.0)','POINT(2.0 2.0)']`

# ST_MULTIUNIONARRAY

When you specify two arrays of geospatial objects, this function returns one array that represents a union of all geographies in both arrays.

All geographies in both arrays must be the same type. The function ignores NULL values in the arrays. The output geographies are the same type as the input geographies.

### Syntax

SQL

```
ST_MULTIUNIONARRAY(array1, array2)
```

| Argument | Data Type | Description |
|---|---|---|
| `array1` | `ARRAY` of `POINT`, `LINESTRING`, or `POLYGON` values. | An array of geographic objects to be combined with `array2`.<br>The data types in this array must match the data types in `array2` unless they are NULL. |
| `array2` | `ARRAY` of `POINT`, `LINESTRING`, or `POLYGON` values. | An array of geographic objects to be combined with `array1`.<br>The data types in this array must match the data types in `array1` unless they are NULL. |

### Example

SQL

```
SELECT ST_MULTIUNIONARRAY(
    POINT[](ST_POINT(0, 0), ST_POINT(1, 1)),
    POINT[](ST_POINT(1, 1), ST_POINT(2, 2)));
```

*Output*: `['POINT(1.0 1.0)','POINT(2.0 2.0)','POINT(0.0 0.0)']`

# ST_NRINGS

Returns the number of rings of the specified `POLYGON`, including both interior and exterior rings. If you specify a geography object that is not a `POLYGON`, this function returns `0`.

### Syntax

```
SQL

ST_NRINGS(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POLYGON` | An object to be computed to return its total number of rings. |

### Example

```
SQL

SELECT ST_NRINGS(
        ST_POLYGON('POLYGON((1.0 2.0, 1.0 4.0, 1.0 5.0, 1.0 2.0))'));
```

*Output*: `1`

## ST_NUMINTERIORRINGS or ST_NUMINTERIORRING

Returns the number of interior rings of the specified `POLYGON`. If you specify a geography object that is not a `POLYGON`, this function returns `0`.

### Syntax

```
SQL

ST_NUMINTERIORRINGS(polygon)
```

```
SQL

ST_NUMINTERIORRING(polygon)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `polygon` | `POLYGON` | An object to be computed to return its total number of interior rings. |

### Example

SQL

```
SELECT ST_NUMINTERIORRINGS(
        ST_POLYGON(
            ST_LINESTRING(ST_POINT [](ST_POINT(1, 2))),
            ST_LINESTRING [](ST_LINESTRING(ST_POINT [](ST_POINT(1, 2))))));
```

*Output*: `1`

## ST_POINTONSURFACE

Returns a `POINT` guaranteed to intersect the specified geospatial object.

### Syntax

SQL

```
ST_POINTONSURFACE(geo1)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | An object to be computed for an intersection `POINT` value. |

### Example

SQL

```
SELECT ST_POINTONSURFACE(ST_POLYGON('POLYGON((1 1, 2 1, 2 2, 1 1))'));
```

*Output*: `POINT(1.0 1.0)`

# ST_PROJECT

Returns a `POINT` by projecting a distance and an azimuth value from the specified starting `POINT` value. The distance must be in meters, and azimuth must be in radians.

### Syntax

```
SQL

ST_PROJECT(point, distance, azimuth)
```

| Argument | Data Type | Description |
|---|---|---|
| `point` | `POINT` | A starting point for locating a returned destination by using the `distance` and `azimuth` values. |
| `distance` | `DOUBLE` | A distance value in meters. |
| `azimuth` | `DOUBLE` | An azimuth value in radians. |

### Example

```
SQL

SELECT ST_PROJECT(ST_POINT(1, 3), 100, 100);
```

*Output*: `POINT(0.99 3.00)`

# ST_REDUCEPRECISION

Returns a new geospatial object with all `POINT` values rounded to the specified decimal precision.

### Syntax

```
SQL

ST_REDUCEPRECISION(geo, precision)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be rounded to the specified `precision` value. |
| `precision` | `DOUBLE` | A decimal value that defines the level of precision for returned values.<br>For example, a precision of `0.01` returns values rounded to the hundredth decimal.<br>Do not use digits other than `0` and `1` to represent the precision. |

### Example

```sql
SELECT ST_REDUCEPRECISION(ST_POINT('POINT(1.21 1.34)'), 0.1);
```

*Output*:** `POINT(1.2 1.3)`

## ST_REMOVEREPEATEDPOINTS

Returns a new geospatial object with no repeated `POINT` values. The returned type is the same as the specified type.

### Syntax

```sql
ST_REMOVEREPEATEDPOINTS(geo)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for the removal of any duplicate `POINT` values. |

### Example

```sql
SELECT ST_REMOVEREPEATEDPOINTS(ST_LINESTRING('LINESTRING(1 2, 1 2, 2 1, 1 0)'));
```

*Output*: `LINESTRING(1.0 2.0, 2.0 1.0, 1.0 0.0)`

# ST_REVERSE

Returns a new geospatial object with the vertexes reversed. The returned type is the same as the specified type.

### Syntax

```sql
ST_REVERSE(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for vertex reversal. |

### Example

```sql
SELECT ST_REVERSE(ST_LINESTRING('LINESTRING(1 2,1 10)'));
```

*Output*: `LINESTRING(1.0 10.0, 1.0 2.0)`

# ST_SEGMENTIZE

Returns a geospatial object that the function modifies to have no segment longer than the specified `max_segment_length` in meters.

### Syntax

```
SQL

ST_SEGMENTIZE(geo, max_segment_length)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for segment modification. |
| `max_segment_length` | `DOUBLE` | The maximum length of a segment to modify the specified `geo` object. This value must be in METERS. |

### Example

```
SQL

SELECT ST_SEGMENTIZE(
        ST_POLYGON('POLYGON((1 1, 2 1, 2 2, 1 1))'),
        150000.0);
```

*Output*: `POLYGON((1.0 1.0, 2.0 1.0, 2.0 2.0, 1.49 1.50, 1.0 1.0))`

## ST_SHORTESTLINE

Returns the shortest `LINESTRING` between two specified geospatial arguments.

### Syntax

```
SQL

ST_SHORTESTLINE(geo1, geo2, use_spheroid)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for the determination of the shortest `LINESTRING` relative to `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for the determination of the shortest `LINESTRING` relative to `geo1`. |

| Argument | Data Type | Description |
| --- | --- | --- |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this argument to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

### Example

SQL

```
SELECT ST_SHORTESTLINE(
    ST_MAKELINE('LINESTRING(4 3, 10 3)'),
    ST_MAKELINE('LINESTRING(0 1, 0 3)'));
```

*Output*: `LINESTRING(0.0 3.0, 4.0 3.0)`

> To use ST_SHORTESTLINE as a spatiotemporal operator to calculate the shortest line between two points at a concurrent time, see the **ST_SHORTESTLINE** function in the Spatiotemporal section.

## ST_SIMPLIFY

Returns a simplified version of the specified geography, which is either a `POINT` or `LINESTRING`.

The function simplifies the input geography by replacing nearly straight edges that contain multiple points with a single straight edge. The input geography does not change by more than the specified tolerance, which you specify as a `DOUBLE` in meters.

### Syntax

SQL

```
ST_SIMPLIFY(geo, tolerance)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT` or `LINESTRING` | A geospatial object to be simplified. |

| Argument | Data Type | Description |
| --- | --- | --- |
| `tolerance` | `DOUBLE` | A value that represents the maximum number of meters to simplify in the specified geography. |

### Example

SQL

```
SELECT ST_SIMPLIFY(
    ST_LINESTRING('LINESTRING(0 0, 0.05 0, 0.1 0, 0.15 0, 2 0)'), 1);
```

*Output*: `LINESTRING(0 0, 2 0)`

## ST_SIMPLIFYARRAY

Returns a `POLYGON` array that represents a simplified version of the specified geography, which is either a `POINT`, `LINESTRING`, or `POLYGON`.

The function simplifies the input geography by replacing nearly straight edges that contain multiple points with a single straight edge. The input geography does not change by more than the specified tolerance, which you specify as a `DOUBLE` in meters.

### Syntax

SQL

```
ST_SIMPLIFYARRAY(geo, tolerance)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be simplified. |
| `tolerance` | `DOUBLE` | A value that represents the maximum number of meters to simplify in the specified geography. |

### Example

In this example, ST_SIMPLIFYARRAY evaluates a `POLYGON` with an outer ring of 13 points and an inner ring with four points. The example sets a tolerance argument of 10,000 meters, meaning that is the maximum distance that the function simplifies.

SQL

```
SELECT ST_SIMPLIFYARRAY(
        ST_POLYGON(
            'POLYGON((0 0, 1 0, 1 0.49, 1.01 0.49, 1.01 0.51, 1 0.51, 1 1, 0 1, 0 0
            ),
        10000);
```

*Output*: `[POLYGON((0.0 0.5000000762285838, 1.0 0.500000076228584, 1.0 1.0, 0.0 1.0, 0.0 0.5000000762285838)), POLYGON((1.0 0.4998004375649452, 0.5 0.4, 0.0 0.4998004375649452, 0.0 0.0, 1.0 0.0, 1.0 0.4998004375649452))]`

As shown in the output, the ST_SIMPLIFYARRAY function has reduced the size of the outer `POLYGON` from 13 points to 5.

Note that the function actually increases the number of points in the inner ring, going from four to six. The increase is due to how close the inner ring is to the edges of the outer ring. Taken altogether, the function still reduced the total number of points in the `POLYGON`.

# ST_SNAPTOGRID

Returns a new geography value with all `POINT` values rounded to the specified precision. This function is similar to **ST_REDUCEPRECISION** but it allows you to specify the precision for the x and y coordinates separately.

### Syntax

SQL

```
ST_SNAPTOGRID(geo1, precision_x, precision_y)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be rounded to the specified precision values. |
| `precision_x` | `DOUBLE` | A decimal value representing the level of precision for the x value.<br>For example, a precision of `0.01` returns values rounded to the hundredth decimal.<br>Do not use digits other than `0` and `1` to represent the precision. |
| `precision_y` | `DOUBLE` | A decimal value representing the level of precision for the y value.<br>For example, a precision of `0.1` returns values rounded to the tenth decimal.<br>Do not use digits other than `0` and `1` to represent the precision. |

### Example

SQL

```
SELECT ST_SNAPTOGRID(
    ST_MAKEPOINT(1.1, 3.11), 1, 0.1);
```

*Output*: `POINT(1.0 3.1)`

## ST_SYMDIFFERENCEARRAY

Returns a geographic array that contains the parts that are not common between two geographic objects, `geo1` and `geo2`.

### Syntax

SQL

```
ST_SYMDIFFERENCEARRAY(geo1, geo2)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geographic object to be compared to the geographic objects in `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geographic object to be compared to the geographic objects in `geo1`. |

### Example

SQL

```
SELECT ST_SYMDIFFERENCEARRAY(
    ST_LINESTRING('LINESTRING(1 1, 2 2)'),
    ST_LINESTRING('LINESTRING(1 1, 2 2, 3 3)'));
```

*Output*: `[LINESTRING(2.0 2.0, 3.0 3.0)]`

## ST_UNIONARRAY

Performs a union of the input geography values to produce a geographic array.

### Syntax

SQL

```
ST_UNIONARRAY(geo1, geo2)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geographic object to be unified with the geographic values in `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geographic object to be unified with the geographic values in `geo1`. |

### Example

SQL

```
SELECT ST_UNIONARRAY(
    ST_LINESTRING('LINESTRING(0 0, 1 1, 2 2)'),
    ST_LINESTRING('LINESTRING(1 1, 2 2, 3 3)'));
```

*Output*: `['LINESTRING(0.0 0.0, 1.0 1.0, 2.0 2.0, 3.0 3.0)']`

# Spatial Relationships

Reference for OcientGeo spatial relationship functions including ST_INTERSECTS, ST_CONTAINS, ST_WITHIN, and other predicates for spatial joins and filtering.

OcientGeo™ spatial relationship functions use arguments to test for different types of spatial relationships.

## ST_CLUSTERDBSCAN

Returns the cluster number for each input geography based on a two-dimensional implementation of the density-based spatial clustering of applications with noise (**DBSCAN**) algorithm.

This function is a window function because the resulting value for an individual row depends on other rows and not just itself. No frame specification is allowed.

This function supports sort orders, but it is unnecessary unless deterministic resolution of tie-breaking in cluster determination is required. This tie-breaking happens only in situations where a point on the boundary of a cluster is equally valid for multiple clusters. In these cases, the result depends on the sort order of the data. For this reason, you might want to sort the data to force the deterministic behavior by using an `ORDER BY` in the `OVER` clause.

The function returns NULL for any row not included in a cluster.

### Syntax

SQL

```
ST_CLUSTERDBSCAN(geo, eps, min_neighbors)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be grouped into a cluster based on the DBSCAN algorithm. |

© 2026 Ocient, Inc

| Argument | Data Type | Description |
| --- | --- | --- |
| `eps` | `DOUBLE` | A numeric argument that controls the separation between objects before they are considered a new cluster.<br>The `eps` argument is in meters. |
| `min_neighbors` | `BIGINT` | The minimum number of objects within the appropriate distance of each other that need to exist before it is considered a cluster. |

### Example

SQL

```
SELECT ST_CLUSTERDBSCAN(ST_POINT(1.5, 1.5), 1.0, 1) OVER();
```

*Output*: `1`

## ST_CONTAINS

Returns `TRUE` if the first geographic argument, `geo1`, contains the second geographic argument, `geo2`.

`geo1` contains `geo2` only if all of these criteria are met:

- No `POINT` values of `geo2` are located at the exterior of `geo1`.
- At least one `POINT` in the interior of `geo2` lies in the interior of `geo1`.

Geographies do not contain their boundaries, therefore, all `POINT` values in a `LINESTRING` are interior, except for the endpoints, which are regarded as exterior boundaries.

If either `geo1` or `geo2` is NULL, then the function returns NULL.

### Syntax

SQL

```
SELECT ST_CONTAINS(geo1, geo2)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2`. The `POINT` values in `geo1` are evaluated to determine if they are contained within `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo1`. The `POINT` values in `geo2` are evaluated to determine if they are contained within `geo1`. |

### Example

SQL

```
SELECT ST_CONTAINS(
    ST_LINEFROMTEXT('LINESTRING(0 0, 1 1, 2 2)'),
    ST_POINT(1, 1));
```

*Output*: `true`

## ST_CONTAINSPROPERLY

This function is similar to ST_CONTAINS, but it has stricter criteria.

Returns true if `geo2` lies entirely in the interior of `geo1` and does not intersect or touch the boundary or exterior points.

Returns NULL if either `geo1` or `geo2` is NULL.

### Syntax

SQL

```
ST_CONTAINSPROPERLY(geo1, geo2)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2`. The `POINT` values in `geo1` are evaluated to determine if they are contained within `geo2`. |

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo1`. The `POINT` values in `geo2` are evaluated to determine if they are contained within `geo1`. |

### Examples

In this example, the first geographic object is a `POLYGON` representing a simple square (0 0, 1 0, 1 1, 0 1). The second geographic object is a small `LINESTRING` that spans from the point (0.25 0.25) to the point (0.75 0.75).

Because the line is located entirely within the polygon, never touching its boundaries, the function evaluates to `true`.

SQL

```
SELECT ST_CONTAINSPROPERLY(
        ST_MAKEPOLYGON(
            ST_MAKELINE(
                ARRAY [ST_POINT(0, 0), ST_POINT(1, 0), ST_POINT(1, 1), ST_POINT(0,
        ST_MAKELINE(ST_POINT(0.25, 0.25), ST_POINT(0.75, 0.75)));
```

*Output*: `TRUE`

The second geographic object is slightly altered in this example, where the line spans from (0 0) to (1 1). Both of these endpoints touch the boundaries of the polygon, so the function now evaluates to `false`.

SQL

```
SELECT ST_CONTAINSPROPERLY(
        ST_MAKEPOLYGON(
            ST_MAKELINE(
                ARRAY [ST_POINT(0, 0), ST_POINT(1, 0), ST_POINT(1, 1), ST_POINT(0,
        ST_MAKELINE(ST_POINT(0, 0), ST_POINT(1, 1)));
```

*Output*: `FALSE`

## ST_COVERS

Returns `TRUE` if no `POINT` in `geo2` is outside of `geo1`.

Returns NULL if either `geo1` or `geo2` is NULL.

### Syntax

```
SQL

ST_COVERS(geo1, geo2)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2`. The `POINT` values in `geo2` are evaluated to determine if they are contained within `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo1`. The `POINT` values in `geo2` are evaluated to determine if they are contained within `geo1`. |

### Example

```
SQL

SELECT ST_COVERS(
        ST_MAKEPOLYGON(
            ST_MAKELINE(
                ARRAY [ST_POINT(0, 0), ST_POINT(1, 0), ST_POINT(1, 1), ST_POINT(0,
        ST_MAKELINE(ST_POINT(0, 0), ST_POINT(1, 1)));
```

*Output*: `TRUE`

## ST_COVEREDBY

This function operates similarly to ST_COVERS, except the arguments are interchanged.

Returns `TRUE` if no `POINT` in `geo1` is outside of `geo2`.

Returns NULL if either `geo1` or `geo2` is NULL.

### Syntax

```sql
ST_COVEREDBY(geo1, geo2)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2`. The `POINT` values in `geo1` are evaluated to determine if they are contained within `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo1` The `POINT` values in `geo1` are evaluated to determine if they are contained within `geo2`. |

### Example

```sql
SELECT ST_COVEREDBY(
    ST_POINT(1,1),
    ST_POLYGON('POLYGON((1 1, 2 1, 2 2, 1 1))'));
```

*Output*: `TRUE`

## ST_CROSSES

Returns `TRUE` if two geospatial objects meet this criteria:

- The intersection of the geospatial interiors is not empty.
- The intersection is not equal to `geo1` or `geo2`.
- Neither geospatial object is a single `POINT`.

Returns NULL if either argument is NULL.

### Syntax

```sql
ST_CROSSES(geo1, geo2)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2` to evaluate whether they cross. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo1` to evaluate whether they cross. |

### Example

SQL

```
SELECT ST_CROSSES(
    ST_LINESTRING(ST_POINT(0,0), ST_POINT(2,2)),
    ST_LINESTRING(ST_POINT(1,0), ST_POINT(1,5)));
```

*Output*: `TRUE`

## ST_DISJOINT

Returns `true` if the specified geographies have no intersection, including boundaries. Both geographic arguments can be different types.

This function is the opposite of the **ST_INTERSECTS** function.

### Syntax

SQL

```
ST_DISJOINT(geo1, geo2)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2` to evaluate whether they intersect. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo1` to evaluate whether they intersect. |

Example

```sql
SELECT ST_DISJOINT(
    ST_POLYGON(ST_LINESTRING('LINESTRING(2 3, 2 4, 2 4, 2 3)')),
    ST_POLYGON(ST_LINESTRING('LINESTRING(1 2, 1 4, 1 5, 1 2)')));
```

*Output*: `TRUE`

# ST_DWITHIN

Returns `TRUE` if the geographies are within a specified distance in meters.

### Syntax

```sql
ST_DWITHIN(geo1, geo2, distance_meters)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2` to evaluate whether they are within the specified distance `distance_meters`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo1` to evaluate whether they are within the specified distance `distance_meters`. |
| `distance_meters` | `DOUBLE` | A numeric value that represents the number of meters to evaluate the distance between `geo1` and `geo2`. |

### Example

```sql
SELECT ST_DWITHIN(
    ST_POINT('POINT(1 1)'),
    ST_POINT('POINT(0 0)'),
    100);
```

*Output*: `FALSE`

# ST_EQUALS

Returns `TRUE` if both geographies are spatially equal.

### Syntax

SQL

```
ST_EQUALS(geo1, geo2)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2` to evaluate whether they are equal. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo1` to evaluate whether they are equal. |

Example

SQL

```
SELECT ST_EQUALS(
    ST_POLYGON(ST_LINESTRING('LINESTRING(10 10, 0 0, 0 0, 10 10)')),
    ST_POLYGON(ST_LINESTRING('LINESTRING(10 10, 0 0, 0 0, 10 10)')));
```

*Output*: `True`

# ST_INTERSECTS

Returns `TRUE` if the specified geographies intersect, including boundaries.

This function is the opposite of the **ST_DISJOINT** function.

### Syntax

```sql
ST_INTERSECTS(geo1, geo2)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2` to evaluate whether they intersect. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo1` to evaluate whether they intersect. |

### Example

```sql
SELECT ST_INTERSECTS(
    ST_POLYGON(ST_LINESTRING('LINESTRING(2 3, 2 4, 2 4, 2 3)')),
    ST_POLYGON(ST_LINESTRING('LINESTRING(1 2, 1 4, 1 5, 1 2)')));
```

*Output*: `FALSE`

## ST_ISCCW

Alias for **ST_ISPOLYGONCCW**.

## ST_ISCLOSED

Returns `TRUE` if an input `LINESTRING` has starting and ending points that are equal.

If you specify a `POLYGON` or `POINT` value, the function returns `true` if the specified geography is not empty.

### Syntax

```sql
ST_ISCLOSED(line)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `line` | `POINT`, `LINESTRING`, or `POLYGON` | If you specify a `LINESTRING` object, the function evaluates it to determine whether its starting and ending points are equal.<br>If you specify a `POLYGON` or `POINT` value, the function returns `true` if the specified geography is not empty. |

### Example

SQL

```
SELECT ST_ISCLOSED(
    ST_LINESTRING('LINESTRING(1 2, 1 3, 1 2)'));
```

*Output*: `TRUE`

# ST_ISPOLYGONCW

Alias for `BOOLNOT(ST_ISCCW(poly))`.

Returns `TRUE` if an input `POLYGON` has an exterior that is clockwise.

If the `POLYGON` argument is empty, this function returns `TRUE`. If the argument is NULL, this function returns NULL.

### Syntax

SQL

```
ST_ISPOLYGONCW(poly)
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `poly` | `POLYGON` | A `POLYGON` object to evaluate to determine whether its point values align in a clockwise direction. |

### Example

```sql
SELECT ST_ISPOLYGONCW(
    ST_POLYGON('POLYGON((0 0,1 0,1 1,0 1,0 0))'));
```

*Output*: `FALSE`

# ST_ISPOLYGONCCW

Alias for ST_ISCCW.

Returns `TRUE` if an input `POLYGON` has an exterior that is counter-clockwise.

If the `POLYGON` argument is empty, this function returns `TRUE`. If the argument is NULL, this function returns NULL.

### Syntax

```sql
ST_ISPOLYGONCCW(poly)
```

| Argument | Data Type | Description |
|---|---|---|
| `poly` | `POLYGON` | A `POLYGON` object to evaluate to determine whether its point values align in a counter-clockwise direction. |

### Example

```sql
SELECT ST_ISPOLYGONCCW(
    ST_POLYGON('POLYGON((0 0,1 0,1 1,0 1,0 0))'));
```

*Output*: `TRUE`

# ST_ISRING

Returns `TRUE` if the specified `LINESTRING` is closed and does not intersect itself. This function is equivalent to evaluating both **ST_ISCLOSED** and **ST_ISSIMPLE**.

If you specify a value other than `LINESTRING`, the function throws an error.

### Syntax

```
SQL

ST_ISRING(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `line` | `LINESTRING` | A `LINESTRING` object to evaluate to determine whether its starting and ending points are equal and whether it has no intersections. |

### Example

```
SQL

SELECT ST_ISRING(
    ST_LINESTRING('LINESTRING(1 2, 2 4, 1 3, 1 2)'));
```

*Output*: `TRUE`

## ST_ISSIMPLE

For `LINESTRING` values, this function returns `FALSE` if any line segments intersect anywhere besides the endpoints.

For `POLYGON` values, the function returns `FALSE` if either the exterior ring or any interior hole is not simple.

For `POINT` values, the function always returns `TRUE`.

### Syntax

```
SQL

ST_ISSIMPLE(geo)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to evaluate to determine if any points intersect.<br>For `LINESTRING` values, this function returns `FALSE` if any line segments intersect anywhere besides the endpoints.<br>For `POLYGON` values, the function returns `FALSE` if either the exterior ring or any interior hole is not simple.<br>For `POINT` values, the function always returns `TRUE`. |

### Example

```
SQL

SELECT ST_ISSIMPLE(
    ST_POLYGON('POLYGON((1 2, 3 4, 3 5, 1 2))'));
```

*Output*: `TRUE`

# ST_ISVALID

Returns `TRUE` if the specified geospatial value is a well-formed and valid geography according to the **OGC standards**.

`LINESTRING` values are not valid if they are composed of more than one `POINT` with the same coordinates.

`POLYGON` values are valid if they are composed of one external ring (shell) and zero or more internal rings. A ring is a `LINESTRING` where only the first and last `POINT` intersect each other. All internal rings need to be contained inside the shell, and none of the rings should intersect with each other in more than one `POINT`.

### Syntax

```sql
ST_ISVALID(geo1)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to evaluate to determine if it is a well-formed geography. |

### Example

```sql
SELECT ST_ISVALID(
    ST_LINESTRING('LINESTRING(1 2, 2 4)'));
```

*Output*: `TRUE`

## ST_OVERLAPS

Returns `TRUE` if both geographic arguments are of the same dimension and intersect, but neither contains the other. Returns NULL if either `geo1` or `geo2` is NULL.

### Syntax

```sql
ST_OVERLAPS(geo1, geo2)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for evaluation to determine if it is shaped similarly and intersects `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for evaluation to determine if it is shaped similarly and intersects `geo1`. |

### Example

```sql
SELECT ST_OVERLAPS(
    ST_LINESTRING(ST_POINT(0,0), ST_POINT(2,2)),
    ST_LINESTRING(ST_POINT(1,1), ST_POINT(3,3)));
```

*Output*: `TRUE`

# ST_POINTINSIDECIRCLE

Returns `TRUE` if the geographic object is inside a circle centered at the specified point coordinates and with the specified radius.

### Syntax

```sql
ST_POINTINSIDECIRCLE(geo, center_x, center_y, circle_radius)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for evaluation to determine if it is contained within a circle of the specified dimensions. |
| `center_x` | `DOUBLE` | The x coordinate of the center of the circle to evaluate. |
| `center_y` | `DOUBLE` | The y coordinate of the center of the circle to evaluate. |
| `circle_radius` | `DOUBLE` | The radius in meters of the circle to evaluate. |

### Example

```sql
SELECT ST_POINTINSIDECIRCLE(
    ST_POINT(1, 3), 1, 2, 3000000);
```

*Output*: `TRUE`

# ST_RELATE

Returns the **DE-9IM** intersection string that represents the nature of the intersection with the specified geographies. If you specify an intersection pattern as the third argument, this function returns `TRUE` if the intersection of the geographies satisfies the pattern and `FALSE` otherwise.

### Syntax

SQL

```
ST_RELATE(geo1, geo2, [, intersectionPattern])
```

| Parameter | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to relate with `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to relate with `geo1`. |
| `intersectionPattern` | `STRING` | Optional.<br>Intersection pattern to query the nature of the intersection of `geo1` and `geo2`.<br>Must contain exactly 9 characters, corresponding to the component (interior, boundary, or exterior) intersections considered by DE-9IM. Supported characters are:<br>* `T` — Components intersect.<br>* `F` — Components do not intersect.<br>* `0` — Component intersection is zero-dimensional.<br>* `1` — Component intersection is 1-dimensional.<br>* `2` — Component intersection is 2-dimensional.<br>* `*` — Specify no restriction on the component intersection. |

### Examples

Determine the nature of the intersection between the point `(0.0, 0.0)` and the line from `-1 0` to `1 0`. This function returns the DE-9IM string `0FFFFF102`, which means that the boundaries do not intersect at all, but there is evidence of an intersection at the zero, one, and two-dimensional spaces.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

```sql
SELECT ST_RELATE(ST_POINT(0.0, 0.0),
    ST_LINESTRING('LINESTRING(-1 0, 1 0)'));
```

*Output: * `OFFFFF102`

Determine whether the intersection between the point `(0.0, 0.0)` and the line from `-1 0` to `1 0` follows the DE-9IM pattern string `TF*FFF102`. This function returns `TRUE`, which means the nature of the intersection between these two geographies conforms to this pattern.

```sql
SELECT ST_RELATE(ST_POINT(0.0, 0.0),
    ST_LINESTRING('LINESTRING(-1 0, 1 0)'), 'TF*FFF102');
```

*Output: * `TRUE`

# ST_TOUCHES

Returns `TRUE` if the only `POINT` values in common between the two geographic arguments lie in the union of their boundaries.

### Syntax

```sql
ST_TOUCHES(geo1, geo2)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for evaluation to determine if it touches `geo2`. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object for evaluation to determine if it touches `geo1`. |

### Example

```sql
SELECT ST_TOUCHES(
    ST_LINESTRING('LINESTRING(1.0 3.0, 0.0 3.0)'),
    ST_LINESTRING('LINESTRING(1.0 3.0, 2.0 3.0)'));
```

*Output*: `TRUE`

# ST_WITHIN

Returns `TRUE` if the geography specified by the first argument is fully inside the geography specified by the second argument.

`ST_WITHIN(geo1, geo2)` is equivalent to `ST_CONTAINS(geo2, geo1)`. For details, see **ST_CONTAINS**.

### Syntax

```sql
ST_WITHIN(geo1, geo2)
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo2` to evaluate whether it is fully inside this second geography. |
| `geo2` | `POINT`, `LINESTRING`, or `POLYGON` | A geospatial object to be compared to `geo1` to evaluate whether it contains the first geography. |

### Example

```sql
SELECT ST_WITHIN(
    ST_POINT(1, 1),
    ST_LINEFROMTEXT('LINESTRING(0 0, 1 1, 2 2)')
);
```

*Output*: `true`

# Spatiotemporal Measurement

Reference for OcientGeo spatiotemporal measurement functions that compute distance, duration, and velocity across space and time for trajectory analytics.

OcientGeo™ spatiotemporal measurement functions can perform basic calculations on geospatial data that is paired with TIMESTAMP data.

## ST_DISTANCE

Returns the two-dimensional interpolated minimum simultaneous distance between two `LINESTRING-TIMESTAMP` array pairs in the specified unit of measurement.

If any argument is NULL or empty, the function returns NULL. If either `LINESTRING-TIMESTAMP` array pair has a mismatched number of points and timestamps, the function returns an error.

Behavior is undefined if either timestamp array is not monotonically increasing.

SQL

```
ST_DISTANCE(geo1, ts_arr1, geo2, ts_arr2, units [, use_spheroid] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `LINESTRING` | A geospatial object to be evaluated for its minimum cotemporal distance from `geo2`. |
| `ts_arr1` | `TIMESTAMP ARRAY` | A timestamp array that is paired with `geo1`. |
| `geo2` | `LINESTRING` | A geospatial object to be evaluated for its minimum cotemporal distance from `geo1`. |
| `ts_arr2` | `TIMESTAMP ARRAY` | A timestamp array that is paired with `geo2`. |
| `units` | `STRING` | The unit of measurement used for the minimum cotemporal distance.<br>Accepted options include `'FEET'`, `'KILOMETERS'`, `'MILES'`, or `'METERS'`.<br>The default value is `'METERS'`. |
| `use_spheroid` | `BOOLEAN` | Optional. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Argument | Data Type | Description |
| --- | --- | --- |
| | | If you set this argument to `TRUE`, this function uses a spheroid model instead of a spherical model.<br><br>The default value is `FALSE`. |

### Example

SQL

```
SELECT ST_DISTANCE(
        ST_LINESTRING('linestring(0 0,0 12)'),
        TIMESTAMP [](
            '2020-07-04 07:00:00.000000000',
            '2020-07-04 11:00:00.000000000'),
        ST_LINESTRING('linestring(0 0,6 0)'),
        TIMESTAMP [](
            '2020-07-04 08:00:00.000000000',
            '2020-07-04 10:00:00.00000000'),
        'MILES',
        TRUE);
```

*Output*: `206.124`

To use ST_DISTANCE as a spatial function to calculate the minimum distance between two points, see the **ST_DISTANCE** function in the Spatial Measurement section.

# ST_MAXDISTANCE

Returns the two-dimensional interpolated maximum cotemporal distance between two `LINESTRING-TIMESTAMP` array pairs in the specified unit of measurement.

If any argument is NULL or empty, the function returns NULL. If either `LINESTRING-TIMESTAMP` array pair has a mismatched number of points and timestamps, the function returns an error.

Behavior is undefined if either timestamp array is not monotonically increasing.

SQL

```
ST_MAXDISTANCE(geo1, ts_arr1, geo2, ts_arr2, units [, use_spheroid] )
```

| Argument | Data Type | Description |
|---|---|---|
| `geo1` | `LINESTRING` | A geospatial object to be evaluated for its maximum cotemporal distance from `geo2`. |
| `ts_arr1` | `TIMESTAMP ARRAY` | A `TIMESTAMP ARRAY` that is paired with `geo1`. |
| `geo2` | `LINESTRING` | A geospatial object to be evaluated for its maximum cotemporal distance from `geo1`. |
| `ts_arr2` | `TIMESTAMP ARRAY` | A `TIMESTAMP ARRAY` that is paired with `geo2`. |
| `units` | `STRING` | The unit of measurement used for the maximum cotemporal distance.<br>Accepted options include `'FEET'`, `'KILOMETERS'`, `'MILES'`, or `'METERS'`.<br>The default value is `'METERS'`. |
| `use_spheroid` | `BOOLEAN` | Optional.<br><br>If you set this argument to `TRUE`, this function uses a spheroid model instead of a spherical model.<br><br>The default value is `FALSE`. |

## Example

SQL

```
SELECT ST_MAXDISTANCE(
    ST_LINESTRING('linestring(0 0,0 12)'),
        TIMESTAMP[]('2020-07-04 07:00:00.000000000', '2020-07-04 11:00:00.00000000C
    ST_LINESTRING('linestring(0 0,6 0)'),
        TIMESTAMP[]('2020-07-04 08:00:00.000000000', '2020-07-04 10:00:00.00000000'
    'MILES',
    TRUE);
```

*Output*: `743.83`

To use ST_MAXDISTANCE as a spatial function to calculate the maximum distance between two points, see the **ST_MAXDISTANCE** function in the Spatial Measurement section.

# ST_TOTALSECONDSININTERSECTION

Returns the total number of seconds spent in the intersection result calculated by the spatiotemporal version of **ST_INTERSECTION**.

Execute this function only with the result from ST_INTERSECTION. If the input is an empty, correctly typed tuple, this function returns 0 seconds. If the input is NULL, this function returns NULL.

SQL

```
ST_TOTALSECONDSININTERSECTION(tpl)
```

| Argument | Data Type | Description |
|---|---|---|
| `tpl` | Tuple of `LINESTRING-TIMESTAMP` pairs | A tuple of `LINESTRING-TIMESTAMP` pairs used to evaluate how long an intersection existed. |

### Example

SQL

```
SELECT ST_TOTALSECONDSININTERSECTION(
    ST_INTERSECTION(
        ST_LINESTRING('LINESTRING(1 1,2 2,1 1)'),
            TIMESTAMP[](
                '2020-07-04 07:00:00.000000000',
                '2020-07-04 11:00:00.000000000',
                '2020-07-04 12:00:00.000000000'),
        ST_LINESTRING('LINESTRING(2 2,1 1)')));
```

*Output*: `18000.0`

# Spatiotemporal Operators

Reference for OcientGeo spatiotemporal operators that combine spatial and temporal predicates to analyze moving objects, trajectories, and geometries.

OcientGeo™ spatiotemporal operators perform calculations on geospatial data using an array of TIMESTAMP arguments.

## ST_LONGESTLINE

With the specified two `LINESTRING-TIMESTAMP ARRAY` pairs, this function returns a two-point `LINESTRING` that represents the maximum distance between points at a concurrent time.

If the two `LINESTRING` values do not overlap temporally, this function returns NULL.

### Syntax

```
SQL

ST_LONGESTLINE(linestring1, ts_arr1, linestring2, ts_arr2 [, use_spheroid] )
```

| Argument | Data Type | Description |
|---|---|---|
| `linestring1` | `LINESTRING` | A geospatial object to be evaluated for its maximum cotemporal distance from `linestring2`. |
| `ts_arr1` | `TIMESTAMP ARRAY` | A timestamp array that is paired with `linestring1`. Behavior is undefined if this timestamp array is not monotonically increasing. |
| `linestring2` | `LINESTRING` | A geospatial object to be evaluated for its maximum cotemporal distance from `linestring1`. |
| `ts_arr2` | `TIMESTAMP ARRAY` | A timestamp array that is paired with `linestring2`. Behavior is undefined if this timestamp array is not monotonically increasing. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this argument to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### Example

SQL

```
SELECT ST_LONGESTLINE(
        ST_MAKELINE(ST_POINT(0, 0), ST_POINT(0, 12)),
        TIMESTAMP []('2020-07-04 07:00:00.000000000',
            '2020-07-04 11:00:00.000000000'),
        ST_MAKELINE(ST_POINT(0, 0), ST_POINT(8, 0)),
        TIMESTAMP []('2020-07-04 08:00:00.000000000',
            '2020-07-04 10:00:00.000000000'));
```

*Output*: `LINESTRING(0 9, 8 0)`

To use ST_LONGESTLINE as a spatial function to calculate the longest line between two points, see the **ST_LONGESTLINE** function.

## ST_LINEGETALLTIMESATPOINT

Returns a timestamp array of all times when the specified `LINESTRING` value intersects the specified `POINT` value. If the line never intersects the point, then the function returns an empty timestamp array.

If the specified inputs are NULL, the function returns NULL.

This function cannot represent intervals of time where the line was stationary at a point, therefore, use this function only for mobile paths. If the path is stationary, use the **ST_INTERSECTION** function as it can represent intervals of time spent intersecting a stationary `LINESTRING`.

### Syntax

SQL

```
ST_LINEGETALLTIMESATPOINT(line, timestamp_arr, point)
```

| Argument | Data Type | Description |
|---|---|---|
| `line` | `LINESTRING` | A geospatial `LINESTRING` to be evaluated for all time values in the `timestamp_arr` when it intersects the specified `point` value.<br>If this value is empty, the function returns an empty timestamp array.<br>This value must be the same size as the `timestamp_arr`. |
| `timestamp_arr` | `TIMESTAMP ARRAY` | A `TIMESTAMP ARRAY` that is paired with the `line` argument.<br>`timestamp_arr` must be the same size as the `line` value.<br>Behavior is undefined if the timestamp array is not monotonically increasing. |
| `point` | `POINT` | A geospatial point to be evaluated for the time values when the point intersects the `line` value. |

### Example

SQL

```
SELECT ST_LINEGETALLTIMESATPOINT(
        ST_MAKELINE(ST_POINT(0, 0), ST_POINT(4, 0), ST_POINT(0, 0)),
        TIMESTAMP []('2020-07-04 07:00:00.000000000',
            '2020-07-04 08:00:00.000000000',
            '2020-07-04 09:00:00.000000000'),
        ST_POINT(0, 0));
```

*Output*: `TIMESTAMP[]('2020-07-04 07:00:00.000000000', '2020-07-04 09:00:00.000000000')`

## ST_LINEGETPOINTATTIME

Returns a `POINT` within the bounds of the specified `LINESTRING` that corresponds to the interpolated point at the specified `TIMESTAMP` value.

The specified `TIMESTAMP` value does not need to be an actual value explicitly included in the array. The function interpolates the corresponding point, which means that the function approximates the point coordinates from the surrounding values.

The `LINESTRING` and `TIMESTAMP` array must be the same size. If the timestamp array is not monotonically increasing, the behavior is undefined.

### Syntax

SQL

```
ST_LINEGETPOINTATTIME(line, timestamp_arr, time_for_point)
```

| Argument | Data Type | Description |
|---|---|---|
| `line` | `LINESTRING` | A geospatial `LINESTRING` to be evaluated for an interpolated point, based on the `time_for_point` value. This value must be the same size as the `timestamp_arr`. |
| `timestamp_arr` | `TIMESTAMP ARRAY` | A `TIMESTAMP ARRAY` that is paired with the `line` argument.<br>`timestamp_arr` must be the same size as the `line` value.<br>Behavior is undefined if the timestamp array is not monotonically increasing. |
| `time_for_point` | `TIMESTAMP` | A time value to approximate a `POINT` value on the `line` argument, based on interpolating the values in `timestamp_arr`.<br>If this time value precedes the first value in `timestamp_arr`, the function returns the first `POINT` on `line`.<br>Similarly, if this time value comes after the last value in `timestamp_arr`, the function returns the last `POINT` on `line`. |

### Example

SQL

```
SELECT ST_LINEGETPOINTATTIME(
    ST_MAKELINE(ST_POINT(0, 0), ST_POINT(4, 0)),
    TIMESTAMP[]('2020-07-04 07:00:00.000000000', '2020-07-04 08:00:00.000000000'),
    TIMESTAMP('2020-07-04 07:30:00.000000000'));
```

*Output*: `POINT(2, 0)`

# ST_LINEGETTIMEATPOINT

Returns the interpolated time of the specified `POINT` on the specified `LINESTRING` that is paired with a `TIMESTAMP ARRAY`.

The `LINESTRING` and `TIMESTAMP ARRAY` must be the same size.

### Syntax

SQL

```
ST_LINEGETTIMEATPOINT(line, timestamp_arr, point_for_time)
```

| Argument | Data Type | Description |
|---|---|---|
| `line` | `LINESTRING` | A geospatial line to be evaluated for an interpolated time value based on the `point_for_time` value.<br>This value must be the same size as the `timestamp_arr`. |
| `timestamp_arr` | `TIMESTAMP ARRAY` | A timestamp array that is paired with the `line` argument.<br>`timestamp_arr` must be the same size as the `line` value.<br>Behavior is undefined if the timestamp array is not monotonically increasing. |
| `point_for_time` | `POINT` | A `POINT` value to approximate a `TIMESTAMP` value on the `line` argument, based on interpolating the values in `timestamp_arr`.<br>If `line` intersects this `POINT` value multiple times, then the function returns the earliest time. |

### Example

SQL

```
SELECT ST_LINEGETTIMEATPOINT(
    ST_MAKELINE(ST_POINT(0, 0), ST_POINT(4, 0)),
    TIMESTAMP[]('2020-07-04 07:00:00.000000000', '2020-07-04 08:00:00.000000000'),
    ST_POINT(2, 0));
```

*Output*: `TIMESTAMP('2020-07-04 07:30:00.000000000')`

Ocient Proprietary and Confidential

# ST_INTERSECTION

Returns a tuple that represents the intersection of a spatiotemporal `LINESTRING` with a static geography.

If the specified static geography is a `POINT`, the returned value is a tuple that contains a paired `POINT` array and `TIMESTAMP` array. If the specified static geography is a `LINESTRING` or `POLYGON`, then the returned value is a `LINESTRING` array paired with a two-dimensional `TIMESTAMP` array.

### Syntax

SQL

```
ST_INTERSECTION(line, timestamp_arr, intersection_point)
```

| Argument | Data Type | Description |
|---|---|---|
| `line` | `LINESTRING` | A geospatial line to be evaluated for all intersections with the `intersection_point`.<br>If this argument is empty, the function returns NULL. |
| `timestamp_arr` | `TIMESTAMP ARRAY` | A `TIMESTAMP ARRAY` that is paired with the `line` argument.<br>`timestamp_arr` must be the same size as the `line` value.<br>Behavior is undefined if the timestamp array is not monotonically increasing. |
| `intersection_point` | `POINT`, `LINESTRING`, or `POLYGON` | A geographic object to evaluate for all intersections with the `line` argument.<br>If this value is empty, the function returns an empty tuple. If the value is NULL, the function returns NULL. |

### Example

SQL

```
SELECT ST_INTERSECTION(
    ST_LINESTRING('LINESTRING(1 1,2 2,3 3)'),
    TIMESTAMP[]('2020-07-04 07:00:00.000000000', '2020-07-04 11:00:00.000000000',
         '2020-07-04 12:00:00.000000000'),
    ST_POLYGON('POLYGON((2 2,3 2,3 3,3 2,2 2))'));
```

*Output*: `TUPLE(LINESTRING[](ST_LINESTRING('LINESTRING(2 2)'), ST_LINESTRING('LINESTRING(3 3)')), ARRAY[ARRAY[TIMESTAMP '2020-07-04 11:00:00.000000000'], ARRAY[TIMESTAMP '2020-07-04 12:00:00.000000000']])`

# ST_SHORTESTLINE

When you specify two `LINESTRING-TIMESTAMP ARRAY` pairs, this function returns a `LINESTRING` with two points that represents the minimum distance between points at a concurrent time.

If the two linestrings do not overlap temporally, this function returns NULL.

### Syntax

SQL

```
ST_SHORTESTLINE(linestring1, ts_arr1, linestring2, ts_arr2 [, use_spheroid ])
```

| Argument | Data Type | Description |
|---|---|---|
| `linestring1` | `LINESTRING` | A geospatial object to be evaluated for its minimum cotemporal distance from `linestring2`. |
| `ts_arr1` | `TIMESTAMP ARRAY` | A timestamp array that is paired with `linestring1`. |
| `linestring2` | `LINESTRING` | A geospatial object to be evaluated for its minimum cotemporal distance from `linestring1`. |
| `ts_arr2` | `TIMESTAMP ARRAY` | A timestamp array that is paired with `linestring2`. |
| `use_spheroid` | `BOOLEAN` | Optional.<br>If you set this argument to `TRUE`, this function uses a spheroid model instead of a spherical model.<br>Defaults to `FALSE`. |

### Example

SQL

```
SELECT ST_SHORTESTLINE(
    ST_MAKELINE(ST_POINT(0, 0), ST_POINT(4, 0)),
    TIMESTAMP[]('2020-07-04 07:00:00.000000000', '2020-07-04 08:00:00.000000000'),
    ST_MAKELINE(ST_POINT(3, 0), ST_POINT(4, 8)),
    TIMESTAMP[]('2020-07-04 07:00:00.000000000', '2020-07-04 07:30:00.000000000'));
```

*Output*: `LINESTRING(0.09295649430902601 0, 3.0461764508256914 0.37184471667525754)`

To use ST_SHORTESTLINE as a spatial function to calculate the shortest line between two points, see the **ST_SHORTESTLINE** function.

# Machine Learning Model Functions

Reference for OcientML model functions used in SQL queries to invoke trained machine learning models for prediction, scoring, and feature engineering tasks.

OcientML™ functionality supports these SQL functions for machine learning models.

ⓘ The scope of a machine learning model is the schema.

## Supported Machine Learning Models

Supported machine learning models and reference material are divided into these categories.

ⓘ For functions to help organize data before training a model, see **Data Preparation**.

### Regression Models

- **Simple Linear Regression**
- **Multiple Linear Regression**
- **Vector Autoregression**
- **Polynomial Regression**
- **Linear Combination Regression**
- **Nonlinear Regression**
- **Gradient Boosted Trees**
- **Regression Tree**

### Classification Models

- **K Nearest Neighbor Classification**
- **Naive Bayes Classification**
- **Decision Tree**
- **Random Forest**

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

- **Logistic Regression**
- **Support Vector Machine**
- **Gradient Boosted Trees**

### Clustering and Dimension Reduction Models

- **Principal Component Analysis**
- **K-Means Clustering**
- **Gaussian Mixture**
- **Linear Discriminant Analysis**

### Ensemble Models

- **Bagging**
- **Boosting**
- **Stacking**

### Other Models

- **Association Rules**
- **Multi-Layer Perceptron (MLP)**
- **Undersampling**

For a view of the full list of model options, see **Machine Learning Model Options**.

## Execute a Query Using a Machine Learning Model

To create a machine learning model and manage the model, see **Machine Learning Models** for the corresponding syntax. After you create the model, you can execute a query using the model with this syntax.

#### Syntax

SQL

```
SELECT model_name ( expression [, ... ] ) FROM table_reference
```

| Parameter | Data Type | Description |
| --- | --- | --- |
| `model_name` | identifier | The name of a machine learning model created using a `CREATE MODEL` SQL statement. The model name must be a valid identifier and reference an existing trained model. |
| `expression` | identifier<br>string<br>numeric | One or more expressions that serve as input features for the machine learning model evaluation. These expressions must match the expected input schema that the model was trained on.<br><br>Expressions can be any combination of literal values, column names, arithmetic expressions, and function invocations, with parentheses for grouping. |
| `table_reference` | identifier | The name of a table, view, or subquery that provides the data for model evaluation. The table must contain columns or computed expressions that match the expected input features of the model. |

### Example

Create a table with data for the model.

SQL

```
CREATE TABLE mldemo.mlr AS (SELECT a.c1 AS x1, b.c1 AS x2, 1 + 2*a.c1 + 3*b.c1 AS y
    FROM sys.dummy10 a, sys.dummy10 b);
Modified 100 rows
```

Create a multiple linear regression model based on the data.

SQL

```
CREATE MLMODEL mlr_model TYPE MULTIPLE LINEAR REGRESSION ON (SELECT * FROM mldemo.m
options('metrics' -> 'true');
Modified 0 rows
```

Execute a `SELECT` query against the multiple linear regression to see the actual and predicted values. Limit the result set to 10 rows.

SQL

```sql
SELECT x1, x2, y AS actual, mlr_model(x1, x2) AS predicted
    FROM mldemo.mlr
    LIMIT 10;
```

*Output*

Text

```
x1          x2          actual              predicted
-------------------------------------------------------------
6           1           16                  15.999999999999975
6           2           19                  18.999999999999975
6           3           22                  21.999999999999975
6           4           25                  24.999999999999975
6           5           28                  27.999999999999975
6           6           31                  30.999999999999975
6           7           34                  33.99999999999997
6           8           37                  36.99999999999997
6           9           40                  39.99999999999997
6           10          43                  42.99999999999997

Fetched 10 rows
```

# Machine Learning Meta Functions

Machine Learning meta functions provide additional ways to invoke a trained model. Unlike calling a model directly by name, meta functions wrap the model invocation and control how the model produces its output.

## predict

The `predict` meta function behaves the same as invoking the model directly as a function. The function returns the value predicted by the specified model for the input features.

### Syntax

SQL

```
SELECT predict( model_name( [ hyperargument [, ...] ] ), feature [, ...] ) FROM tab
```

| Parameter | Data Type | Description |
|---|---|---|
| `model_name` | identifier | The name of a trained machine learning model. |
| `hyperargument` | varies | Optional model-specific arguments that control how the model makes predictions. For example, the component index in principal component analysis, or a voting flag for ensemble models. |
| `feature` | varies | One or more input feature expressions matching the schema the model was trained on. |

### Example

SQL

```
SELECT predict(my_model(), x1, x2) FROM my_table;
```

Because many models do not require hyperarguments, the hyperargument list and its surrounding parentheses are optional.

SQL

```
SELECT predict(my_model, x1, x2) FROM my_table;
```

## predict_probabilities

The `predict_probabilities` meta function returns a tuple of label-score pairs for each possible class the model can predict. The model assigns each label a score determined by the input features. Then, the model sorts the pairs in decreasing order of score, with ties broken by decreasing label value.

This function is supported only for these model types:

- Decision Tree
- Random Forest

- Logistic Regression
- Support Vector Machine
- Gaussian Discriminant Analysis
- Gaussian Mixture Model
- MLP (only when trained with softmax output for classification)

All other model types reject the `predict_probabilities` function, including all regression variants, Naive Bayes, Linear Discriminant Analysis, Principal Component Analysis, ensemble models (Bagging, Stacking), K-Means, Power Iteration Clustering, K Nearest Neighbors, and anomaly detection models. Undersampling models do not support either meta function because they produce output tables rather than row-level predictions.

### Syntax

```
SQL
SELECT predict_probabilities( model_name( [ hyperargument [, ...] ] ), feature [, .
```

| Parameter | Data Type | Description |
|---|---|---|
| `model_name` | identifier | The name of a trained machine learning model. |
| `hyperargument` | varies | Optional model-specific arguments that control how the model makes predictions. |
| `feature` | varies | One or more input feature expressions matching the schema the model was trained on. |

### Example

```
SQL
SELECT predict_probabilities(my_classifier(), x1, x2, x3) FROM my_table;
```

# Data Preparation

Use Ocient SQL lag generators and vector assemblers to simplify time series feature engineering for regression, VAR, and neural network model inputs.

Lag generator and vector assembler SQL functions simplify generating and organizing lagged features for time series data. Each function expands into standard SQL during query processing, so developers can reduce boilerplate and create feature sets with minimal code.

These functions fall into two main types:

- **Lag Generator Functions** — Create individual lag feature columns.
- **Vector Assembler Functions** — Group generated lag columns into vectors.

Developers can apply lag features across many Ocient®-supported models, including:

- Simple Linear Regression (univariate forecasting with lag inputs)
- Multiple Linear Regression (multivariate regression with lagged predictors)
- Polynomial Regression (regression with higher-order lagged terms)
- Linear Combination Regression (custom functions of lagged inputs)
- Nonlinear Regression (arbitrary functions that include lag variables)
- Feedforward Neural Networks (lagged features as input vectors)
- Vector Autoregression (VAR) (multivariate time series with structured lag vectors)
- Autoregression (univariate time series modeled through lagged values)
- Vector Valued Regression (multivariate dependent variables with lagged inputs)

The functions provide general-purpose utilities for time series feature engineering. In particular, VAR models benefit the most from lag functions because the models require large numbers of structured lag vectors.

## Lag Generator Functions

Lag generator functions provide options for creating lagged columns for one or more variables in a single statement.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

These functions follow the syntax rules of window aggregate functions as they define the window for the lag computation with an `OVER` and `ORDER BY` clause. For details, see **Window Aggregate Functions**.

The window parameters of lag generator functions are represented in these examples by `<window_specification>`.

## LAGS

Generates a series of lagged columns for a single variable in one statement. This function simplifies univariate time-series feature creation.

### Syntax

SQL

```
LAGS(expression, start_lag, end_lag [, step])
    OVER (<window_specification>)
```

| Argument | Type | Description |
|---|---|---|
| `expression` | ANY | The column or expression to lag. |
| `start_lag` | INTEGER | First lag to generate. This value must be less than the `end_lag` value. |
| `end_lag` | INTEGER | Last lag to generate. This value must be greater than the `start_lag` value. |
| `step` | INTEGER | Optional.<br>Defines the gap between successive lags. Must be a positive integer.<br>If unspecified, this value defaults to `1`. |

### Example

This query produces three lagged columns ( `sales_lag1` , `sales_lag2` , `sales_lag3` ) from the sales column.

```sql
SELECT
    LAGS(sales, 1, 3) OVER (ORDER BY day)
FROM store_sales;
```

*Output*

```sql
sales_lag1 | sales_lag2 | sales_lag3
-----------+------------+------------
NULL       | NULL       | NULL
100        | NULL       | NULL
120        | 100        | NULL
130        | 120        | 100
```

## LAGS_ZEROFILL

Generates lagged columns for a single variable and replaces NULL values with `0`.

### Syntax

```sql
LAGS_ZEROFILL(expression, start_lag, end_lag [, step])
    OVER (<window_specification>)
```

| Argument | Type | Description |
|---|---|---|
| `expression` | ANY | The column or expression to lag. |
| `start_lag` | INTEGER | First lag to generate. This value must be less than the `end_lag` value. |
| `end_lag` | INTEGER | Last lag to generate. This value must be greater than the `start_lag` value. |
| `step` | INTEGER | Optional.<br>Defines the gap between successive lags. Must be a positive integer.<br>If unspecified, this value defaults to `1`. |

### Example

This query produces three lagged sales columns and replaces NULL values with 0.

```sql
SELECT
    LAGS_ZEROFILL(sales, 1, 3) OVER (ORDER BY day)
FROM store_sales;
```

*Output*

```sql
sales_lag1 | sales_lag2 | sales_lag3
-----------+------------+------------
0          | 0          | 0
100        | 0          | 0
120        | 100        | 0
130        | 120        | 100
```

## MULTI_LAGS

Generates lagged columns for multiple variables at once. This function is intended primarily for creating features for multivariate time-series models.

### Syntax

```sql
MULTI_LAGS(expr1, expr2, [ ,... ] start_lag, end_lag [, step])
    OVER (<window_specification>)
```

| Argument | Type | Description |
|---|---|---|
| `expr1, expr2, [ ,... ]` | ANY | One or more columns or expressions to lag. Applies the same lag range and step to each input. |
| `start_lag` | INTEGER | First lag to generate. This value must be less than the `end_lag` value. |

| Argument | Type | Description |
|---|---|---|
| `end_lag` | INTEGER | Last lag to generate. This value must be greater than the `start_lag` value. |
| `step` | INTEGER | Optional.<br>Defines the gap between successive lags. Must be a positive integer.<br>If unspecified, this value defaults to `1`. |

**Example** This query creates four lagged columns for both `interest_rate` and `gdp_growth`.

SQL

```
SELECT
    MULTI_LAGS(interest_rate, gdp_growth, 1, 4) OVER (ORDER BY quarter)
FROM economic_data;
```

*Output*

SQL

```
interest_rate_lag1 | interest_rate_lag2 | interest_rate_lag3 | interest_rate_lag4 |
-------------------+--------------------+--------------------+--------------------+
NULL               | NULL               | NULL               | NULL               |
2.5                | NULL               | NULL               | NULL               |
2.7                | 2.5                | NULL               | NULL               |
2.8                | 2.7                | 2.5                | NULL               |
```

## MULTI_LAGS_ZEROFILL

Generates lagged columns for multiple variables and replaces NULL values with `0`.

### Syntax

SQL

```
MULTI_LAGS_ZEROFILL(expr1, expr2, [ ,... ] start_lag, end_lag [, step])
    OVER (<window_specification>)
```

| Argument | Type | Description |
| --- | --- | --- |
| `expr1, expr2, [ ,... ]` | ANY | One or more columns or expressions to lag. Applies the same lag range and step to each input. |
| `start_lag` | INTEGER | First lag to generate. This value must be less than the `end_lag` value. |
| `end_lag` | INTEGER | Last lag to generate. This value must be greater than the `start_lag` value. |
| `step` | INTEGER | Optional.<br>Defines the gap between successive lags. Must be a positive integer.<br>If unspecified, this value defaults to `1`. |

**Example** This query generates four lagged columns each for `x1`, `x2`, and `x3`, replacing missing values with 0.

SQL

```
SELECT
    MULTI_LAGS_ZEROFILL(x1, x2, x3, 1, 4) OVER (ORDER BY time_col)
FROM public.my_time_series_table;
```

*Output*

SQL

```
x1_lag1 | x1_lag2 | x1_lag3 | x1_lag4 | x2_lag1 | x2_lag2 | x2_lag3 | x2_lag4 | x3_
--------+---------+---------+---------+---------+---------+---------+---------+----
0       | 0       | 0       | 0       | 0       | 0       | 0       | 0       | 0
10      | 0       | 0       | 0       | 20      | 0       | 0       | 0       | 30
11      | 10      | 0       | 0       | 21      | 20      | 0       | 0       | 31
12      | 11      | 10      | 0       | 22      | 21      | 20      | 0       | 32
```

# Vector Assembler Function

A vector assembler function provides options for grouping multiple lagged columns into structured vectors in a single statement. This function makes preparing input data for

time series models easier, especially those that require organized lag structures, such as VAR.

## LAG_VECTORS

Groups lagged columns generated by the `MULTI_LAGS` or `MULTI_LAGS_ZEROFILL` functions into vector columns. Models such as VAR require these structured lag vectors.

The resulting vectors are named `lag_vector_`.

### Syntax

SQL

```
LAG_VECTORS(expr1, expr2, [ ..., ] start_lag, end_lag [, step])
```

| Argument | Type | Description |
|---|---|---|
| `expr1, expr2, [ ,... ]` | NUMERIC | Two or more lagged columns to group. Applies the same lag range and step to each input. |
| `start_lag` | INTEGER | First lag to assemble. This value must be less than the `end_lag` value. |
| `end_lag` | INTEGER | Last lag to assemble. This value must be greater than the `start_lag` value. |
| `step` | INTEGER | Optional.<br>Defines the gap between successive lags. Must be a positive integer.<br>If unspecified, this value defaults to `1`. |

### Examples

#### Assemble Lagged Columns into Vectors

This query uses `MULTI_LAGS_ZEROFILL` to generate lagged columns for `x1`, `x2`, and `x3`, then uses `LAG_VECTORS` to group them into `lag_vector1` through `lag_vector4`.

SQL

```
SELECT
    {x1, x2, x3} AS current_vector,
    LAG_VECTORS(x1, x2, x3, 1, 4)
FROM (
    SELECT
        x1, x2, x3,
        MULTI_LAGS_ZEROFILL(x1, x2, x3, 1, 4) OVER (ORDER BY time_col)
    FROM public.my_time_series_table
) s;
e;
```

*Output*

SQL

```
current_vector | lag_vector1 | lag_vector2 | lag_vector3 | lag_vector4
---------------+-------------+-------------+-------------+-------------
{10, 20, 30}   | {0, 0, 0}   | {0, 0, 0}   | {0, 0, 0}   | {0, 0, 0}
{11, 21, 31}   | {10, 20, 30}| {0, 0, 0}   | {0, 0, 0}   | {0, 0, 0}
{12, 22, 32}   | {11, 21, 31}| {10, 20, 30}| {0, 0, 0}   | {0, 0, 0}
{13, 23, 33}   | {12, 22, 32}| {11, 21, 31}| {10, 20, 30}| {0, 0, 0}
```

### Prepare Data for a VAR Model

This example shows how to prepare training data for a VAR model with three variables ( `x1` , `x2` , `x3` ) and four lags. The example demonstrates how the lag generator functions and vector assembler can simplify feature creation compared to writing out every LAG expression manually.

- `MULTI_LAGS_ZEROFILL` generates all individual lagged columns ( `x1_lag1` … `x3_lag4` ) in a single call, replacing NULL values with zero.
- `LAG_VECTORS` automatically groups these lagged columns into vector inputs ( `lag_vector1` … `lag_vector4` ), which the model requires.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE MLMODEL my_var_model
TYPE VECTOR_AUTOREGRESSION ON (
    SELECT
        {x1, x2, x3},
        LAG_VECTORS(x1, x2, x3, 1, 4)
    FROM (
        SELECT
            x1, x2, x3,
            MULTI_LAGS_ZEROFILL(x1, x2, x3, 1, 4) OVER (ORDER BY t)
        FROM public.my_time_series_table
    )
)
OPTIONS (
    'numVariables' -> '3',
    'numLags'      -> '4'
);
```

### Prepare Data for a VAR Model with Manual Vector Assembly

This version of the univariate regression example uses repeated `LAG` invocations instead of the `LAGS` function. Although it produces the exact same set of lagged features ( `sales_lag1` , `sales_lag2` , `sales_lag3` ), the query requires writing each `LAG` expression manually. This makes the SQL longer, more repetitive, and harder to maintain compared to the concise single-line `LAGS` version.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE MLMODEL my_var_model_manual
TYPE VECTOR_AUTOREGRESSION ON (
    SELECT
        {x1, x2, x3},
        {x1_lag1, x2_lag1, x3_lag1},
        {x1_lag2, x2_lag2, x3_lag2},
        {x1_lag3, x2_lag3, x3_lag3},
        {x1_lag4, x2_lag4, x3_lag4}
    FROM (
        SELECT
            x1, x2, x3,
            COALESCE(LAG(x1, 1) OVER (ORDER BY t), 0) AS x1_lag1,
            COALESCE(LAG(x1, 2) OVER (ORDER BY t), 0) AS x1_lag2,
            COALESCE(LAG(x1, 3) OVER (ORDER BY t), 0) AS x1_lag3,
            COALESCE(LAG(x1, 4) OVER (ORDER BY t), 0) AS x1_lag4,
            COALESCE(LAG(x2, 1) OVER (ORDER BY t), 0) AS x2_lag1,
            COALESCE(LAG(x2, 2) OVER (ORDER BY t), 0) AS x2_lag2,
            COALESCE(LAG(x2, 3) OVER (ORDER BY t), 0) AS x2_lag3,
            COALESCE(LAG(x2, 4) OVER (ORDER BY t), 0) AS x2_lag4,
            COALESCE(LAG(x3, 1) OVER (ORDER BY t), 0) AS x3_lag1,
            COALESCE(LAG(x3, 2) OVER (ORDER BY t), 0) AS x3_lag2,
            COALESCE(LAG(x3, 3) OVER (ORDER BY t), 0) AS x3_lag3,
            COALESCE(LAG(x3, 4) OVER (ORDER BY t), 0) AS x3_lag4
        FROM public.my_time_series_table
    )
)
OPTIONS (
    'numVariables' -> '3',
    'numLags'      -> '4'
);
```

# Regression Models

Train and apply OcientML regression models in SQL, including linear and tree-based regressors, to predict numeric outcomes from labeled training data.

OcientML™ supports regression models that investigate the relationship between independent variables and at least one dependent variable or outcome. When trained, regression models can help establish the relationship between variables by estimating how one affects the other.

To create the model, use the `CREATE MLMODEL` syntax. For details, see **CREATE MLMODEL**.

## Regression Model Common Options

The regression model types have many common options that provide similar functionality. This table describes the purpose of the more common options.

| Option | Notes |
|---|---|
| `metrics` | The model supports the `metrics` option for all regression types. If this option is set to `true`, the model calculates $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC. The exception is Vector Autoregression, which calculates only $R^2$. The default value is `false`. |
| `threshold` | Most regression model types support the `threshold` option, which enables soft-thresholding. This model type is the same as lasso regression for simple linear regression. However, this model type is not quite the same as lasso regression for other model types. If you specify a non-zero threshold, the model shifts coefficients towards zero by the amount of the threshold. If this shift causes the coefficient to switch from positive to negative or vice versa, the model sets the coefficient to zero. The system performs this coefficient adjustment as a final step before the system saves the model coefficients. Any reported coefficient of determination is based on the model prior to adjustment. The adjustment always causes the coefficient of determination to be smaller. However, this approach is useful as it prevents overfitting. |
| `gamma` | Some regression model types support the `gamma` option. The value of this option is the Tikhonov square matrix in the form: `{{a, b, c, ...}, {d, e, f, ...}, {g, h, i, ...}}`. If you do not specify this option, the model defaults the option to the `0` matrix, which equates to multiple linear regression without regularization. You can perform ridge regression by using a `gamma` value. This is a bit complicated for the polynomial and linear combination regression model types. The system computes these model types by using multiple linear |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Option | Notes |
| --- | --- |
| | regression after applying the functions to be linearly combined to the input arguments. In these cases, the system applies ridge regression after applying the model functions to the model input values. |
| `weighted` | Some regression model types also support weighted least squares. The model types do not support generalized least squares, where the weight matrix can be non-diagonal. To use weighted least squares, add the option `weighted` and set it to `true`. Then, add one more column to the result set used to create the model. This new column must appear last, after the dependent variable, and it specifies the weight for that sample. |

Model option names are case-sensitive.

## Simple Linear Regression

Model Type: `SIMPLE LINEAR REGRESSION`

Trains a new machine learning model of type `<model_type>` on the result set returned by the SQL SELECT statement. After the database creates the model, `<model_name>` becomes an executable function in SQL SELECT statements.

SQL

```
CREATE MLMODEL model_name
    TYPE model_type ON (
        select_statement
)
    [ options( option_list ) ]
```

The result set used as input to the model must have two numeric columns. The first column is the independent variable (referred to as `x`). The second column is the dependent variable (referred to as `y`). The model finds the least squares best fit for `y = ax + b`.

The simple linear regression model type also supports the `yIntercept` option, which is the y-intercept of the resulting best-fit line. If you do not specify this option, the model does not force the y-intercept to be any particular value, and the model uses least squares to find the best value instead. If you force the y-intercept to be a particular value, the uses least squares to find the best fit with that constraint.

## Model Options

### Optional

`metrics` — If you set this option to `true`, the model calculates $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC. The default value is `false`.

`yIntercept` — If you set this option, then the option must be a numeric value. The system forces the specific y-intercept (i.e., the model value when `x` is zero).

`threshold` — This option enables soft thresholding. If you specify this option, then the option must be a positive numeric value. After the model calculates the coefficients, if any are greater than the threshold value, the threshold value is subtracted from them. If any coefficients are less than the negation of the threshold value, the model adds the threshold value to them. For any coefficients that are between the negative and positive threshold values, the model sets those coefficients to zero.

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. This option defaults to `true`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

## Execute the Model

Create a simple linear regression model with y-intercept `10`. Collect metrics for the model execution by setting the `metrics` option to `true`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE MLMODEL my_model
TYPE SIMPLE LINEAR REGRESSION ON (
  SELECT
    x1,
    y
  FROM public.my_table
)
options(
  'yIntercept' -> '10',
  'metrics' -> 'true'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model after training, the model takes a single numeric argument that represents `x` and returns `ax + b`.

SQL

```
SELECT my_model(col1) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.simple_linear_regression_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in **System Catalog**.

## Multiple Linear Regression

Model Type: `MULTIPLE LINEAR REGRESSION`

Multiple linear regression means that there is a vector of independent variables and the dependent variable is a scalar-valued function of the vector input, and that it is linear in all vector components.

The model uses the result set as an input. The result set has N columns that must be numeric. The first `N - 1` columns are the independent variables (it can be considered a single independent variable that is a vector). The last column is the dependent variable. The model finds the least squares best fit for `y = a1 * x1 + a2 * x2 + ... + b`, or in vector notation, `y = ax + b`, where `a` and `x` are vectors and the multiplication is a dot product.

## Model Options

### Optional

`metrics` — If you set this option to `true`, the model calculates $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC. The default value is `false`.

`threshold` — This option enables soft thresholding. If you specify this option, the option must be a positive numeric value. After the model calculates the coefficients, if any coefficients are greater than the threshold value, the model subtracts the threshold value from the coefficients. If any coefficients are less than the negation of the threshold value, the model adds the threshold value to the coefficients. For any coefficients that are between the negative and positive threshold values, the model sets the coefficients to zero.

`weighted` — If you set this option to `true`, the model performs weighted least squares regression, where each sample has a weight or importance associated with it. In this case, there is an extra numeric column after the dependent variable that has the weight for the sample. This option defaults to `false`.

`gamma` — If you set this option, the option must be a matrix. The value represents a Tikhonov gamma matrix used for regularization. For details, see **Tikhonov regularization**. The model uses this option for ridge regression.

`yIntercept` — If you set this option, then the option must be a numeric value. The system forces the specific y-intercept (i.e., the model value when `x` is zero).

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. This option defaults to `true`.

© 2026 Ocient, Inc

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

## Execute the Model

Create a multiple linear regression model. Collect metrics for the model execution by setting the `metrics` option to `true`.

SQL

```
CREATE MLMODEL my_model
TYPE MULTIPLE LINEAR REGRESSION ON (
  SELECT
    x1,
    x2,
    x3,
    y
  FROM public.my_table
)
options(
  'metrics' -> 'true'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model after training, the independent variables are provided to the model function execution, and the function returns the estimate of the dependent variable.

```SQL
SELECT my_model(col1, col2, col3) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.multiple_linear_regression_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in **System Catalog**.

## Vector Autoregression

Model Type: `VECTOR AUTOREGRESSION`

Vector auto-regression is a model that estimates the next value of multiple variables based on some number of lags of all variables, as a group. The model tries to build the following:

```Text
Estimate <x1(t), x2(t)> based on x1(t-1), x2(t-1), x1(t-2), and x2(t-2)
```

In this example, `x1(t)` means the value of `x1` at time `t`, and `x1(t-1)` means the value of `x1` at time `t-1` (typically the previous sample time). The syntax `<x1(t), x2(t)>` demonstrates that the result of the model is a row vector that contains all the predictions of the model and that all predictions rely on all lags of all variables.

When you create a model, the input result set must have one more column than the number of lags. Each column must be a row vector of a size equal to the number of variables. The first column is the un-lagged values, e.g., `{{x1, x2, x3}}`. The second column is the first lag for all variables, e.g., `{{x1_lag1, x2_lag2, x3_lag3}}`.

For functions to help organize data before training a model, see **Data Preparation**.

## Model Options

### Required

`numVariables` — Specify this option as a positive integer for the number of variables in the model.

`numLags` — Specify this option as a positive integer for the number of lags in the model.

### Optional

`metrics` — If you set this option to `true`, the model calculates $R^2$. The default value is `false`.

`threshold` — This option enables soft thresholding. If you specify this option, then the option must be a positive numeric value. After the model calculates the coefficients, if any of them are greater than the threshold value, the threshold value is subtracted from them. If any coefficients are less than the negation of the threshold value, the model adds the threshold value to them. For any coefficients that are between the negative and positive threshold values, the model sets those coefficients to zero.

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. This option defaults to `true`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

## Execute the Model

Create a vector autoregression model with three variables and four lags on each one. Collect metrics for the model execution by setting the `metrics` option to `true`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

The example uses the **LAG_VECTORS** function to generate lagged columns of matrices for the vector autoregression model.

SQL

```
CREATE MLMODEL my_model
TYPE VECTOR AUTOREGRESSION ON (
  SELECT
    {{x1, x2, x3}},
    LAG_VECTORS(x1, x2, x3, 1, 4) OVER(ORDER BY t)
  FROM public.my_table
)
OPTIONS(
  'metrics' -> 'true',
  'numVariables' -> '3',
  'numLags' -> '4'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model after training, the number of arguments you specify must be equal to the number of lags. Each of those arguments must be a lag vector that contains lagged values for all model variables at a specific lag period. The first argument to the model function ( `lag_vector_1` ) represents lag 1, the second argument ( `lag_vector_2` ) represents lag 2, and so on. The LAG_VECTORS function automatically generates these lag vectors with the appropriate structure.

In this example, lag 1 represents values from the previous row when ordered by time `t`, which means the model predicts the current values based on historical patterns from 1, 2, 3, and 4 rows back in the time-ordered sequence.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT my_model(lag_vector_1, lag_vector_2, lag_vector_3, lag_vector_4) AS predicte
    {{x1, x2, x3}} AS actual
FROM (
    SELECT x1, x2, x3,
        LAG_VECTORS(x1, x2, x3, 1, 4) OVER(ORDER BY t)
    FROM my_table
);
```

After you execute a model, you can find the details about the execution results in the `sys.vector_autoregression_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in **System Catalog**.

## Polynomial Regression

Model Type: `POLYNOMIAL REGRESSION`

Polynomial regression means that there is one to many independent variables and one dependent variable, and that should be modeled in terms of an nth-degree polynomial of the independent variables.

The `order` option must be set to a positive integer value that specifies the degree of the polynomial to use. If you specify the option `negativePowers` and set it to `true`, then the model also includes terms with negative exponents, but still with the restriction that the sum of the absolute value of the exponents in a term will be less than or equal to the value specified on the `order` option. Regardless of whether you use the `negativePowers` option, the model computes a coefficient for every possible term that meets this restriction. When you use the `negativePowers` option, the model contains many more terms. For example, a quadratic model over two independent variables has six terms, but when you use the `negativePowers` option, the model has 13 terms.

The result set you specify as input to the model has N columns, which must all be numeric. The first N-1 columns are the independent variables (it can be considered a single independent variable that is a vector). The last column is the dependent variable. The model finds the least squares best fit of a sum of all possible combinations of terms where the degree is less than or equal to the value of the order option. For example, with

two independent variables ( `x1` and `x2` ) and order set to 2, the model is `y = a1*x1^2 + a2*x2^2 + a3*x1*x2 + a4*x1 + a5*x2 + b`.

## Model Options

### Required

`order` — This option is the degree of the polynomial and must be set to a positive integer.

### Optional

`metrics` — If you set this option to `true`, the model calculates $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC. The default value is `false`.

`threshold` — This option enables soft thresholding. If you specify this option, then the option must be a positive numeric value. After the model calculates the coefficients, if any of them are greater than the threshold value, the threshold value is subtracted from them. If any coefficients are less than the negation of the threshold value, the model adds the threshold value to them. For any coefficients that are between the negative and positive threshold values, the model sets those coefficients to zero.

`weighted` — If you set this option to `true`, the model performs weighted least squares regression, where each sample has an associated weight. When weighted, there is an extra numeric column after the dependent variable that has the weight for the sample. This option defaults to `false`.

`negativePowers` — If you set this option to `true`, the model includes independent variables raised to negative powers. These variables are called Laurent polynomials. The model generates all possible terms such that the sum of the absolute value of the power of each term in each product is less than or equal to the order. For example, with two independent variables and the order set to 2, the model is: `y = a1*x1^2 + a2*x1^-2 + a3*x2^2 + a4*x2^-2 + a5*x1*x2 + a6*x1^-1*x2 + a7*x1*x2^-1 + a8*x1^-1*x2^-1 + a9*x1 + a10*x1^-1 + a11*x2 + a12*x2^-1 + b`.

`gamma` — If you specify this option, the value must be a matrix. The value represents a Tikhonov gamma matrix that is used for regularization. For details, see **Tikhonov regularization**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`yIntercept` — If you set this option, then the option must be a numeric value. The system forces the specific y-intercept (i.e., the model value when `x` is zero).

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. This option defaults to `true`.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

## Execute the Model

Create a polynomial regression model of degree 3. Collect metrics for the model execution by setting the `metrics` option to `true`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE MLMODEL my_model
TYPE POLYNOMIAL REGRESSION ON (
  SELECT
    x1,
    x2,
    x3,
    y
  FROM public.my_table
)
options(
  'order' -> '3',
  'metrics' -> 'true'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model after training, the independent variables are provided to the model function execution, and the function returns the estimate of the dependent variable.

SQL

```
SELECT my_model(col1, col2, col3) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.polynomial_regression_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in **System Catalog**.

## Linear Combination Regression

Model Type: `LINEAR COMBINATION REGRESSION`

Linear combination regression is a model built on top of m independent variables and a single dependent variable. But in this case, the function used to perform least-squares

regression is a linear combination of functions that you specify. The general form is `y = c0 + c1 * f1(x1, x2, ...) + f2(x1, x2, ...) + ...`.

The model determines the number of independent variables based on the number of columns in the SQL statement on which the model is based. There is always a column for the dependent variable, and there can be a weight column (see the `weighted` option). So, the number of independent variables is either one or two less than the number of columns in the result of the input SQL statement. The number of user-specified functions for the model must be specified by defining `function1`, `function2`, and so on (keys in the options dictionary). As long as consecutive function key names exist, the model includes these names. The model always includes a constant term. The value strings for the `functionN` keys must be specified in SQL syntax and should refer to `x1, x2, ...` for the model input independent variables.

The result set you specify as input to the model has N columns, which must all be numeric. The first N-1 columns are independent variables (it can be considered a single independent variable that is a vector). The last column is the dependent variable. The model finds the least squares best fit for a model of the form `y = a1 * f1(x1, x2, ... xn) + a2 * f2(x1, x2, ... xn) + ... + an * fn(x1, x2, ... nx)`, where `f1, f2, ..., fn` are functions that are provided in a required option.

> The system validates the user-specified functions during prediction time. If the function definition is invalid, the model throws an error during this time.

## Model Options

### Required

`functionN` — You must specify the first function (`f1`) using a key named `'function1'`. Subsequent functions must use keys with names that use subsequent values of N. You must specify functions in SQL syntax and should use the variables `x1, x2, ..., xn` to refer to the 1st, 2nd, and nth independent variables, respectively. For example, `'function1' -> 'sin(x1 * x2 + x3)', 'function2' -> 'cos(x1 * x3)'`.

### Optional

`metrics` — If you set this option to `true`, the model calculates $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC. The default value is `false`.

© 2026 Ocient, Inc

`threshold` — This option enables soft thresholding. If you specify this option, the option must be a positive numeric value. After the model calculates the coefficients, if any coefficients are greater than the threshold value, the model subtracts the threshold value from the coefficients. If any coefficients are less than the negation of the threshold value, the model adds the threshold value to the coefficients. For any coefficients between the negative and positive threshold values, the model sets the coefficients to zero.

`weighted` — If you set this option to `true`, the model performs weighted least squares regression, where each sample has an associated weight or importance. When weighted, there is an extra numeric column after the dependent variable that represents the weight of the sample. This option defaults to `false`.

`gamma` — If you specify this option, it must be a matrix. The value represents a Tikhonov gamma matrix used for regularization. For details, see **Tikhonov regularization**.

`yIntercept` — If you set this option, then the option must be a numeric value. The system forces the specific y-intercept (i.e., the model value when `x` is zero).

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. This option defaults to `true`.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

## Execute the Model

Create a linear combination regression with two functions that exhibit a wave-like pattern.

SQL

```
CREATE MLMODEL my_model
TYPE LINEAR COMBINATION REGRESSION
ON (
  SELECT
    x1,
    x2,
    x3,
    y1
  FROM public.my_table
)
options(
  'function1' -> 'sin(x1 * x2 + x3)',
  'function2' -> 'cos(x1 * x3)'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model after training, the independent variables are provided to the model function execution, and the function returns the estimate of the dependent variable.

SQL

```
SELECT my_model(col1, col2, col3) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.linear_combination_regression_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in **System Catalog**.

# Nonlinear Regression

Model Type: `NONLINEAR REGRESSION`

Nonlinear regression finds the best-fit parameters of an arbitrary function using an arbitrary loss function. This model type essentially provides direct access to capabilities that both logistic regression and support vector machines rely on. The first `N - 1` columns are numeric independent variables, and the last column is the numeric dependent variable.

> If you specify a function or loss function with an invalid value, the model throws an error from the `SELECT` statements at training time.

## Model Options

### Required

`numParameters` — Specify this option as a positive integer. This value specifies the number of different parameters to optimize, i.e., how many different `aN` variables there are in the user-specified function.

`function` — Specify the name of the function to fit the data in SQL syntax. Use `a1, a2, …` to refer to the parameters for optimization. Use `x1, x2, …` to refer to the input features. The model does not allow some SQL functions. The model allows only scalar expressions that can be represented internally as postfix expressions. Most notably, the model does not allow some functions that are rewritten as CASE statements (like `least()` and `greatest()`). If your function is not allowed, the model displays an error message.

This model does not perform auto-scaling.

### Optional

`metrics` — If you set this option to `true`, the model calculates $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC. However, the model calculates these quality metrics using the least squares loss function, and not the user-specified loss function, because these metrics really only make sense for least squares.

`lossFunction` — If you specify this option, this parameter dictates the nonlinear optimizer the loss function uses on a per-sample basis. Then, the actual loss function is

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

the sum of this function applied to all samples. The model should use the variable `y` to refer to the dependent variable in the training data and the variable `f` to refer to the computed estimate for a specified sample. The default is least squares, which could be specified as `(f-y)*(f-y)`.

`minInitParamValue` — A DOUBLE value setting the lower bound for random initial parameter values. The default value is -1.

`maxInitParamValue` — A DOUBLE value setting the upper bound for random initial parameter values. The default value is 1.

`ridgeCoefficient` — If you specify this option, the value must be a `double` data type. This option is the ridge coefficient for the loss function. The default behavior is that the function ignores this option, effectively setting this option to `0.0`.

`lassoCoefficient` — If you specify this option, the value must be a `double` data type. This option is the lasso coefficient for the loss function. The default behavior is that the function ignores this option, effectively setting this option to `0.0`.

`samplesPerThread` — If you specify this option, the value must be a positive integer. This parameter controls the target number of samples sent to each thread. Each thread independently computes a logistic regression model, and the models are all combined at the end. The option defaults to 1 million.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`finiteDifferenceH` — A `DOUBLE` value representing the step size (h) for approximating gradients using the finite difference method. The model uses this value only if analytical gradients are not active.

This value should generally be a small positive value, typically from 0.0001 (1e-4) to 0.0000001 (1e-7).

If you do not specify this value, the default is 0.00001 (1e-5).

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`skipDropTable` — If you set this option to `false` , the database deletes any intermediate tables created during model training. If you set this option to `true` , the database prevents the deletion of any intermediate tables created during model training. The default value is `false` .

## Execute the Model

Create a nonlinear regression that fits five parameters `a1, a2, a3, a4, a5` with two independent variables `x1, x2` .

SQL

```
CREATE MLMODEL my_model
TYPE NONLINEAR REGRESSION
ON (
  SELECT
    x1,
    x2,
    y1
  FROM public.my_table
)
options(
  'numParameters' -> '5',
  'function' -> 'a1 * sin(a2 * x1 + a3) + a4 + a5 * x2'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When the model executes, pass `N - 1` independent variables, and the model returns the estimate of the dependent variable.

```sql
SELECT my_model(x1, x2) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.nonlinear_regression_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in the **System Catalog**.

# Regression Tree

Model Type: `REGRESSION TREE`

Regression Tree is a supervised machine learning algorithm that predicts continuous numerical values by constructing a tree-like model, similar to how Decision Tree models work for classification. For details, see **Decision Tree (Classification)**.

A Regression Tree outputs continuous target values by learning simple decision rules inferred from the input features. The algorithm recursively splits the data set based on feature values that minimize prediction error (typically measured by mean squared or absolute error). Each internal node represents a decision based on a feature value, each branch represents the outcome of that decision, and each leaf node contains a predicted numerical value, typically the mean of the target values in that region.

The Regression Tree model is particularly effective for problems involving numerical prediction, such as price forecasting, demand estimation, or any scenario where the target variable is continuous rather than categorical.

## Model Options

### Optional

`continuousFeatures` — A set of INTEGER values specifying which input feature columns should be treated as continuous numeric variables for optimal tree splitting. The value must be a comma-separated list of feature column indexes (starting with 1) that

correspond to numeric columns in your SELECT statement, excluding the target column. For example, `'continuousFeatures' -> '1,2'` would treat the first and second columns of your SELECT statement as continuous. If not specified, all features are treated as categorical, which can impair results for numeric columns like prices, measurements, or scores.

`distinctCountLimit` — If you set this option, the value must be a positive integer. This value sets the limit for the number of distinct values a non-continuous feature and the label can contain. This option defaults to 256.

`maxCellsToFetch` — If you set this option, the value must be a positive integer. Controls the chunking behavior when fetching feature values during model training. The limit represents the maximum number of data cells (calculated as number of columns × number of rows) that can be fetched in a single operation, not a byte limit. When the expected data size exceeds this threshold, the algorithm switches to database-based processing using SQL queries instead of in-memory processing. This value defaults to 33,554,432 cells (calculated as 32 * 1024 * 1024).

`maxDepth` — If you set this option, the value must be a positive integer. This value sets the maximum allowable depth of the decision tree (the maximum number of features to split on). The default is unspecified, which means there is no maximum depth.

`maxRows` — If you set this option, the value must be a positive integer. This option limits the number of rows used for model training by creating a snapshot table with only the specified number of rows from the input query. When you do not set this option, the model trains using all rows from the input query.

`maxThreads` — If you set this option, the value must be a positive integer. This value indicates the maximum number of parallel threads to use while the model trains. The default value is 2.

`metrics` — If you set this option to `true`, the model calculates $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC. The default value is `false`.

`numSplits` — If you set this option, the value must be an integer greater than 1. This value sets the maximum number of binary branches a continuous feature can consider. The default value is 32.

`skipLimitCheck` — If you set this option to `true`, the model skips cardinality checks that throw errors when columns have too many values. The limit this option checks is the

same as the one specified by the `distinctCountLimit` option. The default value is `false`.

`enableResplits` — A Boolean value that determines if the tree can reuse the same continuous feature multiple times along a single branch (e.g., split on `x1 < 7` and later `x1 < 3`). This can capture more complex, range-specific relationships. If unspecified, this value defaults to true, meaning continuous features remain available for additional splits after use, allowing the tree to create more complex decision boundaries. When set to false, the model marks continuous features as exhausted after their first use, and they cannot be used again in subsequent splits in the same tree.

`resplitDepth` — An INTEGER value that sets the maximum depth at which tree nodes can be re-split during optimization. Controls how deep the algorithm searches for better split points. If unspecified, this value defaults to 6.

`resplitThreshold` — A DECIMAL value that sets the minimum improvement threshold required to trigger a re-split operation. Lower values (e.g. 0.01) allow more aggressive re-splitting but can increase training time. Higher values (e.g. 1.0) require larger improvements to trigger re-splits. If unspecified, this value defaults to 0.1.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`queryInternalParallelism` — If you set this option, the database appends the `USING PARALLELISM = <value>` clause to all intermediate SQL queries the model executes during training, where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

## Execute the Model

This example creates a regression tree model using three input features ( `feature1`, `feature2`, `feature3` ) to predict a continuous target variable. The model builds a single

tree structure that performs predictions by following a series of binary decisions based on feature values.

The model uses these options:

- `'maxDepth' -> '5'` — Limits the tree to a maximum depth of 5 levels, controlling model complexity and preventing overfitting. A depth of 5 provides a good balance between model expressiveness and generalization capability.
- `'enableResplits' -> 'true'` — Allows the algorithm to reuse the same continuous feature multiple times along a single branch path with different threshold values.

SQL

```
CREATE MLMODEL my_reg_tree
TYPE REGRESSION TREE
ON (
    SELECT feature1, feature2, feature3, target
    FROM training_data
)
OPTIONS (
    'maxDepth' -> '5',
    'enableResplits' -> 'true'
);
```

Call the trained model in a `SELECT` query, passing in the feature columns as arguments.

SQL

```
SELECT my_reg_tree(feature1, feature2, feature3)
FROM scoring_data;
```

For the output of the model, see the `sys.regression_tree_models` system catalog table.

## Gradient Boosted Trees

Model Type: `GRADIENT BOOSTED TREES`

Gradient Boosted Trees (GBT) is an ensemble machine learning algorithm that builds a sequence of decision trees where each new tree is trained to correct the prediction errors

of the previous trees. Unlike the Random Forest model, which creates trees independently in parallel, GBT uses a sequential approach based on gradient descent optimization, where each tree learns to predict the residual errors (gradients) of the current ensemble. This iterative error-correction process allows the model to capture complex, non-linear patterns by progressively refining predictions through multiple weak learners.

The algorithm supports both regression and classification tasks through different loss functions (use the `lossFunction` option to toggle whether the model performs regression or classification tasks). For regression with squared error loss, trees directly predict residual errors, while classification with logistic loss maintains raw scores transformed through sigmoid or softmax functions.

## Model Options

### Required

`numChildren` — An INTEGER value representing the total number of trees to build sequentially. Each tree learns to correct the errors of the previous trees.

`learningRate` — A DECIMAL value between 0.0 and 1.0 that tunes how much the model learns from each successive child.

### Optional

`lossFunction` — A string value that determines how the model calculates prediction errors and what type of problem it solves. Accepted values include:

- `'squared_error'` — Configures the model for regression tasks. Calculates errors as the squared difference between predicted and actual values. Use this for predicting continuous numeric values (e.g., prices, temperatures, quantities). The target column must contain numeric values. This is the default value.
- `'log_loss'` — Configures the model for classification tasks. This model uses logistic loss to calculate prediction errors for probability-based predictions.

`fractionSelected` — A DECIMAL value greater than 0.0 and less than or equal to 1.0 that specifies what fraction of the training rows to randomly select for each boosting iteration. When you specify a value, the algorithm uses `CEIL(fractionSelected * totalRows)` per iteration. If you do not specify this value, the model uses all rows in their original order.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`inputsPerChild` — An INTEGER greater than or equal to 1 that specifies the number of input features each boosting tree should use. This value cannot exceed the number of input features available in the data set. When you specify this value, the algorithm deterministically cycles through pre-enumerated feature subsets to ensure each tree uses exactly this many features. When you do not specify this value, the model uses all available features for each tree.

`maxDepth` — A positive INTEGER value that represents the maximum allowable depth of the decision trees. The default value is 3.

`maxThreads` — A positive INTEGER value that sets the maximum number of parallel threads to use for training each child decision tree. Parallel threads do not affect the sequential method of training each tree. The default value is 16.

`enableResplits` — A Boolean value that determines if the tree can reuse the same continuous feature multiple times along a single branch (e.g., split on `x1 < 7` and later `x1 < 3`). This action can capture more complex, range-specific relationships. If you do not specify this value, the default value is `true`, meaning continuous features remain available for additional splits after use, which allows the tree to create more complex decision boundaries. When you set this value to `false`, the model marks continuous features as exhausted after their first use, and the model cannot use these features again in subsequent splits in the same tree.

`resplitDepth` — An INTEGER value that sets the maximum depth at which tree nodes can be re-split during optimization. Controls how deep the algorithm searches for better split points. If you do not specify this value, the default value is 6.

`resplitThreshold` — A DECIMAL value that sets the minimum improvement threshold required to trigger a re-split operation. Lower values (e.g., 0.01) allow more aggressive re-splitting but can increase training time. Higher values (e.g., 1.0) require larger improvements to trigger re-splits. If you do not specify this value, the default value is 0.1.

`maxCellsToFetch` — An INTEGER value that determines the memory threshold to switch from training with system memory to training with SQL queries in the database. In-memory training is generally faster, but is limited by the available SQL Node memory. If the size of a training data subset exceeds this value, then the system performs training operations using SQL queries. The default value is 33,554,432 (calculated as `32 * 1024 * 1024`).

`metrics` — A Boolean value. If you set this value to `true`, the model calculates and stores quality metrics on the training data. For classification, the quality metrics include accuracy, confusion matrix, and MCC. The metrics also include per-class, macro, or weighted precision, recall, AUC-ROC, and F1 score. For regression, the quality metrics include $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC.

`featureArray` — A Boolean value. If you set this value to `true`, the model expects all input features to be in a single ARRAY column instead of separate columns.

`continuousFeatures` — A set of INTEGER values that specify the input feature columns that the model should treat as continuous numeric variables for optimal tree splitting. The value must be a comma-separated list of feature column indexes (starting with 1) that correspond to numeric columns in your `SELECT` SQL statement, excluding the target column. For example, `'continuousFeatures' -> '1,2'` would treat the first and second columns of your `SELECT` statement as continuous. If you do not specify this value, the model treats all features as categorical, which can impair results for numeric columns like prices, measurements, or scores.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

## Execute the Model

This example creates a GBT model to predict house prices using a sequential ensemble approach. The model trains on four input features ( `square_feet`, `bedrooms`, `bathrooms`, `age_years` ) to predict the target variable ( `price` ), filtering out any records with missing price data to ensure clean training.

The model uses these options:

- `'numChildren' -> '100'` — Builds a sequence of 100 regression trees. Each tree learns to correct the prediction errors made by all previous trees in the sequence. This relatively high number allows the model to capture complex patterns but requires careful tuning of the learning rate to prevent overfitting.
- `'learningRate' -> '0.1'` — Sets a conservative learning rate where each new tree contribution is scaled by 10 percent before being added to the ensemble. This moderate rate balances training speed with model stability.

- `'lossFunction' -> 'squared_error'` — Configures the model for regression by using squared error loss, which measures prediction accuracy as the squared difference between predicted and actual prices. This specification is the standard choice for continuous numeric predictions, ensuring the model optimizes for minimizing price prediction errors.

SQL

```
CREATE MLMODEL house_price_gbt
TYPE GRADIENT BOOSTED TREES
ON (
    SELECT square_feet, bedrooms, bathrooms, age_years, price
    FROM housing_data
    WHERE price IS NOT NULL
)
OPTIONS (
    'numChildren' -> '100',
    'learningRate' -> '0.1',
    'lossFunction' -> 'squared_error'
);
```

Call the trained model in a `SELECT` query, passing in the feature columns as arguments.

SQL

```
SELECT house_id,
    house_price_gbt(square_feet, bedrooms, bathrooms, age_years) AS predicted_price
FROM new_listings
WHERE square_feet IS NOT NULL
    AND bedrooms IS NOT NULL
    AND bathrooms IS NOT NULL
    AND age_years IS NOT NULL;
```

For the output of the model, see the `sys.gradient_boosted_trees_models` system catalog table.

# Classification Models

Train and use OcientML classification models such as decision trees, random forests, and naive Bayes in SQL to categorize data and detect patterns.

OcientML™ supports classification models that involve understanding and grouping large data sets into preset categories or subpopulations. With the help of pre-classified training data sets, machine learning classification models leverage various algorithms to classify future data sets into respective and relevant categories.

To create the model, use the `CREATE MLMODEL` syntax. For details, see **CREATE MLMODEL**.

> Model option names are case-sensitive.

## K-Nearest Neighbors Classification

Model Type: `K NEAREST NEIGHBORS`

K-nearest neighbors (KNN) is a classification algorithm, where the first `N - 1` inputs are the features, which must be numeric. The last input column is a label, which can be any data type.

There is no training step for KNN. Instead, when you create the model, the model saves a copy of all input data to a table, so that when the model is executed in a later SQL statement, a snapshot of the data the model is supposed to use is available. You can override both the weight function and the distance function.

> The system validates the `weight` and `distance` options during prediction time. If the values are invalid, the model throws an error during this time.

### Model Options

#### Required

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`k` — This option must be a positive integer that specifies how many closest points to use for classifying a new point.

## Optional

`distance` — If you specify this option, the value must be a function in SQL syntax for calculating the distance between a point used for classification and points in the training data set. This function should use the variables x1, x2, ... for the 1st, 2nd, ... features in the training data set, and p1, p2, ... for the features in the point for classification. If you do not specify this option, the option defaults to the Euclidean distance.

`metrics` — If you set this option to `true`, the model calculates accuracy, confusion matrix, and MCC. The model also calculates per-class, macro, or weighted precision, recall, and F1 score. The default value is `false`.

`normalize` — If you set this option to `true`, the model automatically computes the mean and standard deviation of each feature and uses them to normalize the data during training. The default value is `true`.

`weight` — If you specify this option, the value must be a function in SQL syntax for calculating the weight of a neighbor. The function should use the variable d for distance. By default, the distance is set to 1.0/(d+0.1), thus avoiding division by zero on exact inputs and still allowing neighbors to have some influence.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes

during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

## Execute the Model

Create a KNN model with `8` closest points for classification and distance function `power(x1 - p1, 2) + power(x2 - p2, 2) + power(x3 - p3, 2)`.

SQL

```
CREATE MLMODEL my_model
TYPE K NEAREST NEIGHBORS
ON (
  SELECT
    x1,
    x2,
    x3,
    y1
  FROM public.my_table
)
options(
  'k' -> '8',
  'distance' -> 'power(x1 - p1, 2) + power(x2 - p2, 2) + power(x3 - p3, 2)'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model, the model executes with `N - 1` features as input and returns a label. The model chooses the label from the class with the highest score. The model scores classes by summing the weights from the nearest k points in the training data.

SQL

```
SELECT my_model(x1, x2, x3) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.k_nearest_neighbors_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in the **System Catalog**.

# Naive Bayes Classification

Model Type: `NAIVE BAYES`

Naive Bayes is a classification algorithm. The input is `N - 1` feature columns, and the last column is a label column. All columns can be any data type. The label column must be discrete. The feature columns can be discrete or continuous. When you use continuous feature columns, you must specify which columns are continuous (see options).

Naive Bayes works by assuming that all features are equally important in the classification and that there is no correlation between features. With those assumptions, the algorithm computes all frequency information and saves it in three tables that you create using SQL `SELECT` statements.

## Model Options

### Optional

`metrics` — If you set this option to `true`, the model calculates accuracy, confusion matrix, and MCC. The model also calculates per-class, macro, or weighted precision, recall, and F1 score. The default value is `false`.

`continuousFeatures` — If you specify this option, the value must be a comma-separated list of the feature indexes that are continuous numeric variables. Indexes start at 1.

`normalize` — If you set this option to `true`, the model automatically computes the mean and standard deviation of each feature and uses them to normalize the data during training. Defaults to `true`.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in

the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

## Execute the Model

Create a Naive Bayes model with feature indexes `1,3` .

SQL

```
CREATE MLMODEL my_model
TYPE NAIVE BAYES
ON (
  SELECT
    x1,
    x2,
    x3,
    y1
  FROM public.my_table
)
options(
  'continuousFeatures' -> '1,3'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model, you specify `N - 1` feature input arguments, and the model returns the most likely class. The returned class is based on computing the class with the highest probability, given prior knowledge of the feature values. In other words, the class `y` has the highest value of `P(y | x1, x2, …, xn)`.

```sql
SELECT my_model(col1, col2, col3) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.naive_bayes_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in **System Catalog**.

## Decision Tree

Model Type: `DECISION TREE`

The decision tree is a classification model. The first `N - 1` input columns are features and can be any data type. All non-numeric features must be discrete and contain no more than the configured `distinctCountLimit` number of unique values. This limit is in place to prevent the internal model representation from growing too large. Numeric features are discrete by default and have the same limitation on the number of unique values, but they can be marked as continuous with the `continuousFeatures` option. For continuous features, the model builds the decision tree by dividing the values into two ranges instead of using discrete, unique values. The last input column is the label and can be any data type.

When you create the model, you specify all features first, and then specify the label as the last column in the result set.

You can use secondary indexes on discrete feature columns to greatly speed up the training of a decision tree model.

Ocient® supports a similar tree model for regression. For details, see **Regression Tree**.

## Model Options

### Optional

`continuousFeatures` — If you set this option, the value must be a comma-separated list of the feature indexes that are continuous numeric variables. Indexes start with 1. In the default state, the model considers no features as continuous.

`distinctCountLimit` — If you set this option, the value must be a positive integer. This value sets the limit for how many distinct values a non-continuous feature and the label can contain. This option defaults to 256.

`doPrune` — If you set this option to `true`, the model uses Pessimistic Error Pruning (PEP) to prune the tree after training. This option defaults to `false`.

`featureArrayElements` — If you set this option, the value must be a comma-separated list of the feature indexes. If you set the `featureArray` option to `true`, this list determines the elements of the arrays to use for training. By default, the model uses all elements.

`maxCellsToFetch` — If you set this option, the value must be a positive integer. Controls the chunking behavior when fetching feature values during model training. The limit represents the maximum number of data cells (calculated as number of columns × number of rows) that can be fetched in a single operation, not a byte limit. When the expected data size exceeds this threshold, the algorithm switches to database-based processing using SQL queries instead of in-memory processing. This value defaults to 33,554,432 cells (calculated as 32 * 1024 * 1024).

`maxDepth` — If you set this option, the value must be a positive integer. This value sets the maximum allowable depth of the decision tree (the maximum number of features to split on). The default is unspecified, which means there is no maximum depth.

`maxRows` — If you set this option, the value must be a positive integer. This option limits the number of rows the model uses for training by creating a snapshot table with only the specified number of rows from the input query. When you do not specify this option, the model trains using all rows from the input query.

`maxThreads` — If you set this option, the value must be a positive integer. This value indicates the maximum number of parallel threads to use while the model trains. The

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

default value is 2.

`metrics` — If you set this option to `true`, the model calculates accuracy, confusion matrix, and MCC. The model also calculates per-class, macro, or weighted precision, recall, AUC-ROC, and F1 score. The default value is `false`.

`numSplits` — If you set this option, the value must be an integer greater than 1. This value sets the maximum number of binary branches a continuous feature can consider. The default value is 32.

`ROCNumSamples` — If you set the option, you must also set the `metrics` option. This positive integer indicates the number of samples for the model to use for the area under the ROC curve. The default value is 10.

`skipLimitCheck` — If you set this option to `true`, the model skips cardinality checks that throw errors when columns have too many values. The limit that this option checks is the same one that is specified by the `distinctCountLimit` option. This option defaults to `false`.

`weighted` — If you set this option, the model considers weights for labels. If you set this option value to `true`, you must specify an additional column as a `double` in the training data for label weights. Rows with the same labels must have the same weights. If you set this value to `auto`, the model calculates weights automatically by weighting each label according to the ratio of the count of the most frequent label to the count of the specified label. As a result, the most frequent label has a weight of `1.0`, and the other label weights are higher. This option defaults to `false`, which means all labels have equal weight.

`splitMetric` — Controls which function is used to evaluate the quality of a split during tree construction. Supported options are:

- `gini_impurity` (default) — Measures impurity based on class distributions.
- `weighted_f1` — Uses class-frequency–weighted F1 score to guide splits.

`enableResplits` — A Boolean value that determines if the tree can reuse the same continuous feature multiple times along a single branch (e.g., split on `x1 < 7` and later `x1 < 3`). This can capture more complex, range-specific relationships. If unspecified, this value defaults to true, meaning continuous features remain available

for additional splits after use, allowing the tree to create more complex decision boundaries. When set to false, the model marks continuous features as exhausted after their first use, and they cannot be used again in subsequent splits in the same tree.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

## Execute the Model

Create a decision tree model with feature indexes `1,3`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE MLMODEL my_model
TYPE DECISION TREE ON (
  SELECT
    c1,
    c2,
    c3,
    y1
  FROM public.my_table
)
options(
  'continuousFeatures' -> '1,3'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model, you must specify the `N - 1` features as parameters. The model returns the expected label.

SQL

```
SELECT my_model(col1, col2, col3) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.decision_tree_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in **System Catalog**.

## Random Forest

Model Type: `RANDOM FOREST`

Random forest is a classification model consisting of multiple decision trees. The result consists of the most common label among the tree results and an array of pairs of

labels and their frequencies, sorted in descending order by frequency.

The model breaks ties in various ways depending on the type of label. For strings, the model uses lexicographic order (reverse of the usual alphabetic order), so `C` comes before `A`, for example. For Booleans, the model chooses `true` before `false`. For numeric types, the model chooses the largest number first.

When you call the model to make classification predictions, you can optionally use soft voting by adding an extra Boolean argument to the statement, e.g., `house(x, y, true)`. This extra argument must be a Boolean literal, either `true` (soft voting) or `false` (hard voting). If you do not specify this value, the default value is `false` (hard voting).

In soft voting, each decision tree reports a list of possible results and their confidence factors. The random forest model adds the confidence factors from the decision trees and normalizes them to add up to 1.0. The model sorts the results by descending confidence, then by descending values.

In hard voting, the model does not account for confidence factors. Each decision tree makes its own class prediction as a vote. The model selects the prediction with the most votes from the trees.

## Model Options

### Required

`numChildren` — Number of child decision trees.

### Optional

`bootstrap` — If you set this option to `true`, the model uses bootstrap sampling with replacement, meaning each tree in the random forest is trained on a random subset of the data (either the `rowsPerChild` or `fractionSelected` value sets the exact number of rows), and the same row can appear multiple times in each tree. If you set this option to `false`, this option does not use replacement, meaning each row can appear at most once per tree. The default value is `false`.

`continuousFeatures` — If you set this option, the value must be a comma-separated list of the feature indexes that are continuous numeric variables. Indexes start with 1.

© 2026 Ocient, Inc

`distinctCountLimit` — If you set this option, the value must be a positive integer. This value limits how many distinct values a non-continuous feature and the label can contain. The default value is 256.

`featureSubsetStrategy` — If you set this option, the model passes this option directly to the child decision trees to specify how many features each tree should consider at each split from the still-available features. When this value is higher, the model has higher accuracy and lower variance, but it takes longer to train.

You can specify this option either as an integer (e.g., `4`, meaning consider up to four features at each split) or one of three string values:

- `all` — Each tree checks every feature.
- `sqrt` — Each tree checks up to the square root of the total number of features.
- `one-third` — Each tree checks up to one-third of the total number of features.

The default value is `all`.

`fractionSelected` — The proportion of rows the model uses to train each decision tree. The value is a `double` that must be in the interval (0, 1]. You cannot set this option if you also set the `rowsPerChild` option to a positive value. The default behavior is that the model uses all available rows.

`inputsPerChild` — Number of features used to create each child decision tree. The default value is the number of features you specify for the forest divided by 3 and rounded up.

`maxCellsToFetch` — If you set this option, the value must be a positive integer. Controls the chunking behavior when fetching feature values during model training. The limit represents the maximum number of data cells (calculated as number of columns × number of rows) that can be fetched in a single operation, not a byte limit. When the expected data size exceeds this threshold, the algorithm switches to database-based processing using SQL queries instead of in-memory processing. This value defaults to 33,554,432 cells (calculated as 32 * 1024 * 1024).

`maxChildThreads` — An integer representing the maximum number of threads each child decision tree can use. If you do not specify this option, each child decision tree uses at most one thread, the default for decision trees.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`maxDepth` — If you set this option, the value must be a positive integer. This value sets the maximum allowable depth of the decision tree. The default value is 3.

`maxThreads` — The maximum number of parallel threads to use while the model trains decision trees. This value must be a positive integer. The default value is 16.

`metrics` — If you set this option to `true`, the model calculates accuracy, confusion matrix, and MCC. The model also calculates per-class, macro, or weighted precision, recall, and F1 score, as well as per-class, macro, or weighted AUC-ROC for the random forest. The model always sets this option to `false` for the child trees.

`requiredFeatures` — A comma-separated list of integers as strings representing specific features where the first feature has the value `1`. The model uses these features in every decision tree in the forest. The default behavior is that the decision tree in the forest can train on any feature that is in the list.

`rowsPerChild` — If you set this option to a positive integer, the number represents the number of rows (from a random sample) to use for each decision tree. If you set this option to 0, each child uses all available rows. The default value is 0. You cannot set this option to a positive value if you also set the `fractionSelected` option.

`skipLimitCheck` — If you set this option to `true`, the model skips cardinality checks that throw errors when columns have too many values. The limit that this option checks is the same one that is specified by the `distinctCountLimit` option. The default value is `false`.

`weighted` — If you set this option, the model considers weights for labels. If you set this option value to `true`, you must specify an additional column as a `double` in the training data for label weights. Rows with the same labels must have the same weights. If you set this value to `auto`, the model calculates weights automatically by weighting each label according to the ratio of the count of the most frequent label to the count of the specified label. As a result, the most frequent label has a weight of `1.0`, and the other label weights are higher. This option defaults to `false`, which means all labels have equal weight.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option,

the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

## Execute the Model

Create a random forest model with four child decision trees and two features randomly chosen by the model for each tree. The `training_table` table contains the training data set. Collect metrics for the model execution by setting the `metrics` option to `true`.

SQL

```
CREATE MLMODEL test_model
TYPE RANDOM FOREST
ON (
  SELECT *
  FROM public.training_table
)
options(
  'numChildren' -> '4',
  'inputsPerChild' -> '2'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models`, `sys.machine_learning_model_options`, and `sys.random_forest_models` system catalog tables.

Execute this model using three columns `a`, `b`, and `c`, from `large_table` table that contains the whole data set.

SQL

```
SELECT test_model(a, b, c) FROM large_table;
```

Optionally, you can execute the model using soft voting by including an extra Boolean argument.

SQL

```
SELECT test_model(a, b, c, true) FROM large_table;
```

The output of the model is a tuple containing the most common label as the first element. The second element is an array of tuples, where the first element is the label and the second is the frequency. The model sorts the array by frequency from highest to lowest, where the sum of frequencies is 1. When two labels have the same frequency, the model breaks the tie according to lexicographic order.

To retrieve the most common label, use `[]` with an index of 1, `[1]`, for example, `test_model(a,b,c)[1]`.

After you execute a model, you can find the results in the output of the model function execution.

For details, see the description of the associated system catalog tables in the Machine Learning section in **System Catalog**.

## Logistic Regression

Model Type: `LOGISTIC REGRESSION`

This model fits a logistic curve to the data across any number of classes greater than one.

The first `N - 1` inputs are features and must be numeric. Features can be one-hot encoded. The last input column is the class or label. You must have at least one non-NULL label in the result set for model creation. The model best fits the logistic curve using a negative log likelihood loss function. The model uses an algorithm that is a combination of particle swarm optimization, line search, and genetic algorithms to find the best-fit parameters.

## Model Options

### Optional

`metrics` — If you set this option to `true`, the model calculates accuracy, confusion matrix, and MCC. The model also calculates per-class, macro, or weighted precision, recall, F1 score, and AUC-ROC. The default value is `false`.

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. This option defaults to `true`.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes

during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

## Execute the Model

Create a logistic regression model. Collect metrics for the model execution by setting the `metrics` option to `true`.

SQL

```
CREATE MLMODEL my_model
TYPE LOGISTIC REGRESSION
ON (
  SELECT
    x1,
    x2,
    x3,
    y1
  FROM public.my_table
)
options(
  'metrics' -> 'true'
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute this model after training, you must specify the features as input and the label as the output. The label can be any data type.

SQL

```
SELECT my_model(col1, col2, col3) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.logistic_regression_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in the **System Catalog**.

# Support Vector Machine

Model Type: `SUPPORT VECTOR MACHINE`

Support Vector Machine (SVM) essentially finds a hypersurface (the hypersurface is a curve in two-dimensional space) that correctly splits the data into any number of classes greater than one and maximizes the margin around the hypersurface. By default, SVM finds a hyperplane to split the data (the hyperplane is a straight line in two-dimensional space). SVM uses a hinge loss function to balance the two objectives of finding a hyperplane with a wide margin while minimizing the number of incorrectly classified points.

The first `N - 1` input columns are the features and must be numeric. The last column is the label and can be any arbitrary type. You must have at least one non-NULL label in the result set for model creation.

## Model Options

### Optional

`metrics` — If you set this option to `true`, the model calculates accuracy, confusion matrix, and MCC. The model also calculates per-class, macro, or weighted precision, recall, AUC-ROC, and F1 score. This default value is `false`.

`regularizationCoefficient` — If you specify this option, the value must be a valid floating-point number. This option is used to control the balance of finding a wide margin and minimizing incorrectly classified points in the loss function. When this value is larger (and positive), it makes having a wide margin around the hypersurface more important relative to the incorrectly classified points. Because of how Ocient implements SVM, the values for this parameter are likely different from the values used in other common SVM implementations. This option defaults to 1.0 / 1000000.0.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`functionN` — By default, SVM uses a linear kernel. If you use a different kernel, you must provide a list of functions that are summed together, just like with linear combination regression. You must specify the first function using a key named 'function1'. Subsequent functions must use keys with names that use subsequent values of N. You must specify functions in SQL syntax and use the variables x1, x2, ..., xn to refer to the 1st, 2nd, and nth independent variables, respectively. You can specify the default linear kernel as: 'function1' → 'x1', 'function2' → 'x2', and so on. The model always adds a constant term equivalent to 'functionN' → '1.0' that you do not need to specify explicitly.

`normalize` — If you set this option to `true`, the model automatically computes the mean and standard deviation of each feature and uses them to normalize the data during training. Defaults to `true`.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

## Execute the Model

Create a support vector machine model.

```sql
CREATE MLMODEL my_model
TYPE SUPPORT VECTOR MACHINE ON (
  SELECT
    c1,
    c2,
    c3,
    y1
  FROM public.my_table
);
```

After you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model, the `N - 1` features must be passed as parameters. The model returns the expected label.

```sql
SELECT my_model(col1, col2, col3) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.support_vector_machine_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in the **System Catalog**.

## Gradient Boosted Trees

Model Type: `GRADIENT BOOSTED TREES`

Gradient Boosted Trees (GBT) is an ensemble machine learning algorithm that builds a sequence of decision trees where each new tree is trained to correct the prediction errors of the previous trees. Unlike the Random Forest model, which creates trees independently in parallel, GBT uses a sequential approach based on gradient descent optimization, where each tree learns to predict the residual errors (gradients) of the

current ensemble. This iterative error-correction process allows the model to capture complex, non-linear patterns by progressively refining predictions through multiple weak learners.

The algorithm supports both regression and classification tasks through different loss functions (use the `lossFunction` option to toggle whether the model performs regression or classification tasks). For regression with squared error loss, trees directly predict residual errors, while classification with logistic loss maintains raw scores transformed through sigmoid or softmax functions.

## Model Options

### Required

`numChildren` — An INTEGER value representing the total number of trees to build sequentially. Each tree learns to correct the errors of the previous trees.

`learningRate` — A DECIMAL value between 0.0 and 1.0 that tunes how much the model learns from each successive child.

### Optional

`lossFunction` — A string value that determines how the model calculates prediction errors and what type of problem it solves. Accepted values include:

- `'squared_error'` — Configures the model for regression tasks. Calculates errors as the squared difference between predicted and actual values. Use this for predicting continuous numeric values (e.g., prices, temperatures, quantities). The target column must contain numeric values. This is the default value.
- `'log_loss'` — Configures the model for classification tasks. This model uses logistic loss to calculate prediction errors for probability-based predictions.

`fractionSelected` — A DECIMAL value greater than 0.0 and less than or equal to 1.0 that specifies what fraction of the training rows to randomly select for each boosting iteration. When you specify a value, the algorithm uses `CEIL(fractionSelected * totalRows)` per iteration. If you do not specify this value, the model uses all rows in their original order.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`inputsPerChild` — An INTEGER greater than or equal to 1 that specifies the number of input features each boosting tree should use. This value cannot exceed the number of input features available in the data set. When you specify this value, the algorithm deterministically cycles through pre-enumerated feature subsets to ensure each tree uses exactly this many features. When you do not specify this value, the model uses all available features for each tree.

`maxDepth` — A positive INTEGER value that represents the maximum allowable depth of the decision trees. The default value is 3.

`maxThreads` — A positive INTEGER value that sets the maximum number of parallel threads to use for training each child decision tree. Parallel threads do not affect the sequential method of training each tree. The default value is 16.

`enableResplits` — A Boolean value that determines if the tree can reuse the same continuous feature multiple times along a single branch (e.g., split on `x1 < 7` and later `x1 < 3`). This action can capture more complex, range-specific relationships. If you do not specify this value, the default value is `true`, meaning continuous features remain available for additional splits after use, which allows the tree to create more complex decision boundaries. When you set this value to `false`, the model marks continuous features as exhausted after their first use, and the model cannot use these features again in subsequent splits in the same tree.

`resplitDepth` — An INTEGER value that sets the maximum depth at which tree nodes can be re-split during optimization. Controls how deep the algorithm searches for better split points. If you do not specify this value, the default value is 6.

`resplitThreshold` — A DECIMAL value that sets the minimum improvement threshold required to trigger a re-split operation. Lower values (e.g., 0.01) allow more aggressive re-splitting but can increase training time. Higher values (e.g., 1.0) require larger improvements to trigger re-splits. If you do not specify this value, the default value is 0.1.

`maxCellsToFetch` — An INTEGER value that determines the memory threshold to switch from training with system memory to training with SQL queries in the database. In-memory training is generally faster, but is limited by the available SQL Node memory. If the size of a training data subset exceeds this value, then the system

performs training operations using SQL queries. The default value is 33,554,432 (calculated as `32 * 1024 * 1024`).

`metrics` — A Boolean value. If you set this value to `true`, the model calculates and stores quality metrics on the training data. For classification, the quality metrics include accuracy, confusion matrix, and MCC. The metrics also include per-class, macro, or weighted precision, recall, AUC-ROC, and F1 score. For regression, the quality metrics include $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC.

`featureArray` — A Boolean value. If you set this value to `true`, the model expects all input features to be in a single ARRAY column instead of separate columns.

`continuousFeatures` — A set of INTEGER values that specify the input feature columns that the model should treat as continuous numeric variables for optimal tree splitting. The value must be a comma-separated list of feature column indexes (starting with 1) that correspond to numeric columns in your `SELECT` SQL statement, excluding the target column. For example, `'continuousFeatures' -> '1,2'` would treat the first and second columns of your `SELECT` statement as continuous. If you do not specify this value, the model treats all features as categorical, which can impair results for numeric columns like prices, measurements, or scores.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

## Execute the Model

This example creates a Gradient Boosted Trees classifier to predict whether a customer stops using a service. The model trains on four input features ( `tenure_months`, `monthly_charges`, `total_charges`, `support_tickets` ) to predict the target variable ( `churn_label` ), filtering out any records with missing labels to ensure clean training.

The model uses these options:

- `'numChildren' -> '100'` — Builds a sequence of 100 weak learners (regression trees). Each tree learns to correct the classification residuals (logistic loss) of all

previous trees. A higher value can capture complex patterns, and you should pair it with an appropriate learning rate.

- `'learningRate' -> '0.1'` — Scales the contribution of each new tree by 10 percent, balancing convergence speed and generalization. This value represents a small learning rate, making training more conservative and stable.
- `'lossFunction' -> 'log_loss'` — Configures the model for classification through logistic loss. If you do not specify this value, the default value is `'squared_error'` (regression), so explicitly setting `'log_loss'` is mandatory for classifiers.

SQL

```
CREATE MLMODEL churn_gbt_classifier
TYPE GRADIENT BOOSTED TREES
ON (
    SELECT
        tenure_months,
        monthly_charges,
        total_charges,
        support_tickets,
        churn_label
    FROM customer_training
    WHERE churn_label IS NOT NULL
)
OPTIONS (
    'numChildren'   -> '100',
    'learningRate'  -> '0.1',
    'lossFunction'  -> 'log_loss'
);
```

Call the trained model in a `SELECT` query, passing in the feature columns as arguments.

SQL

```sql
SELECT
    customer_id,
    churn_gbt_classifier(
        tenure_months,
        monthly_charges,
        total_charges,
        support_tickets
        )[1] AS predicted_label,
    churn_gbt_classifier(
        tenure_months,
        monthly_charges,
        total_charges,
        support_tickets
        )[2] AS class_probabilities
FROM customer_scoring
WHERE tenure_months IS NOT NULL
    AND monthly_charges IS NOT NULL
    AND total_charges IS NOT NULL
    AND support_tickets IS NOT NULL;
```

For classification, the model returns a tuple of:

- `element [1]` — The predicted class label
- `element [2]` — An array of ( `class_label` , `probability` ) pairs

For the output of the model, see the `sys.gradient_boosted_trees_models` system catalog table.

# Clustering and Dimension Reduction Models

Train and apply OcientML clustering and dimensionality reduction models including k-means and PCA, with SQL syntax, model options, and example queries.

OcientML™ supports these machine learning models for clustering and dimension reduction.

To create the model, use the `CREATE MLMODEL` syntax. For details, see **CREATE MLMODEL**.

> Model option names are case-sensitive.

## Principal Component Analysis

Model Type: `PRINCIPAL COMPONENT ANALYSIS`

Principal Component Analysis (PCA) is typically not used as a model on its own. PCA is most commonly used on the inputs to other models. PCA serves two purposes.

1. PCA normalizes all numeric feature data. Some types of models are sensitive to the scale of numeric features, and when different features have different scales, the results end up skewed. PCA normalizes all features to the same scale.
2. PCA is used for dimensionality reduction. PCA computes linear combinations of the original features to put the most signal into a smaller number of new features.

The input result set when creating a PCA model is N numeric columns, which are all features. There is no label or dependent variable. After you create a PCA model, the `sys.principal_component_analysis_models` system catalog table contains information on the percentage of the signal in each PCA feature. You can use this information to figure out how many of the output features to keep.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Also, after you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

## Principal Component Analysis and Logistic Regression

You can also use PCA models as inputs to other models. For example, if you have three features and you want to use PCA to reduce the number to two features, you can execute the following SQL statements.

SQL

```
CREATE MLMODEL reduceTo2
TYPE PRINCIPAL COMPONENT ANALYSIS ON (
  SELECT
    c1,
    c2,
    c3
  FROM public.my_table
);
```

You can use this model as input for another model, for example, logistic regression.

SQL

```
CREATE MLMODEL binaryClass
TYPE LOGISTIC REGRESSION ON (
  SELECT
    reduceTo2(c1, c2, c3, 1),
    reduceTo2(c1, c2, c3, 2),
    label
  FROM …
);
```

To correctly use this model later, you must pass the original features through the PCA model when you execute the logistic regression model.

```sql
SELECT
  binaryClass(
    reduceTo2(x1, x2, x3, 1),
    reduceTo2(x1, x2, x3, 2)
  )
FROM … ;
```

Similarly, to create a PCA analysis over four variables, execute this SQL statement:

```sql
CREATE MLMODEL my_model
TYPE PRINCIPAL COMPONENT ANALYSIS ON (
  SELECT
    c1,
    c2,
    c3,
    c4
  FROM public.my_table
);
```

## Model Options

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes

during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

# K-Means Clustering

Model Type: `KMEANS`

K-means is an unsupervised clustering algorithm. All of the columns in the input result set are features, and there is no label. All the input columns must be numeric. The algorithm finds `k` points such that all points are classified by the closest `k` points. Distance calculations are Euclidean by default.

## Model Options

### Required

`k` — This option must be a positive integer. The option specifies the algorithm for how many clusters to make.

### Optional

`epsilon` — If you specify this option, the value must be a valid positive floating point value. When the maximum distance that a centroid moves from one iteration of the algorithm to the next is less than this value, the algorithm terminates. This parameter defaults to `1e-4`.

`metrics` — If you set this option to `true`, the model calculates WCSS (Within-Cluster Sum of Squares), which measures the sum of squared distances of samples to their closest cluster center. The default value is `false`.

`normalize` — If you set this option to `true`, the model normalizes the data before the start of training. The default value is `true`.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

## Execute the Model

Create a K-means model with `8` clusters.

SQL

```
CREATE MLMODEL my_model
TYPE KMEANS
ON (
  SELECT
    x1,
    x2,
    x3,
    x4
  FROM public.my_table
)
options(
  'k' -> '8'
);
```

Also, after you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

Because there are no labels for clusters, when you execute this function after training with the same number (and same order) of features as input, the result is an integer that specifies the cluster to which the point belongs.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

```sql
SELECT my_model(x1, x2, x3, x4) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.k_means_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in the **System Catalog**.

# Gaussian Mixture

Model Type: `GAUSSIAN MIXTURE MODEL`

Gaussian Mixture Models (GMMs) find the mixture of `N` Gaussian distributions that best fit the data. The most common use is unsupervised clustering, but there are some key differences compared to K-means clustering:

- GMMs can handle clusters that are not circular, i.e., clusters in the shape of ovals or higher-dimensional analogs with variances in different directions.
- Clusters can have an arbitrary rotation, i.e., they can have covariance.
- GMMs can handle instances when clusters are not as equally likely. If a point is right between two clusters, it is more likely to be more common in the training data.
- GMMs can show the probability of a new point belonging to each cluster instead of providing only a single cluster value.

GMMs generally handle more complex data than K-means models, but they require more training and processing time during execution.

## Model Options

### Required

`numDistributions` — Must be a positive integer. This value specifies the number of clusters of Gaussian distributions for the model to make.

### Optional

`epsilon` — If you specify this option, the value must be a valid positive floating point value. When the maximum distance that the entire best model moves in its n-dimensional space is less than this value, the algorithm terminates. This parameter defaults to 1e-8 (0.00000001 as a decimal number).

`metrics` — If you set this option to `true`, the model calculates the log-likelihood of the data given the model. The default value is `false`.

`normalize` — If you set this option to `true`, the model automatically computes the mean and standard deviation of each feature and uses them to normalize the data during training. Defaults to `true`.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

## Execute the Model

Create a GMM with three clusters of Gaussian distributions.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE MLMODEL gmm
TYPE GAUSSIAN MIXTURE MODEL
ON (
  SELECT
    x,
    y,
    z
  FROM my_table
)
options(
  'numDistributions' -> '3'
);
```

Also, after you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute this function after training with the same number (and same order) of features as input, the result is an integer that specifies the probable cluster to which the point belongs.

SQL

```
SELECT gmm(x,y,z) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.gaussian_mixture_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in the **System Catalog**.

## Linear Discriminant Analysis

Model Type: `LINEAR DISCRIMINANT ANALYSIS`

Linear Discriminant Analysis (LDA) is a dimension-reduction technique similar to PCA. While PCA is unsupervised, LDA can classify and use class labels to find linear combinations of features that best separate the classes.

The input result set when you create an LDA model is `N` numeric columns that are all features. The last column is a class label and can be any data type. After you create an LDA model, the `sys.linear_discriminant_analysis_models` system catalog table contains information on the percentage of the signal that is in each LDA feature. You can use this information to figure out how many of the output features to keep.

Also, after you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

## Linear Discriminant Analysis and Logistic Regression

You can use LDA models as inputs to other models. For example, to reduce the number of features from three to two using LDA, you can execute these SQL statements.

SQL

```
CREATE MLMODEL reduceTo2
TYPE LINEAR DISCRIMINANT ANALYSIS ON (
  SELECT
    c1,
    c2,
    c3,
    label
  FROM public.my_table
);
```

You can use this model as input for another model, for example, logistic regression.

© 2026 Ocient, Inc

SQL

```
CREATE MLMODEL binaryClass
TYPE LOGISTIC REGRESSION ON (
  SELECT
    reduceTo2(c1, c2, c3, 1),
    reduceTo2(c1, c2, c3, 2),
    label
  FROM …
  );
```

To correctly use this model later, you must pass the original features through the LDA model when you execute the logistic regression model.

SQL

```
SELECT
  binaryClass(
    reduceTo2(x1, x2, x3, 1),
    reduceTo2(x1, x2, x3, 2)
  )
FROM … ;
```

Similarly, to create an LDA model over four variables, execute this SQL statement.

SQL

```
CREATE MLMODEL my_model
TYPE LINEAR DISCRIMINANT ANALYSIS ON (
  SELECT
    c1,
    c2,
    c3,
    c4,
    label
  FROM public.my_table
);
```

## Model Options

`normalize` — If you set this option to `true`, the model automatically computes the mean and standard deviation of each feature and uses them to normalize the data during training. Defaults to `true`.

`featureArray` — If you set this option to `true`, the model expects only one array-type column as input instead of multiple columns of training data. Each array row in the input column must be of the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

### Execute the Model

When you execute the trained LDA model, you must provide the same original input features in the same order, followed by a positive integer argument that specifies the LDA component to return. The LDA component index starts at 1.

SQL

```sql
SELECT
  my_model(col1, col2, col3, col4, 2) as component2,
  my_model(col1, col2, col3, col4, 3) as component3,
FROM public.my_table;
```

# Ensemble Models

Learn how OcientML ensemble models (Bagging, Boosting, Stacking) combine base models to reduce errors and improve predictions, with SQL syntax and examples.

Ensemble models improve predictive performance by combining the strengths of multiple individual machine learning models into a single, robust system. Instead of relying on one algorithm, ensemble techniques train a collection of base models and aggregate their predictions to reduce errors, lower variance, and prevent overfitting.

## Bagging

Model Type: `BAGGING`

A bagging model trains multiple base models in parallel on random subsets of the training data and aggregates their predictions. Use the bagging model to reduce variance and prevent overfitting.

The bagging model utilizes child models embedded as options in JSON format (see `baseModels`).

The bagging model trains all child models independently in parallel. When aggregating all the child model predictions, the bagging model uses majority voting for classification and averaging for regression.

> A bagging model can use any model type that supports classification or regression.

### Model Options

#### Required

`baseModels` — A JSON array defining the child models to train. Each object in the array specifies a model type, a count (how many of this model to create), and any options specific to the individual child model.

#### `baseModels` JSON Arguments

| Argument | Data Type | Description |
|---|---|---|
| `type` | string | The OcientML™ model type (e.g., `"DECISION TREE"`, `"MULTIPLE LINEAR REGRESSION"`).<br><br>The selected model type should comply with the selected `taskType` (i.e., select a classification model if your `taskType` is `CLASSIFICATION`. |
| `count` | integer | The number of instances of this model type to train. |
| `options` | JSON object | JSON object containing options specific to that child model type, exactly as if you were creating that model directly. For a list of supported options, see the descriptions of model types. |

`taskType` — Specifies the task type with values: `'CLASSIFICATION'` or `'REGRESSION'`.

## Optional

`maxThreads` — An optional integer value that controls the maximum number of child models that the bagging model trains in parallel. This option does not affect the internal threading of each child. If supported, the `maxThreads` value of each child model controls the internal threading. The default value is 16.

`bootstrap` — An optional Boolean value. If you set this option to `true`, the model uses bootstrap sampling with replacement. Each child trains on a random sample where rows can be repeated. If you set this option to `false`, the model uses sampling without replacement (each row appears at most one time per child). The default value is `false`.

`rowsPerChild` — An optional integer specifying the exact number of rows to use for each child model. `0` means use all available rows (only valid if you do not set the `fractionSelected` option). The default value is `0`.

`fractionSelected` — An optional double value between 0.0 and 1.0 that specifies the proportion of rows to use for each child model. This option is unusable if you set the `rowsPerChild` option to greater than 0. The default value is `1.0` (use all rows).

`inputsPerChild` — An optional integer that specifies the number of features (columns) to use for each child model. The default value is `CEIL(total_features / 3)`.

`metrics` — An optional Boolean value. If you set this option to `true`, the model calculates and stores quality metrics on the training data after training completes. The

default value is `false`.

For classification, the quality metrics include accuracy, confusion matrix, and MCC. The metrics also include per-class, macro, or weighted precision, recall, AUC-ROC, and F1 score.

For regression, the quality metrics include $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`featureArray` — An optional Boolean value. If you set this option to `true`, the model expects only one array-type column as input, rather than multiple columns of training data. Each array row in the input column must be the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

## Execute the Model

This example creates a bagging model that, in effect, functions as a random forest by training 50 decision trees for a classification task.

© 2026 Ocient, Inc

SQL

```
CREATE MLMODEL my_schema.bagging_classifier
TYPE BAGGING
OPTIONS (
    'taskType' = 'CLASSIFICATION',
    'baseModels' = '[
        {
            "type": "DECISION TREE",
            "count": 50,
            "options": {
                "maxDepth": 8,
                "splitMetric": "gini_impurity"
            }
        }
    ]',
    'bootstrap' = 'true',
    'fractionSelected' = '0.8',
    'maxThreads' = '16',
    'metrics' = 'true'
)
AS
SELECT
    feature1,
    feature2,
    feature3,
    label
FROM my_schema.training_data;
```

After the training completes, execute the bagging model.

SQL

```
SELECT
    my_schema.bagging_classifier(feature1, feature2, feature3)
FROM my_schema.scoring_data;
```

## Boosting

Model Type: `BOOSTING`

A boosting model is an ensemble technique that trains multiple base models sequentially, where each new model attempts to correct the errors of the combined previous models. Boosting reduces bias and errors in supervised learning tasks.

The boosting model utilizes child models specified as options in JSON format (see the `baseModels` argument). The boosting model trains its child models one after another, with each child contributing to the final prediction, weighted by a set learning rate.

> A boosting model can use any model type that supports regression.

## Model Options

### Required

`baseModels` — A JSON array describing the child models to train. Each object in the array specifies a model type, the number of instances of this model to create, and other options that depend on the model type.

#### `baseModels` JSON Arguments

| Argument | Data Type | Description |
|---|---|---|
| `type` | string | The OcientML model type (e.g., `"DECISION TREE"`, `"MULTIPLE LINEAR REGRESSION"`).<br><br>The selected model type should comply with the selected `taskType` (i.e., select a classification model if your `taskType` is `CLASSIFICATION`. |
| `count` | integer | The number of instances of this model type to train sequentially. |
| `options` | JSON object | JSON object containing options specific to that child model type, similar to creating that model directly. For a list of supported options of a child model, see the individual descriptions of model types. |

`taskType` — Specifies the task type with values: `'CLASSIFICATION'` or `'REGRESSION'`.

`learningRate` — A decimal value between 0.0 and 1.0 that tunes how much the model learns from each successive child. Lower values can lead to better generalization, but they require more trees (a higher `count` value in the `baseModels` JSON field).

© 2026 Ocient, Inc

## Optional

`lossFunction` — A string value that determines how the model calculates prediction errors and what type of problem it solves. Accepted values are:

- `'squared_error'` — Configures the model for regression tasks. Calculates errors as the squared difference between predicted and actual values. Use this value for predicting continuous numeric values (e.g., prices, temperatures, quantities). The target column must contain numeric values. The `lossFunction` option defaults to `squared_error` if you set the `taskType` option to `REGRESSION`.
- `'log_loss'` — Configures the model for classification tasks. This model uses logistic loss to calculate prediction errors for probability-based predictions. The `lossFunction` option defaults to `log_loss` if you set the `taskType` option to `CLASSIFICATION`.

`fractionSelected` — A double value specifying the proportion of rows ($0.0 < n <= 1.0$) to use for each child model. The default value is `1.0` (use all rows).

`inputsPerChild` — An integer value specifying the number of features (columns) to use for each child model. When you set this option, the algorithm deterministically cycles through feature subsets. If you do not set this option, the model uses all available features for each child.

`maxThreads` — An optional integer value that controls the maximum number of child models that the model trains in parallel. This option does not affect the internal threading of each child. If supported, the `maxThreads` value of each child model controls the internal threading. The default value is 16.

`metrics` — An optional Boolean value. If you set this option to `true`, the model calculates and stores quality metrics on the training data after training completes. The default value is `false`.

For classification, the quality metrics include accuracy, confusion matrix, and MCC. The metrics also include per-class, macro, or weighted precision, recall, AUC-ROC, and F1 score.

For regression, the quality metrics include $R^2$, adjusted $R^2$, RMSE, MAE, MAPE, AIC, and BIC.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`skipDropTable` — An optional Boolean value. If you set this option to `false`, the database deletes intermediate tables created during training. If you set this option to `true`, the database prevents deletion of intermediate tables (useful for debugging). The default value is `false`.

`continuousFeatures` — An optional comma-separated list of feature indexes (1-based) that are continuous numeric variables (i.e., not categorical or discrete variables).

`featureArray` — An optional Boolean value. If you set this option to `true`, the model expects only one array-type column as input, rather than multiple columns of training data. Each array row in the input column must be the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

## Execute the Model

This example creates a boosting model (similar to Gradient Boosted Trees but using generic boosting logic) that trains 100 decision trees sequentially for a regression task.

© 2026 Ocient, Inc

SQL

```
CREATE MLMODEL my_schema.boosting_regressor
TYPE BOOSTING
OPTIONS (
    'taskType' = 'REGRESSION',
    'baseModels' = '[
        {
            "type": "DECISION TREE",
            "count": 100,
            "options": {
                "maxDepth": 4
            }
        }
    ]',
    'learningRate' = '0.1',
    'lossFunction' = 'squared_error',
    'metrics' = 'true'
)
AS
SELECT
    feature1,
    feature2,
    feature3,
    label
FROM my_schema.training_data;
```

After training completes, execute the boosting model.

SQL

```
SELECT
    my_schema.boosting_regressor(feature1, feature2, feature3)
FROM my_schema.scoring_data;
```

## Stacking

Model Type: `STACKING`

The stacking model combines multiple base models into a single, higher-accuracy ensemble. A stacking model can use any other machine learning model that supports

regression, classification, or clustering.

A stacking model can produce better accuracy than a single model by incorporating the strengths of different models and feature subsets.

Stacking trains two model levels:

- Level-zero models: one or more base models that train on the original features.
- Level-one model (meta-model): a single model that trains on the predictions of the level-zero models (plus any preserved features), and learns how to weight and combine them.

> A stacking model cannot use the Vector Autoregression, Feedforward Neural Network, or Association Rules models as level-zero or level-one models.

## Model Options

### Required

The stacking model utilizes other models embedded as options in JSON format (see `levelZeroModels` and `levelOneModel`). Both are required.

`levelZeroModels` — An array of JSON objects representing one or more base models. Internally, the system maps these models using the same strings as other machine learning model types. Any stacked models have the same features, requirements, and options as they would without stacking.

`levelOneModel` — A JSON object that defines the single meta-model that sits on top of all level-zero models in a stacking ensemble. The object specifies the model type, name, and any model-specific options for this level-one model, which is trained on the outputs of the level-zero models (and any preserved input columns) to produce the final prediction.

JSON strings for both `levelZeroModels` and `levelOneModel` share these arguments unless noted otherwise in the description.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Argument | Data Type | Description |
|---|---|---|
| `type` | string | The machine learning model type to use for this child (for example, `"RANDOM FOREST"`, `"LOGISTIC REGRESSION"`, `"KMEANS"`). Must be a valid OcientML model type that supports regression, classification, or clustering. |
| `name` | string | Optional. A name for the child model. If you omit this argument, the system auto-generates a name by attaching a suffix to the parent model name. |
| `options` | JSON object | JSON object containing options specific to the chosen model type, exactly as if you were creating that model directly. For a list of options, see the individual descriptions of individual model types. |
| `ignoreColumns` | string | Optional. Used only for `levelZeroModels`. The value is a comma-separated list of 1-based column indices to exclude from this level-0 model training input. If you omit this argument, the model sees all available features, labels, and extra columns. |
| `extraCallArguments` | string | Advanced optional argument. An array of argument lists. Each element is an array of strings representing extra literal arguments appended when the system executes this child model in the level-one training SQL.<br><br>Level-zero child models can use any number of argument lists. Level-one child models can use only one argument list. |

## Optional

`maxThreads` — An optional integer value that controls the maximum number of level-0 child models that the stacking model trains in parallel. This option does not affect the internal threading of each child. If supported, the `maxThreads` value of each child model controls the internal threading. A higher `maxThreads` value can reduce total training time for many level-0 models, but increases concurrent resource usage on the cluster. The default value is 16.

`featureArray` — An optional Boolean value. If you set this option to `true`, the model expects only one array-type column as input, rather than multiple columns of training data. Each array row in the input column must be the same size. Regardless of whether you use this option, the model treats training data the same with labeling and weight scoring. The default value is `false`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`hasLabelColumn` — Specifies whether the training data includes a label column (necessary for supervised tasks like classification or regression). If you set this option to `true`, the input query must return features followed by a label column. If you set this option to `false`, the model assumes the input contains only features (typically for unsupervised tasks, such as clustering or dimension reduction models). The default value is `true`.

`extraColumnCount` — A non-negative integer representing the number of columns present after the label column (e.g., for weights). Level-zero models do not use these columns as standard features, but you can pass these columns to the level-one model using the `extraCallArguments` argument logic. The default value is `0`.

`preservedColumnsForLevelOne` — A list of integers representing column indices (1-based) from the input data. The stacking model passes these specified columns to the level-one model. This option is useful if the level-one model needs to access raw features to improve the base model predictions.

If you do not specify this option, the default value is an empty list (i.e., no original features are preserved).

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

## Execute the Model

This example demonstrates how a stacking model can embed level-zero and level-one child models. The JSON `OPTIONS` string includes two level-zero models (random forest and gradient boosted trees) and produces the final prediction using the level-one model (logistic regression). Each models specifies its own options for how to run.

In the example, the random forest model ( `rf_base` ) uses 200 decision trees. This model explicitly ignores columns 3 and 4, training only on columns 1 and 2. In contrast, the gradient boosted trees model ( `gbt_base` **)** uses 300 decision trees and all available columns.

The level-one model uses logistic regression to combine the outputs of the two base models. The model takes the predictions from `rf_base` and `gbt_base` as its inputs and produces the final classification result.

© 2026 Ocient, Inc Ocient Proprietary and Confidential

When you run the stacking model, the stacking model first executes the base models in parallel (up to the `maxThreads` value). The resulting predictions then go into the logistic regression meta-model to generate the final score.

SQL

```
CREATE MLMODEL my_schema.stacking_classifier
TYPE STACKING
OPTIONS (
    -- Level-0 (Base) Models
    'levelZeroModels' = '[
        {
            "type": "RANDOM FOREST",
            "name": "rf_base",
            "options": {
                "numTrees": 200,
                "maxDepth": 12
            },
            "ignoreColumns": "3,4"
        },
        {
            "type": "GRADIENT BOOSTED TREES",
            "name": "gbt_base",
            "options": {
                "numChildren": 300,
                "learningRate": 0.05
            }
        }
    ]',

    -- Level-1 (Meta) Model
    'levelOneModel' = '{
        "type": "LOGISTIC REGRESSION",
        "name": "stacking_meta",
        "options": {
            "maxIterations": 200,
            "regularization": 0.1
        }
    }',

    -- Top-level STACKING options
    'maxThreads' = '16',
    'hasLabelColumn' = 'true'
)
AS
SELECT
    feature1,
    feature2,
```

```
    feature3,
    feature4,
    label
FROM my_schema.training_data;
```

After training completes, execute the stacking model.

SQL

```
SELECT
    my_schema.stacking_classifier(feature1, feature2, feature3, feature4)
FROM my_schema.scoring_data;
```

# Other Models

Reference for additional OcientML model types beyond classification, clustering, and regression, including association rules, time series, and neural networks.

OcientML™ supports other machine learning models for advanced analysis that include association rules, multi-layer perceptron (MLP), and undersampling.

To create the model, use the `CREATE MLMODEL` syntax. For details, see **CREATE MLMODEL**.

> Model option names are case-sensitive.

## Association Rules

Model Type: `ASSOCIATION RULES`

The association rules model trains itself over rows of arrays to suggest other associated values. The model returns values commonly associated with a set that are absent in the provided value set. In practical use, this model is often used to help in retail transactions by suggesting related items or services for purchase based on similar past transactions.

### Model Options

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training, where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training, where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Execute the Model

Create an association rules model. When you create the model, there should be a single input column of type `array`, with any inner type.

```sql
CREATE MLMODEL my_model
TYPE ASSOCIATION RULES ON (
  SELECT
    array_agg(product)
  FROM public.my_table
  GROUP BY customer_id
);
```

Also, after you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model, you must provide an array with the same inner type as the input column. The array represents the current state of the transaction.

You must also provide a second argument, a positive integer representing the association ranking of the item to return. The value of `1` indicates that the model should add the most-associated item to the transaction.

The third and fourth arguments are optional constant Boolean values.

If the third argument is set to `true`, the model adds the most-associated item to the transaction, based on other transactions that include the same items as the current transaction. Otherwise, only some of the items must be the same. The third argument defaults to `true`.

If the fourth argument is set to `true`, the model counts duplicate items in a transaction only once. Otherwise, the model counts duplicate items multiple times. To specify the fourth argument, you must specify the third argument. The default value for the fourth argument is `true`, which means duplicate items are counted once.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT my_model(array['sausage', 'mushrooms'], 1);
SELECT my_model(array['sausage', 'mushrooms'], 1, true, true);
```

The output from the model is a tuple `( v, p, c )`. The definitions of these tuple values are:

`v` — The associated item determined by the model based on your input arguments.

`p` — The proportion of arrays in the training data that contain the items of the input array and the associated item `v`, as compared to arrays in the training data that have the input items but not necessarily the associated item `v`.

`c` — The count of occurrences of the associated item `v` in the training data arrays based on your input arguments.

After you execute a model, you can find the details about the execution results in the `sys.association_rules_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in the **System Catalog**.

## Multi-Layer Perceptron (MLP)

Model Type: `MLP`

> The legacy model type name `FEEDFORWARD NETWORK` is also acceptable for backward compatibility.

The MLP model is a fully connected feedforward neural network in which data flows from the inputs through hidden layers to the outputs. The number of columns in the input result set determines the number of inputs. Each input must be numeric. The last column in the input result set is the target variable. For models with one output, the column is also numeric. For models with multiple outputs, the result must be a 1xN matrix (a row vector).

Common uses of multiple output models are:

- Multi-class classification — Multiple outputs are one-hot encoded values that represent the class of the record. The model uses results with argmax to select the highest probability class.
- Probability modeling — Multiple output values represent probabilities between 0 and 1 that sum to 1.
- Multiple numeric prediction — Multiple output values represent different numeric values to predict against.

## Model Options

### Required

`hiddenLayers` — You must set this option to a positive integer that specifies how many hidden layers to use.

`hiddenLayerSize` — You must set this option to a positive integer that specifies the number of nodes in each hidden layer.

`outputs` — You must set this option to a positive integer that specifies the number of outputs.

`lossFunction` — This option specifies the loss function that all hidden layer nodes and all output layer nodes use. This function can be one of several predefined loss functions or a user-defined loss function.

The predefined loss functions are `squared_error` (regression), `vector_squared_error` (vector-valued regression), `log_loss` (binary classification with target values of 0 and 1), `logits_loss` (binary classification with target values of 0 and 1), `hinge_loss` (binary classification with target values of -1 and 1), and `cross_entropy_loss` (multi-class classification). If the value for this required parameter is none of these strings, the model assumes a user-defined loss function. The user-defined loss function specifies the per-sample loss. Then, the actual loss function is the sum of this function applied to all samples. The model should use the variable `y` to refer to the dependent variable in the training data, and the model should use the variable `f` to refer to the computed estimate for a specified sample.

### Optional

© 2026 Ocient, Inc Ocient Proprietary and Confidential

`activationFunction` — If you set this option, the values are `linear`, `relu` (rectified linear unit), `leakyrelu` (leaky rectified linear unit), `tanh` (hyperbolic tangent function), or `sigmoid` (fast sigmoid approximation). This option defaults to `relu`. This option affects all layers except the output layer.

`outputActivationFunction` — If you set this option, the values are `linear`, `relu` (rectified linear unit), `leakyrelu` (leaky rectified linear unit), `tanh` (hyperbolic tangent function), or `sigmoid` (fast sigmoid approximation). Different activation functions have different output ranges. The chosen activation function should match the dependent variable of your data. For example, if the dependent variable can be anything, then choose the `linear` value. If the dependent variable is always positive, then choose the `relu` value. If your outputs range from -1 to 1 or you perform hinge loss classification, `tanh` is a good option because the hyperbolic tangent function has the same range. However, if your outputs range from 0 to 1 or you perform log loss classification, `sigmoid` is a better choice for the same reason. This option defaults to `linear`. The option only sets the activation function for the output layer.

`metrics` — If you set this option to `true`, the model calculates the average value of the loss function.

`useSoftMax` — If you set this option to true, the model applies a softmax function to the output of the output layer before computing the loss function. This option defaults to `true` if the `lossFunction` is set to `cross_entropy_loss` and `false` otherwise.

`minInitParamValue` — If you set this option, the value must be a floating-point number that sets the minimum for initial parameter values in the optimization algorithm. This option defaults to -1.

`maxInitParamValue` — If you set this option, the value must be a floating-point number that sets the maximum for initial parameter values in the optimization algorithm. This option defaults to 1.

`normalize` — If you set this option to `true`, this option applies z-score normalization to inputs by default, storing means and standard deviation, and automatically applying them at inference. This option defaults to `true`.

`finiteDifferenceH` — A `DOUBLE` value representing the step size (h) for approximating gradients using the finite difference method. The model uses this value

only if analytical gradients are not active.

This value should generally be a small positive value, typically from 0.0001 (1e-4) to 0.0000001 (1e-7).

If you do not specify this value, the default is 0.00001 (1e-5).

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training, where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`skipDropTable` — If you set this option to `false` , the database deletes any intermediate tables created during model training. If you set this option to `true` , the database prevents the deletion of any intermediate tables created during model training. The default value is `false` .

## Execute the Model

Create a neural network to perform multi-class classification for three possible classes. `y1` , `y2` , and `y3` are one-hot encoded outputs. If the values are 1 and the rest are 0, the value 1 denotes the class that the training data belongs to from the three classes.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE MLMODEL my_model
TYPE MLP
ON (
  SELECT
    x1,
    x2,
    {{y1,y2,y3}}
  FROM public.my_table
)
options(
  'hiddenLayers' -> '1',
  'hiddenLayerSize' -> '8',
  'outputs' -> '3',
  'lossFunction' -> 'cross_entropy_loss',
  'activationFunction' -> 'relu',
  'useSoftmax' -> 'true'
);
```

Also, after you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

When you execute the model later, pass `N - 1` input variables, and the model returns the estimate of the target variable. In the case of multiple outputs, the result is a 1xN matrix (a row vector). If the model uses multiple outputs to perform multi-class classification, use `argmax` to get the integer that represents the class.

SQL

```
SELECT argmax(my_model(x1, x2)) FROM my_table;
```

After you execute a model, you can find the details about the execution results in the `sys.mlp_models` system catalog table.

For details, see the description of the associated system catalog tables in the Machine Learning section in the **System Catalog**.

# Undersampling

Model Type: `UNDERSAMPLING`

The undersampling model is a preprocessing primitive that addresses class imbalance — for example, when a fraud detection data set has far more legitimate transactions than fraudulent ones. The model produces a sampled output table with a more balanced class distribution. Unlike other model types, you cannot use the undersampling model as a function in a `SELECT` statement. Instead, the model creates an output table in the `temp` system schema that contains a subset of the input data, with non-target classes downsampled relative to the target class. You can query this output table directly, for example, as input to train a downstream classifier. To find the output table name, query the `sys.undersampling_models` system catalog table.

> ⚠ Sampling is non-deterministic. Actual row counts in the output table might vary by approximately the square root of the expected count.

## Model Options

> ⓘ The model-specific options for Undersampling ( `classColumn` , `samplingRatio` , `strategy` , `stratumColumn` , and `targetClass` ) are in beta and subject to change in a future release.

### Required

`classColumn` — This option specifies the name of the column in the training `SELECT` statement whose values define the class labels. The column can be any comparable type (for example, `VARCHAR` , `INT` ).

### Optional

`strategy` — This option specifies the sampling strategy. Accepted values are `'random'` (per-row Bernoulli sampling) and `'stratified'` (quota-based sampling that preserves per-stratum proportions). The default value is `'random'` .

`stratumColumn` — This option specifies the name of the column that defines strata for stratified sampling. The option is required when you set the `strategy` option to `'stratified'` and is not valid otherwise.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`samplingRatio` — This option specifies the ratio of non-target class rows to target class rows in the output. The value must be a positive finite double. For example, a value of `1.0` produces approximately equal counts of target and non-target rows. The default value is `1.0`.

`targetClass` — This option specifies which class label to treat as the target (minority) class. If you set this option to `'auto'`, the model automatically selects the class with the fewest rows. You can also set this option to an explicit label value that matches a value in the `classColumn`. The default value is `'auto'`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training, where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training, where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

## Execute the Model

Create an undersampling model to balance a binary classification data set. The `label` column contains the class labels. With the default `samplingRatio` of `1.0` and `targetClass` of `'auto'`, the model selects the minority class and down-samples the majority class to approximately the same count.

© 2026 Ocient, Inc

SQL

```
CREATE MLMODEL my_undersampler
TYPE UNDERSAMPLING
ON (
  SELECT *
  FROM public.my_table
)
options(
  'classColumn' -> 'label'
);
```

After you create the model, the sampled output table is available in the `temp` schema. You can query it by looking up the table name in the `sys.undersampling_models` system catalog table.

SQL

```
SELECT * FROM temp.us_my_undersampler_<timestamp>_output;
```

The database automatically drops the output table when you execute the `DROP MLMODEL` SQL statement on the undersampling model.

Also, after you create the model, you can see its details by querying the `sys.machine_learning_models` and `sys.machine_learning_model_options` system catalog tables.

For details, see the description of the associated system catalog tables in the Machine Learning section of the **System Catalog**.

# Machine Learning Model Options

Reference for OcientML model options, including required and optional parameters for association rules, bagging, boosting, decision trees, k-means, and more.

This list of options contains model options for all models in the Ocient® System.

## Association Rules

### Model Options

#### Optional

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`temporalOrdering` — If you set this option to `true` , the model treats antecedent items as those appearing earlier in time and consequent items as those appearing later, within the same transaction. Also, you must specify the `transactionColumn` and `timeColumn` options. The training input is a per-item table with shape `(transaction_id, time, item)` rather than the default unordered `ARRAY` per row. The default value is `false` , and the model preserves the unordered behavior unchanged.

`timeColumn` — The name of the column in the training `SELECT` SQL statement that orders items within a transaction. This option is required when you set the `temporalOrdering` option to `true` . Otherwise, the database throws a syntax error. The model ignores this option when you do not set the `temporalOrdering` option or set it to `false` . The column must be a numeric or temporal type that supports `<` , `>` , and `MAX()` expressions.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`transactionColumn` — The name of the column in the training `SELECT` SQL statement that groups items into one basket or sequence. This option is required when you set the `temporalOrdering` option to `true`. Otherwise, the database throws a syntax error. The model ignores this option when you do not set the `temporalOrdering` option or set it to `false`.

# Backward Feature Elimination

## Model Options

### Required

`evaluationMetric` — This option specifies the criterion that drives the search loop. For classification inner models, supported values are `accuracy`, `f1_macro`, `f1_weighted`, `mcc`, `auc_roc`, and `log_loss`. For regression inner models, supported values are `r_squared`, `rmse`, `mae`, and `mape`.

`innerModelType` — This option specifies the model type for the inner supervised learner that the wrapper model repeatedly trains on candidate column subsets. The value must be a model type that supports classification or regression. Examples include `logistic regression`, `multiple linear regression`, and `decision tree`.

### Optional

`holdoutFraction` — If you set this option, the value must be a positive double in the range (0, 0.5] that represents the fraction of the training data the wrapper model holds out for trial scoring. The model trains trials on the complementary partition and scores on the holdout partition. The default value is `0.2`.

`innerModelOptions` — If you set this option, the value must be a JSON object where the keys are option names that are accepted by the inner model type. The wrapper model forwards these options verbatim to every `CREATE MLMODEL` SQL statement the model executes. The default value is an empty object.

`maxFeatures` — This option specifies the maximum number of features. The Forward Feature Selection model honors this value. Backward Feature Elimination accepts this value but does not use it. The default value is unlimited.

© 2026 Ocient, Inc Ocient Proprietary and Confidential

`maxIterations` — If you set this option, the value must be a positive integer that represents the maximum number of search rounds. The default value is `100`.

`metricDirection` — If you set this option, the value must match the natural direction of the chosen `evaluationMetric` option: `higher_is_better` for `accuracy`, `f1_macro`, `f1_weighted`, `mcc`, `auc_roc`, and `r_squared`; `lower_is_better` for `log_loss`, `rmse`, `mae`, and `mape`. This option acts as a sanity-check assertion; it cannot override the metric's natural direction. The default is the natural direction of the chosen `evaluationMetric` option value.

`metricThreshold` — If you set this option, the value is an absolute score threshold at which the search terminates early. This option is mutually exclusive with the `relativeAcceptable` option.

`minFeatures` — This option specifies the minimum number of features. The Backward Feature Elimination model honors this value as the floor cardinality of the surviving subset. The Forward Feature Selection model accepts this value but does not use it. The default value is `1`.

`parallelism` — If you set this option, the value must be a positive integer that bounds how many candidate trial trainings the wrapper model runs concurrently within a single round. The default value is `5`. The model limits actual concurrency to the range `[1, min(numCandidates, hardware_concurrency())]`.

`relativeAcceptable` — If you set this option, the value is a percentage that represents how far below the full-feature reference score the wrapper model accepts. This option is mutually exclusive with the `metricThreshold` option.

# Bagging

## Model Options

### Required

`baseModels` — This option specifies the children of the bagging model. You must specify this value as a JSON array, where each object in the array has the three fields `type`, `count`, and `options`.

`taskType` — This option specifies the type of task, which must be either `CLASSIFICATION` or `REGRESSION` depending on the type of model for training.

## Optional

`ROCNumSamples` — If you set this option, you must specify a positive integer that represents the number of samples for the model to use when calculating the area under the ROC curve. You must also set the `metrics` option to `true`. The default value is the number of child models.

`bootstrap` — If you set this option to `true`, the model uses bootstrap sampling with replacement, meaning each child model trains on a random subset of the data (either the `rowsPerChild` or `fractionSelected` value sets the exact number of rows), and the same row can appear multiple times for each child. If you set this option to `false`, the model does not use replacement, meaning each row can appear at most one time per child. The default value is `false`.

`continuousFeatures` — If you set this option, the value must be a comma-separated list of the feature indexes that are continuous numeric variables. Indexes start with 1. In the default state, the model considers no features as continuous.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`fractionSelected` — If you set this option, the option represents the proportion of rows the model uses to train each child model. The value is a `double` that must be in the interval (0, 1]. You cannot set this option if you also set the `rowsPerChild` option to a positive value. The default behavior is that the model uses all available rows.

`inputsPerChild` — If you set this option, the option represents the number of features used to create each child model. The default value is the total number of features divided by 3 and rounded up.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`maxChildThreads` — If you set this option, the value must be an integer representing the maximum number of threads each child model can use. If a child accepts a `maxThreads` option, the model passes this value to the child.

`maxThreads` — If you set this option, the option represents the maximum number of parallel threads to use while the model trains. This value must be a positive integer. The default value is 16.

`metrics` — If you set this option to `true`, the system calculates certain metrics depending on the value of the `taskType` option. If you set the `taskType` option to `CLASSIFICATION`, the metrics are the percentage of correctly classified rows and the area under the ROC curve. If you set the value to `REGRESSION`, the metrics are the root mean square error and the adjusted R-squared. The default value is `false`.

`requiredFeatures` — If you set this option, the value must be a comma-separated list of integers representing features starting at index 1. The bagging model passes these features down to every child. The default value is an empty list, meaning there is no required feature.

`rowsPerChild` — If you set this option to a positive integer, the number represents the number of rows (from a random sample) to use for each decision tree. If you set this option to 0, each child uses all available rows. The default value is 0. You cannot set this option to a positive value if you also set the `fractionSelected` option.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`weighted` — If you set this option, the system passes the value directly to child models that support it. The behavior depends on the model type of the target child.

## Boosting

## Model Options

### Required

`baseModels` — This option specifies the children of the bagging model. You must specify this as a JSON array, where each object in the array has the three fields `type`, `count`, and `options`.

`learningRate` — A `decimal` value between 0.0 and 1.0 that tunes how much the model learns from each successive child.

`taskType` — This option specifies the type of task, which must be either `CLASSIFICATION` or `REGRESSION` depending on the type of model for training.

### Optional

`ROCNumSamples` — If you set this option, you must specify a positive integer that represents the number of samples for the model to use when calculating the area under the ROC curve. You must also set the `metrics` option to `true`. The default value is `10`.

`continuousFeatures` — If you set this option, the value must be a comma-separated list of the feature indexes that are continuous numeric variables. Indexes start with 1. In the default state, the model considers no features as continuous.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`fractionSelected` — If you set this option, the option represents the proportion of rows the model uses to train each child model. The value is a `double` that must be in the interval (0, 1]. You cannot set this option if you also set the `rowsPerChild` option to a positive value. The default behavior is that the model uses all available rows.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`inputsPerChild` — If you set this option, the value must be an `integer` type that is greater than or equal to 1, which specifies the number of input features each boosting child should use. This value cannot exceed the number of input features available in the data set. When you specify this value, the algorithm deterministically cycles through pre-enumerated feature subsets to ensure each child uses exactly the specified number of features. When you do not specify this value, the model uses all available features for each child.

`lossFunction` — If you set this option, the value represents the loss function used by the model. Accepted values are: `'squared_error'` and `'log_loss'`. When you set this value to `'squared_error'`, the model calculates errors as the squared difference between predicted and actual values. The target column must contain numeric values. This is the default value when the `taskType` option is set to `REGRESSION`. When you set this value to `'log_loss'`, the model calculates errors using logistic loss. This is the default value when the `taskType` option is `CLASSIFICATION`.

`maxThreads` — If you set this option, the option represents the maximum number of parallel threads to use while the model trains. This value must be a positive integer. The default value is 16.

`metrics` — If you set this option to `true`, the system calculates certain metrics depending on the value of the `taskType` option. If the `taskType` option is set to `CLASSIFICATION`, the metrics are the percentage of correctly classified rows and the area under the ROC curve. If the `taskType` option is set to `REGRESSION`, the metrics are the root mean square error and the adjusted R-squared. The default value is `false`.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

## Dbscan

## Model Options

### Required

`epsilon` — The distance threshold for the eps-neighborhood the system uses during computation of the k-nearest neighbors (KNN) graph. You must set this option to a finite positive `double`.

`minPts` — The minimum number of neighbors (including the row itself) required for a row to qualify as a core point. You must set this value to a positive integer.

### Optional

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`insertBatchSize` — If you set this option, the value must be a positive integer that starts at `1`. This value controls how many `(row_id, cluster_id)` pairs the model batches into each `INSERT INTO temp.<...> VALUES (...)` statement when materializing the cores table at the end of training. Smaller batches under-utilize the per-statement INSERT overhead; larger batches stress the SQL parser. The default value is `131072` (= 128 * 1024).

`kNeighbors` — If you set this option, the value must be a positive integer that is at least as large as the `minPts` option value. This value controls the number of nearest neighbors the system uses when materializing the KNN graph at training time. Higher values trade training cost for better border-point recall at the fixed `epsilon` option value. The default value is `max(20, minPts * 4)`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`metric` — If you set this option, the value must be one of `'euclidean'`, `'cosine'`, or `'manhattan'`. This value selects the distance metric for the KNN graph and inference. The default value is `'euclidean'`.

`normalize` — If you set this option to `true`, the database normalizes each feature column to the zero mean and unit standard deviation before computing distances. The default value is `true`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

# Decision Tree

## Model Options

### Optional

`ROCNumSamples` — If you set this option, you must specify a positive integer that represents the number of samples for the model to use when calculating the area under the ROC curve. You must also set the `metrics` option to `true`. The default value is `10`.

`continuousFeatureBatchSize` — If you set this option, the value must be a positive `integer`. This value sets the maximum number of continuous features where the system combines split-aggregate queries into a single `UNION ALL` query during decision tree training. Higher values reduce per-query dispatch and compile overhead, especially for wide-feature datasets, but increase peak SQL Node memory holding the

combined result set. The worst-case combined result set scales with this value multiplied by the `numClasses` and `numSplits` values. The default value is `256`, which matches the `distinctCountLimit` value of the discrete path so that per-chunk peak result-set memory stays comparable to (and in practice well below) what the discrete path already produces in a single `UNION ALL` query across all discrete features without chunking. Lower this value if you observe SQL Node memory pressure on workloads with very high `numClasses` or `numSplits` values; raise it for narrow workloads with low cardinality where dispatch overhead dominates. This option only affects continuous features. The discrete path already uses a single `UNION ALL` across all features per node.

`continuousFeatures` — If you set this option, the value must be a comma-separated list of the feature indexes that are continuous numeric variables. Indexes start with 1. In the default state, the model considers no features as continuous.

`distinctCountLimit` — If you set this option, the value must be a positive `integer` type. This value sets the limit for how many distinct values a non-continuous feature and label can contain. The default value is `256`.

`doPrune` — If you set this option to `true`, the model uses Pessimistic Error Pruning (PEP) to prune the tree after training. The default value is `false`.

`enableResplits` — If you set this option, it must be a `boolean` type that determines if the tree can reuse the same continuous feature multiple times along a single branch (e.g., split on `x1 < 7` and later `x1 < 3`). This action can capture more complex, range-specific relationships. The default value is `true`, meaning that continuous features remain available for additional splits after use, thereby allowing the tree to create more complex decision boundaries. If you set this option to `false`, the model marks continuous features as exhausted after their first use, and the model cannot use them again in subsequent splits in the same tree.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes

of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`featureSubsetStrategy` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the option specifies how many features the decision tree should consider at each split from the still-available features. When this value is higher, the model has a higher accuracy and lower variance, but takes longer to train. You can specify this option either as an integer (e.g., `4`, meaning consider up to four features at each split) or one of these values: `all` (check every feature), `sqrt` (check up to the square root of the number of total features), `log2` (check up to the base-2 logarithm of the number of total features), and `one-third` (check up to one-third of the number of total features). The default value is `all`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`maxCellsToFetch` — If you set this option, the value must be a positive integer. Controls the chunking behavior when fetching feature values during model training. The limit represents the maximum number of data cells (calculated as number of columns × number of rows) that can be fetched in a single operation, not a byte limit. When the expected data size exceeds this threshold, the algorithm switches to database-based processing using SQL queries instead of in-memory processing. This value defaults to 33,554,432 cells (calculated as 32 × 1024 × 1024).

`maxDepth` — If you set this option, the value must be a positive integer. This value sets the maximum allowable depth of the decision tree (the maximum number of features to split on). The default is unspecified, which means there is no maximum depth.

`maxLeafNodes` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be an integer greater than or equal to `2`. This value caps the number of leaf nodes in the decision tree during the standard depth-first build. When the tree reaches this limit, the model stops queuing further splits and converts pending nodes to leaves; this is a soft cap rather than the best-first growth, so the resulting tree might differ from a best-first tree of the same leaf budget. The default value is unspecified, which means there is no limit on the number of leaf nodes.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`maxRows` — If you set this option, the value must be a positive integer. This option limits the number of rows used for model training by creating a snapshot table with only the specified number of rows from the input query. When this option is unspecified, the model trains using all rows from the input query.

`maxThreads` — If you set this option, the value must be a positive integer. This value indicates the maximum number of parallel threads to use while the model trains. The default value is 2.

`metrics` — If you set this option to `true`, the model also calculates the percentage of samples correctly classified by the model and saves this information in a catalog table. This option defaults to `false`.

`minImpurityDecrease` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a non-negative `double`. The tree splits only if the decrease in impurity (the difference between the parent node impurity and the weighted sum of child node impurities) is greater than or equal to this value. The default value is `0.0`, meaning the model accepts all splits that improve impurity.

`minSamplesLeaf` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive integer. This value sets the minimum number of samples required in a leaf node. The model rejects any split that creates a child node with fewer samples than this value, making the node a leaf instead. The default value is `1`, meaning every leaf must have at least one sample.

`minSamplesSplit` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be an integer greater than or equal to `2`. This value sets the minimum number of samples required to split a node. Nodes with fewer samples than this value become leaves. The default value is `2`.

`numSplits` — If you set this option, the value must be an integer greater than 1. This value sets the maximum number of binary branches a continuous feature can consider. The default value is 32.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes

during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`skipLimitCheck` — If you set this option to `true`, the model skips cardinality checks that throw errors when columns have too many values. The limit that this option checks is the same one specified by the `distinctCountLimit` option. The default value is `false`.

`splitMetric` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the option controls which function the model uses to evaluate the quality of a split during tree construction. Supported options are: `gini_impurity` (measures impurity based on class distributions), `entropy` (measures impurity using information entropy, i.e., `-SUM(p_k * ln(p_k))`), and `hellinger` (uses the Hellinger distance, which requires exactly two output classes). The default value is `gini_impurity`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`suppressJIT` — If you set this option to `true`, the model suppresses just-in-time code generation.

`weighted` — If you set this option, the model considers weights for labels. If you set this option value to `true`, you must specify an additional column as a `double` in the training data for label weights. Rows with the same labels must have the same weights. If you set this value to `auto`, the model calculates weights automatically by weighting each label according to the ratio of the count of the most frequent label to the count of the specified label. As a result, the most frequent label has the weight `1.0` and the other label weights are higher. The default value is `false`, which means all labels have equal weight.

## Forward Feature Selection

## Model Options

### Required

`evaluationMetric` — This option specifies the criterion that drives the search loop. For classification inner models, supported values are `accuracy`, `f1_macro`, `f1_weighted`, `mcc`, `auc_roc`, and `log_loss`. For regression inner models, supported values are `r_squared`, `rmse`, `mae`, and `mape`.

`innerModelType` — This option specifies the model type for the inner supervised learner that the wrapper model repeatedly trains on candidate column subsets. The value must be a model type that supports classification or regression. Examples include `logistic regression`, `multiple linear regression`, and `decision tree`.

### Optional

`holdoutFraction` — If you set this option, the value must be a positive double in the range (0, 0.5] that represents the fraction of the training data the wrapper model holds out for trial scoring. The model trains trials on the complementary partition and scores on the holdout partition. The default value is `0.2`.

`innerModelOptions` — If you set this option, the value must be a JSON object where the keys are option names that are accepted by the inner model type. The wrapper model forwards these options verbatim to every `CREATE MLMODEL` SQL statement the model executes. The default value is an empty object.

`maxFeatures` — This option specifies the maximum number of features. The Forward Feature Selection model honors this value. Backward Feature Elimination accepts this value but does not use it. The default value is unlimited.

`maxIterations` — If you set this option, the value must be a positive integer that represents the maximum number of search rounds. The default value is `100`.

`metricDirection` — If you set this option, the value must match the natural direction of the chosen `evaluationMetric` option: `higher_is_better` for `accuracy`, `f1_macro`, `f1_weighted`, `mcc`, `auc_roc`, and `r_squared`; `lower_is_better` for `log_loss`, `rmse`, `mae`, and `mape`. This option acts as a sanity-check assertion; it cannot override the metric's natural direction. The default is the natural direction of the chosen `evaluationMetric` option value.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`metricThreshold` — If you set this option, the value is an absolute score threshold at which the search terminates early. This option is mutually exclusive with the `relativeAcceptable` option.

`minFeatures` — This option specifies the minimum number of features. The Backward Feature Elimination model honors this value as the floor cardinality of the surviving subset. The Forward Feature Selection model accepts this value but does not use it. The default value is `1`.

`parallelism` — If you set this option, the value must be a positive integer that bounds how many candidate trial trainings the wrapper model runs concurrently within a single round. The default value is `5`. The model limits actual concurrency to the range `[1, min(numCandidates, hardware_concurrency())]`.

`relativeAcceptable` — If you set this option, the value is a percentage that represents how far below the full-feature reference score the wrapper model accepts. This option is mutually exclusive with the `metricThreshold` option.

# Gaussian Discriminant Analysis

## Model Options

### Optional

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`metrics` — If you set this option to `true`, the model calculates classification quality metrics (accuracy, MCC, AUC ROC, and per-class precision, recall, and F1) on the validation data (or the training data if you do not specify the `VALIDATE ON` clause) and stores them in the `sys.gaussian_discriminant_analysis_models` system catalog table. The default value is `false`.

`normalize` — If you set this option to `true`, the model automatically computes the mean and standard deviation of each feature. Then, the model normalizes the training data using the mean and standard deviation and stores these values so that the inference normalizes inputs identically. The default value is `true`.

`priors` — This option specifies how the model computes class priors P(c). If you set this option to `'empirical'`, the model uses observed class frequencies in the training data. If you set this option to `'uniform'`, the model assigns each of the K classes a prior of 1/K, which is the correct choice when the class proportions in the training data do not reflect the population. The default value is `'empirical'`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`regParam` — If you set this option, the value must be a non-negative `double` representing a ridge term added to each per-class covariance diagonal before inversion (Sigma_c <- Sigma_c + regParam * I). Use a strictly positive value when classes have low row counts or when strongly correlated features render the unregularized covariance rank-deficient. The default value is `0.0`.

`suppressArrayLengthCheck` — If you set this option, you must set the `featureArray` option to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

# Gaussian Mixture Model

## Model Options

### Required

`numDistributions` — This option must be a positive `integer` type that specifies the number of clusters of Gaussian distributions for the model to make.

## Optional

`covarianceType` — (BETA. This option is part of an in-development feature and is subject to change.) Specifies the type of covariance matrix to use. The values are: `full` (each component has its own full covariance matrix), `diag` (each component has its own diagonal covariance matrix), `spherical` (each component has a single variance shared across all features), or `tied` (all components share the same full covariance matrix). The default value is `full`.

`epsilon` — If you specify this option, the value must be a valid positive floating point number. When the maximum distance that the entire best model moves in its n-dimensional space is less than this value, the algorithm terminates. The default value is `0.00000001` ( `1e-8` ).

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`maxIterations` — If you set this option, the option represents the maximum number of optimization iterations to train the model. For higher values of this option, the model is likelier to converge to the expected `epsilon`, but it might take longer to train. The default value is `100`.

`normalize` — If you set this option to `true`, the model automatically computes the mean and standard deviation of each feature and uses them to normalize the data during training. Defaults to `true`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`numInitializations` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value specifies the number of times the model runs the full training procedure with different random k-means initializations while keeping the result with the best log-likelihood. The default value is `1`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

# Gradient Boosted Trees

## Model Options

### Required

`learningRate` — A `decimal` value between 0.0 and 1.0 that tunes how much the model learns from each successive child.

`numChildren` — An `integer` value representing the total number of trees to build sequentially. Each tree learns to correct the errors of the previous trees.

### Optional

`ROCNumSamples` — If you set this option, you must specify a positive integer that represents the number of samples for the model to use when calculating the area under the ROC curve. You must also set the `metrics` option to `true`. The default value is `10`.

`continuousFeatures` — If you set this option, the value must be a comma-separated list of the feature indexes that are continuous numeric variables. Indexes start with 1. In the default state, the model considers no features as continuous.

`earlyStoppingRounds` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a non-negative `integer`.

Training stops if the loss does not improve for this number of consecutive trees. The model computes the loss on the training data (the same data used to fit each tree). The value `0` disables early stopping. The default value is `0`.

`earlyStoppingTolerance` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a non-negative `double`. This value sets the minimum relative improvement in loss required to count as an improvement for early stopping. A new loss `L` counts as an improvement only if `L < bestLoss - tolerance * |bestLoss|`. Use this option only when the `earlyStoppingRounds` value is greater than `0`. The default value is `0.0001` ( `1e-4` ).

`enableResplits` — If you set this option, the value must be a `boolean` type that determines if the tree can reuse the same continuous feature multiple times along a single branch (e.g., split on `x1 < 7` and later `x1 < 3`). This action can capture more complex, range-specific relationships. The default value is `true`, meaning that continuous features remain available for additional splits after use, thereby allowing the tree to create more complex decision boundaries. If you set this option to `false`, the model marks continuous features as exhausted after their first use, and the model cannot use them again in subsequent splits in the same tree.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`featureSubsetStrategy` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the model passes this option directly to the child regression trees. The option specifies how many features each child tree should consider at each split from the still-available features. When this value is higher, the model has higher accuracy and lower variance, but takes longer to train. You can specify this option either as an integer (e.g., `4`, meaning consider up to 4 features at each split) or one of these values: `all` (checks every feature), `sqrt` (checks up to the square root of the number of total features), `log2` (checks up to the base-2

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

logarithm of the number of total features), and `one-third` (checks up to one-third of the number of total features). The default value is `all`.

`fractionSelected` — If you set this option, the option represents the proportion of rows the model uses to train each child model. The value is a `double` that must be in the interval (0, 1]. You cannot set this option if you also set the `rowsPerChild` option to a positive value. The default behavior is that the model uses all available rows.

`inputsPerChild` — If you set this option, the value must be an `integer` type greater than or equal to 1 that specifies the number of input features each boosting tree should use. This value cannot exceed the number of input features available in the data set. When you specify this value, the algorithm deterministically cycles through pre-enumerated feature subsets to ensure each tree uses exactly the specified number of features. The default behavior is that the model uses all available features for each tree.

`lossFunction` — If you set this option, the option represents the loss function used and determines the type of task the model does. Accepted values are: `'squared_error'` and `'log_loss'`. When you set this value to `'squared_error'`, the model calculates errors as the squared difference between predicted and actual values. The target column must contain numeric values. This is the default value for regression tasks. When you set this value to `'log_loss'`, the model calculates errors using logistic loss. This is the default value for classification tasks.

`maxCellsToFetch` — If you set this value, the value must be an `integer` type that determines the memory threshold to switch from training with system memory to training with SQL queries in the database. In-memory training is generally faster, but is limited by the available SQL Node memory. If the size of a training data subset exceeds this value, then the system performs training operations using SQL queries. The default value is `33,554,432` (calculated as `32 * 1024 * 1024`).

`maxDepth` — If you set this value, the value must be a positive `integer` type that represents the maximum allowable depth of the child trees. The default value is `3`.

`maxLeafNodes` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be an integer greater than or equal to `2`. The model passes this option directly to the child regression trees. This value caps the number of leaf nodes in each child tree during its depth-first build (it is a soft cap

rather than best-first growth). The default value is unspecified, which means there is no limit on the number of leaf nodes.

`maxThreads` — If you set this value, the value must be a positive `integer` type that sets the maximum number of parallel threads to use for training each child decision tree. Parallel threads do not affect the sequential method of training each tree. The default value is `16`.

`metrics` — If you set this value to `true`, the system calculates and stores final model metrics ( `R²/RMSE` for regression or `Accuracy/LogLoss` for classification) on the training data. The default value is `false`.

`minImpurityDecrease` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a non-negative `double`. The child regression tree splits only if the decrease in impurity is greater than or equal to this value. The model passes this option directly to the child regression trees. The default value is `0.0`.

`minSamplesLeaf` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive integer. This value sets the minimum number of samples required in a leaf node for each child regression tree. The model passes this option directly to the child regression trees. The default value is `1`.

`minSamplesSplit` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be an integer greater than or equal to `2`. This value sets the minimum number of samples required to split a node for each child regression tree. The model passes this option directly to the child regression trees. The default value is `2`.

`numSplits` — If you set this option, the value must be an `integer` greater than 1. This value sets the maximum number of binary branches a continuous feature can consider. The default value is `32`.

`regAlpha` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a non-negative `double`. This value sets the L1 regularization strength applied as a post-hoc soft-thresholding of the leaf prediction `t` of each child tree: the model replaces `t` with `sign(t) * max(0, |t| - regAlpha)`. This formula is a leaf-output transform that the model applies after it builds

the child regression tree. The formula is not the L1 term in the second-order objective used by XGBoost, so values do not directly transfer between the two systems. The default value is `0.0` (no L1 regularization).

`regLambda` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a non-negative `double`. This value sets the L2 regularization strength applied as a post-hoc shrinkage of the leaf prediction of each child tree: the model multiplies the leaf output by `1 / (1 + regLambda)`. This formula is a leaf-output transform that the model applies after it builds the child regression tree. The formula is not the L2 term in the closed-form leaf-weight objective used by XGBoost, so values do not directly transfer between the two systems. The default value is `0.0` (no L2 regularization).

`resplitDepth` — If you set this option, the value must be an `integer` type that sets the maximum depth at which tree nodes can be re-split during optimization. This option controls how deep the algorithm searches for better split points. The default value is `6`.

`resplitThreshold` — If you set this option, the value must be a `decimal` type that sets the minimum improvement threshold required to trigger a re-split operation. Lower values allow more aggressive re-splitting but can increase training time. Higher values require larger improvements to trigger re-splits. The default value is `0.1`.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`taskType` — If you set this option, the value determines the task the model performs. Accepted values are `'REGRESSION'` (regression) and `'CLASSIFICATION'` (classification). When you set this option to `'REGRESSION'`, the model sets the default loss function to `'squared_error'`. When you set this option to `'CLASSIFICATION'`, the model sets the default loss function to `'log_loss'`. You can also set the `lossFunction` option explicitly, but it must be compatible with the specified task type. If you set neither the

`taskType` nor `lossFunction` options, the model defaults to regression with the `squared_error` loss function.

# Kmeans

## Model Options

### Required

`k` — This option must be a positive `integer` type that specifies how many clusters to make.

### Optional

`epsilon` — (BETA. This option is part of an in-development feature and is subject to change.) If you specify this option, the value must be a valid positive floating point value. When the maximum distance that a centroid moves from one iteration of the algorithm to the next is less than this value, the algorithm terminates. The default value is `0.0001` ( `1e-4` ).

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`lloydRounds` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the option represents the maximum number of iterations of the Lloyd algorithm to train the model after guessing the centroids. For higher values of this option, the model is more likely to be accurate but takes longer to train. The value `0` indicates an unlimited number of iterations, in which case the algorithm runs only until convergence (see the `epsilon` option). The default value is `20`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`normalize` — If you set this option to `true`, the model normalizes the data before the start of training. The default value is `true`.

`numInitializations` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value specifies the number of times the model runs the full k-means algorithm with different random initializations and keeps the result with the lowest total within-cluster sum of squares (inertia). Higher values increase the chance of finding the globally optimal clustering, but increase training time proportionally. The default value is `1`.

`oversampling` — If you set this option, the option represents the number of candidate guesses for the model to choose in the parallel-round phase of k-means||. For higher values of this option, the model is more likely to be accurate but takes longer to train. The default value is `k`.

`parallelRounds` — If you set this option, the option represents the minimum number of parallel rounds for which the k-means|| algorithm runs. For higher values of this option, the model is more likely to be accurate but takes longer to train. The default value is `8`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

# K Nearest Neighbors

## Model Options

## Required

`k` — This option must be a positive `integer` type that specifies how many closest points to use for classifying a new point.

## Optional

`distance` — If you set this option, the value must be a function in SQL syntax for calculating the distance between a point used for classification and points in the training data set. This function should use the variables x1, x2, ... for the 1st, 2nd, ... features in the training data set, and p1, p2, ... for the features in the point for classification. The default value is the Euclidean distance function.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`normalize` — If you set this option to `true`, the model automatically computes the mean and standard deviation of each feature and uses them to normalize the data during training. The default value is `true`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`weight` — If you specify this option, the value must be a function in SQL syntax for calculating the weight of a neighbor. The function should use the variable d for distance. By default, the distance is set to `1.0 / (d + 0.1)`, thus avoiding division by zero on exact inputs and still allowing neighbors to have some influence.

# Linear Combination Regression

## Model Options

### Required

`functionN` — You must specify the first function using a key named `'function1'`. Subsequent functions must use keys with names that use subsequent values of N. You must specify functions in SQL syntax and should use the variables `x1, x2, ..., xn` to refer to the 1st, 2nd, and nth independent variables, respectively. For example, `'function1' -> 'sin(x1 * x2 + x3)', 'function2' -> 'cos(x1 * x3)'`.

### Optional

`convergenceTolerance` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `double` representing the relative convergence threshold for the Fast Iterative Shrinkage-Thresholding Algorithm (FISTA) optimizer. The optimizer stops when the relative change in coefficients between iterations falls below this value. This option only applies when you set the `lassoCoefficient` option to a positive value. The default value is `0.000001` ( `1e-6` ).

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`fitIntercept` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option to `false`, the model does not fit a y-intercept, forcing

the regression through the origin. This option is equivalent to setting `yIntercept` to `0`, and you cannot combine them. The default value is `true`.

`gamma` — If you set this option, the value must be a matrix. This value represents a Tikhonov gamma matrix used for regularization. For details, see **Tikhonov regularization**.

`huberConvergenceTolerance` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `double` type that represents the convergence tolerance for Huber iteratively reweighted least squares (IRLS) iterations. The algorithm stops when the maximum coefficient change between iterations falls below this value; if the algorithm reaches `huberMaxIterations` first, training succeeds with a warning logged but no error returned. This option only applies when you set the `lossFunction` option to `'huber'`. The default value is `1e-6`.

`huberDelta` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `double` type that represents the Huber loss threshold expressed as a multiple of the residual scale (σ). Residuals smaller than `delta * σ` use squared loss; residuals larger use linear loss. The model estimates σ from the initial OLS fit and refreshes it each IRLS iteration via the weighted residual standard deviation, so a delta of `1.35` matches the convention used by scikit-learn's `HuberRegressor.epsilon` and Spark's `HuberAggregator`. This option only applies when you set the `lossFunction` option to `'huber'`. The default value is `1.35`.

`huberMaxIterations` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `integer` type that represents the maximum number of Huber IRLS iterations. If the algorithm has not converged within this many iterations, training succeeds with a warning logged but no error returned. This option only applies when you set the `lossFunction` option to `'huber'`. The default value is `20`.

`lassoCoefficient` — (BETA. This option is part of an in-development feature and is subject to change.) If you specify this option, the value must be a nonnegative `double`. This option adds L1 (lasso) regularization, which encourages sparse coefficients by driving some toward exactly zero. When you set this option to a positive value, the model uses the FISTA optimizer instead of the closed-form normal equation. When

`normalize=true` (the default), the penalty is applied in standardized space and the persisted coefficients are un-scaled to the original units, matching scikit-learn's `Lasso(normalize=True)` convention. You can combine this option with the `ridgeCoefficient` option for elastic net regularization. You cannot combine this option with the `gamma` option. The default value is `0.0` (no L1 regularization).

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`lossFunction` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be either `'squared_error'` or `'huber'`. When you set this value to `'huber'`, the model uses Huber loss with iteratively reweighted least squares (IRLS), which is robust to outliers. Huber loss cannot be combined with the `lassoCoefficient`, `gamma`, or `weighted` options, and forces `normalize` to `false` because IRLS requires raw-scale residuals. Huber loss IS compatible with the `ridgeCoefficient` and `fitIntercept` options. The default value is `'squared_error'`.

`maxIterations` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `integer` type that represents the maximum number of FISTA iterations. This option only applies when you set the `lassoCoefficient` option to a positive value. The default value is `1000`.

`metrics` — If you set this option to `true`, the model collects quality metrics such as the coefficient of determination (R-squared), the adjusted coefficient of determination, and the root mean squared error (RMSE). The default value is `false`.

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. The default value is `true`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`ridgeCoefficient` — (BETA. This option is part of an in-development feature and is subject to change.) If you specify this option, the value must be a nonnegative `double`. This option adds L2 (ridge) regularization to the normal equation by adding this value times the identity matrix to the X-transpose-X (Gram) matrix before inversion. Larger values shrink the coefficients more toward zero. When `normalize=true` (the default), the penalty is applied in standardized space and the persisted coefficients are un-scaled to the original units, matching scikit-learn's `Ridge(normalize=True)` convention. The default value is `0.0` (no regularization). You can combine this option with the `gamma` option or with the `lassoCoefficient` option for elastic net regularization.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`threshold` — This option enables soft thresholding. If you specify this option, the option must be a positive numeric value. After the model calculates the coefficients, if any coefficients are greater than the threshold value, the model subtracts the threshold value from the coefficients. If any coefficients are less than the negation of the threshold value, the model adds the threshold value to the coefficients. For any coefficients between the negative and positive threshold values, the model sets the coefficients to zero.

`weighted` — If you set this option to `true`, the model performs weighted least squares regression, where each sample has an associated weight or importance. When weighted, there is an extra numeric column after the dependent variable that represents the weight of the sample. The default value is `false`.

`yIntercept` — If you set this option, then the option must be a numeric value. The system forces the specific y-intercept (i.e., the model value when `x` is zero).

# Linear Discriminant Analysis

## Model Options

### Optional

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input

column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`normalize` — If you set this option to `true`, the model automatically computes the mean and standard deviation of each feature and uses them to normalize the data during training. The default value is `true`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

# Logistic Regression

## Model Options

### Optional

`ROCNumSamples` — If you set this option, you must specify a positive integer that represents the number of samples for the model to use when calculating the area under the ROC curve. You must also set the `metrics` option to `true`. The default value is `10`.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input

column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`metrics` — If you set this option to `true`, the model calculates the percentage of samples that are correctly classified by the model and saves this information in the `sys.logistic_regression_models` system catalog table. The default value is `false`.

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. The default value is `true`.

`numEpochs` — If you set this option, the value must be a positive `integer` type representing the maximum number of IRLS iterations during training. The default value is `20`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`ridgeCoefficient` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a non-negative `double` type representing the L2 regularization strength. The model adds this value times an identity matrix to the Hessian diagonal during IRLS optimization, shrinking coefficients toward zero and reducing overfitting. The bias (intercept) term is not regularized. The default value is `0.0` (no regularization).

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the

database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`weighted` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option to `true`, the model performs weighted logistic regression, where each sample has a weight or importance associated with it. In this case, the table includes an additional numeric column after the dependent variable that contains the sample weight. If you set this option to `auto`, the model automatically computes balanced class weights using the formula `weight_k = max_count / count_k`, where `max_count` is the count of the most-frequent class. The most-frequent class receives weight `1.0` and minority classes receive proportionally larger weights; relative weighting between classes is identical to `class_weight='balanced'` from scikit-learn (only the absolute scale differs). The model applies the weight as a multiplier on the per-sample log-loss term during IRLS. The default value is `false`.

# Mlp

## Model Options

### Required

`hiddenLayerSize` — You must set this option to a positive `integer` type that specifies the number of nodes in each hidden layer.

`hiddenLayers` — You must set this option to a positive `integer` type that specifies how many hidden layers to use.

`lossFunction` — This option specifies the loss function that all hidden layer nodes and all output layer nodes use. This function can be one of several predefined loss functions or a user-defined loss function. The predefined loss functions are `squared_error` (regression), `vector_squared_error` (vector-valued regression), `log_loss` (binary classification with target values of 0 and 1), `logits_loss` (binary classification with target values of 0 and 1), `hinge_loss` (binary classification with target values of -1 and 1), and `cross_entropy_loss` (multi-class classification). If the value for this required

option is none of these strings, the model assumes a user-defined loss function. The user-defined loss function specifies the per-sample loss. Then, the actual loss function is the sum of this function applied to all samples. The model should use the variable `y` to refer to the dependent variable in the training data, and the model should use the variable `f` to refer to the computed estimate for the specified sample.

`outputs` — You must set this option to a positive integer that specifies the number of outputs.

## Optional

`activationFunction` — If you set this option, the values are `linear`, `relu` (rectified linear unit), `leakyrelu` (leaky rectified linear unit), `tanh` (hyperbolic tangent function), or `sigmoid` (fast sigmoid approximation). The default value is `relu`. This option affects all layers except the output layer.

`adamBeta1` — If you set this option, the option represents the value of $\beta_1$ in the Adam optimization algorithm. For higher values of this option, training is less noisy but takes longer to converge. The default value is `0.9`.

`adamBeta2` — If you set this option, the option represents the value of $\beta_2$ in the Adam optimization algorithm. For higher values of this option, training is less noisy but takes longer to converge. The default value is `0.99`.

`adamEpsilon` — If you set this option, the option represents the value of $\varepsilon$ in the Adam optimization algorithm. For higher values of this option, training is more numerically stable but takes longer to converge. The default value is `1e-7`.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`finiteDifferenceH` — If you set this option, the value must be a `double` representing the step size ( `h` ) for approximating gradients using the finite difference method. The

model uses this value only if analytical gradients are not active. This value should generally be a small positive value, typically from `0.0001` ( `1e-4` ) to `0.0000001` ( `1e-7` ). The default value is `0.00001` ( `1e-5` ).

`gradientClipThreshold` — If you set this option, the value must be a `double` that represents the gradient norm threshold for clipping. When the overall gradient norm exceeds this threshold, the system scales all gradient components uniformly to preserve direction. This operation prevents issues with exploding gradients in unstable loss landscapes. Set this value to 0 or a negative value to disable gradient clipping. The default value is `1000000` ( `1e6` ).

`learningRate` — If you set this option, the value must be a `double` type representing the base learning rate for the Adam (Adaptive Moment Estimation) machine learning optimizer. Adam adapts this rate individually for each parameter during training. A common starting point for Adam is `0.001` ( `1e-3` ). Valid values must be positive and are generally in the range of `0.00001` ( `1e-5` ) to `0.01` ( `1e-2` ). A higher learning rate can speed up training, but can cause the optimizer to overshoot and miss optimal solutions. Conversely, a lower learning rate ensures more stable and precise convergence but can make training much slower. If you do not specify this option, the system automatically selects a learning rate and adjusts it during training using the 1Cycle learning schedule. Specifying a learning rate disables automatic adjustment and instead uses a fixed learning rate value.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`maxInitParamValue` — If you set this option, the value must be a floating-point number. Sets the maximum for initial parameter values in the optimization algorithm. The default value is `1` .

`metrics` — If you set this option to `true` , the model calculates the average value of the loss function.

`minInitParamValue` — If you set this option, the value must be a floating-point number. Sets the minimum for initial parameter values in the optimization algorithm. The default value is `-1` .

`normalize` — If you set this option to `true`, this option applies z-score normalization to inputs by default, storing means and standard deviation, and automatically applying them at inference. The default value is `true`.

`numEpochs` — If you set this option, the value must be a positive `integer` type representing the maximum number of epochs, or full passes, during training through the entire data set. If you do not specify this option, the default maximum is `200`, but training typically stops earlier due to automatic early stopping when the model has converged.

`outputActivationFunction` — If you set this option, the values are `linear`, `relu` (rectified linear unit), `leakyrelu` (leaky rectified linear unit), `tanh` (hyperbolic tangent function), or `sigmoid` (fast sigmoid approximation). Different activation functions have different output ranges. The chosen activation function should match the dependent variable of your data. For example, if the dependent variable can be anything, then choose the `linear` value. If the dependent variable is always positive, then choose the `relu` value. If your outputs range from -1 to 1 or you perform hinge loss classification, `tanh` is a good option because the hyperbolic tangent function has the same range. But, if your outputs range from 0 to 1 or you perform log loss classification, `sigmoid` is a better choice for the same reason. This option defaults to `linear`. The option only sets the activation function for the output layer.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`randomSeed` — If you set this option, the value must be a positive `integer` type representing the seed for the random number generator the system uses for weight initialization. Setting this option makes model training deterministic (given the same data and options). If you do not specify this option or set it to `0`, the system uses a non-deterministic random seed.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`useSoftmax` — If you set this option to `true`, the model applies the softmax function to the output of the output layer before computing the loss function. The default value is `true` if you set the `lossFunction` option to `cross_entropy_loss`, and `false` otherwise.

# Multiple Linear Regression

## Model Options

### Optional

`convergenceTolerance` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `double` type that represents the relative convergence threshold for the Fast Iterative Shrinkage-Thresholding Algorithm (FISTA) optimizer. The optimizer stops when the relative change in coefficients between iterations falls below this value. This option only applies when you set the `lassoCoefficient` option to a positive value. The default value is `0.000001` ( `1e-6` ).

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`fitIntercept` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option to `false`, the model does not fit a y-intercept, forcing the regression through the origin. This option is equivalent to setting `yIntercept` to `0`, and you cannot combine them. The default value is `true`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`gamma` — If you set this option, the option must be a matrix. The value represents a Tikhonov gamma matrix used for regularization. For details, see **Tikhonov regularization**. The model uses this option for ridge regression.

`huberConvergenceTolerance` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `double` type that represents the convergence tolerance for Huber iteratively reweighted least squares (IRLS) iterations. The algorithm stops when the maximum coefficient change between iterations falls below this value; if the algorithm reaches `huberMaxIterations` first, training succeeds with a warning logged but no error returned. This option only applies when you set the `lossFunction` option to `'huber'`. The default value is `1e-6`.

`huberDelta` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `double` type that represents the Huber loss threshold expressed as a multiple of the residual scale (σ). Residuals smaller than `delta * σ` use squared loss; residuals larger use linear loss. The model estimates σ from the initial OLS fit and refreshes it each IRLS iteration via the weighted residual standard deviation, so a delta of `1.35` matches the convention used by scikit-learn's `HuberRegressor.epsilon` and Spark's `HuberAggregator`. This option only applies when you set the `lossFunction` option to `'huber'`. The default value is `1.35`.

`huberMaxIterations` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `integer` type that represents the maximum number of Huber IRLS iterations. If the algorithm has not converged within this many iterations, training succeeds with a warning logged but no error returned. This option only applies when you set the `lossFunction` option to `'huber'`. The default value is `20`.

`lassoCoefficient` — (BETA. This option is part of an in-development feature and is subject to change.) If you specify this option, the value must be a nonnegative `double`. This option adds L1 (lasso) regularization, which encourages sparse coefficients by driving some toward exactly zero. When you set this option to a positive value, the model uses the FISTA optimizer instead of the closed-form normal equation. When `normalize=true` (the default), the penalty is applied in standardized space and the persisted coefficients are un-scaled to the original units, matching scikit-learn's `Lasso(normalize=True)` convention. You can combine this option with the

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`ridgeCoefficient` option for elastic net regularization. You cannot combine this option with the `gamma` option. The default value is `0.0` (no L1 regularization).

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`lossFunction` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be either `'squared_error'` or `'huber'`. When you set this value to `'huber'`, the model uses Huber loss with iteratively reweighted least squares (IRLS), which is robust to outliers. Huber loss cannot be combined with the `lassoCoefficient`, `gamma`, or `weighted` options, and forces `normalize` to `false` because IRLS requires raw-scale residuals. Huber loss IS compatible with the `ridgeCoefficient` and `fitIntercept` options. The default value is `'squared_error'`.

`maxIterations` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `integer` type that represents the maximum number of FISTA iterations. This option only applies when the `lassoCoefficient` option is set to a positive value. The default value is `1000`.

`metrics` — If you set this option to `true`, the model collects quality metrics such as the coefficient of determination (R-squared), the adjusted coefficient of determination, and the root mean squared error (RMSE). The default value is `false`.

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. The default value is `true`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`ridgeCoefficient` — (BETA. This option is part of an in-development feature and is subject to change.) If you specify this option, the value must be a nonnegative `double`. This option adds L2 (ridge) regularization to the normal equation by adding this value

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

times the identity matrix to the X-transpose-X (Gram) matrix before inversion. Larger values shrink the coefficients more toward zero. When `normalize=true` (the default), the penalty is applied in standardized space and the persisted coefficients are un-scaled to the original units, matching scikit-learn's `Ridge(normalize=True)` convention. The default value is `0.0` (no regularization). You can combine this option with the `gamma` option or with the `lassoCoefficient` option for elastic net regularization.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`threshold` — If you set this option, the option enables soft thresholding. The value must be a positive number. After the model calculates the coefficients, if any coefficients exceed the threshold value, the model subtracts the threshold value from those coefficients. If any coefficients are less than the negation of the threshold value, the model adds the threshold value to the coefficients. For any coefficients that are between the negative and positive threshold values, the model sets the coefficients to zero.

`weighted` — If you set this option to `true`, the model performs weighted least squares regression, where each sample has a weight or importance associated with it. In this case, the table contains an additional numeric column after the dependent variable, which contains the weight for the sample. The default value is `false`.

`yIntercept` — If you set this option, then the option must be a numeric value. The system forces the specific y-intercept (i.e., the model value when `x` is zero).

# Naive Bayes

## Model Options

### Optional

`continuousFeatures` — If you set this option, the value must be a comma-separated list of the feature indexes that are continuous numeric variables. Indexes start with 1. In the default state, the model considers no features as continuous.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`metrics` — If you set this option to `true`, the model calculates the percentage of samples correctly classified by the model and saves this information in a system catalog table. The default value is `false`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

# Nonlinear Regression

## Model Options

### Required

`function` — Specify the name of the function to fit the data in SQL syntax. Use `a1, a2, …` to refer to the parameters for optimization. Use `x1, x2, …` to refer to the input features. The model does not allow some SQL functions. The model allows only scalar expressions that can be represented internally as postfix expressions. Most notably, the model does not allow some functions that are rewritten as CASE statements (like

`least()` and `greatest()`). If your function is not allowed, the model displays an error message.

`numParameters` — Specify this option as a positive integer. This value specifies the number of different parameters to optimize, i.e., how many different `aN` variables there are in the user-specified function.

## Optional

`adamBeta1` — If you set this option, the option represents the value of $\beta_1$ in the Adam optimization algorithm. For higher values of this option, training is less noisy but takes longer to converge. The default value is `0.9`.

`adamBeta2` — If you set this option, the option represents the value of $\beta_2$ in the Adam optimization algorithm. For higher values of this option, training is less noisy but takes longer to converge. The default value is `0.99`.

`adamEpsilon` — If you set this option, the option represents the value of $\varepsilon$ in the Adam optimization algorithm. For higher values of this option, training is more numerically stable but takes longer to converge. The default value is `1e-7`.

`constraints` — If you set this option, the value must be a SQL Boolean predicate over the parameter variables `a1, a2, …, aN`. During training, the model rejects every proposed parameter step that would violate the predicate. The LM optimizer increases its damping factor, and the Adam optimizer skips the update. The predicate can use any Boolean SQL composition (AND, OR, NOT, BETWEEN, comparisons) but cannot reference feature variables (`x1, x2, …`) or the dependent variable (`y`). Referencing these variables causes the `CREATE MLMODEL` SQL statement to fail with a validation error. If the optimizer rejects the number of proposed steps that you specify using the `maxConsecutiveRejections` option in a row without an accept, training terminates with `constraint_infeasible = true` in `sys.nonlinear_regression_models` instead of converging. The system persists the constraint string with the model and shows it in the `sys.nonlinear_regression_models` system catalog table.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`finiteDifferenceH` — If you set this option, the value must be a `double` type representing the step size ( `h` ) for approximating gradients using the finite difference method. The model uses this value only if analytical gradients are not active. This value should generally be a small positive number, typically from `0.0001` ( `1e-4` ) to `0.0000001` ( `1e-7` ). The default value is `0.00001` ( `1e-5` ).

`gradientClipThreshold` — If you set this option, the value must be a `double` that represents the gradient norm threshold for clipping. When the overall gradient norm exceeds this threshold, the system scales all gradient components uniformly to preserve direction. This operation prevents issues with exploding gradients in unstable loss landscapes. Set this value to 0 or a negative value to disable gradient clipping. The default value is `1000000` ( `1e6` ).

`lassoCoefficient` — If you specify this option, the value must be a `double` data type. This option is the lasso coefficient for the loss function. The default behavior is the function ignores this option, effectively setting this option to `0.0`.

`learningRate` — If you set this option, the value must be a `double` type representing the base learning rate for the Adam (Adaptive Moment Estimation) machine learning optimizer. Adam adapts this rate individually for each parameter during training. A common starting point for Adam is `0.001` ( `1e-3` ). Valid values must be positive and are generally in the range of `0.00001` ( `1e-5` ) to `0.01` ( `1e-2` ). A higher learning rate can speed up training, but can cause the optimizer to overshoot and miss optimal solutions. Conversely, a lower learning rate ensures more stable and precise convergence but can make training much slower. If you do not specify this option, the system automatically selects a learning rate and adjusts it during training using the 1Cycle learning schedule. Specifying a learning rate disables automatic adjustment and instead uses a fixed learning rate value.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

`logRejections` — If you set this option to `true`, the database emits an `INFO`-level log line for every constraint-rejected step during training. This option only takes effect when you set the `constraints` option. The default value is `false`.

`lossFunction` — If you set this option, the option indicates to the nonlinear optimizer the loss function to use on a per-sample basis. Then, the actual loss function is the sum of this function applied to all samples. The model should use the variable `y` to refer to the dependent variable in the training data and the variable `f` to refer to the computed estimate for the specified sample. The default is the least squares function, which you can specify as `(f-y)*(f-y)`.

`maxConsecutiveRejections` — If you set this option, the value must be a positive `integer` type representing the number of consecutive constraint-rejected steps that trigger termination during training with `constraint_infeasible = true` in `sys.nonlinear_regression_models`. This option only takes effect when you set the `constraints` option. Larger values let the optimizer probe further along a tightly-binding constraint boundary; smaller values surface infeasible problems faster. The accept and reject counter resets to zero on every accepted step. The default value is `50`.

`maxInitParamValue` — If you specify this option, the value must be a floating-point number. This option sets the maximum for initial parameter values in the optimization algorithm. The default value is `1`.

`metrics` — If you set this option to `true`, the model calculates the coefficient of determination (R-squared), the adjusted R-squared, and the root mean squared error (RMSE). However, the model calculates these quality metrics using the least squares loss function, and not the user-specified loss function, because these metrics only make sense for least squares. The default value is `false`

`minInitParamValue` — If you specify this option, the value must be a floating-point number. This option sets the minimum for initial parameter values in the optimization algorithm. The default value is `-1`.

`numEpochs` — If you set this option, the value must be a positive `integer` type representing the maximum number of epochs, or full passes, during training through the entire data set. If you do not specify this option, the default maximum value is `200`

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

for Adam optimization or `100` for Levenberg-Marquardt, but training typically stops earlier due to automatic early stopping when the model has converged.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`randomSeed` — If you set this option, the value must be a positive `integer` type representing the seed for the random number generator the system uses for weight initialization. Setting this option makes model training deterministic (given the same data and options). If you do not specify this option or set it to `0`, the system uses a non-deterministic random seed.

`ridgeCoefficient` — If you specify this option, the value must be a `double` data type. This option is the ridge coefficient for the loss function. The default behavior is the function ignores this option, effectively setting this option to `0.0`.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

# Polynomial Regression

## Model Options

### Required

`order` — This option is the degree of the polynomial and must be set to a positive integer.

### Optional

`convergenceTolerance` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `double` type that represents the relative convergence threshold for the Fast Iterative Shrinkage-Thresholding Algorithm (FISTA) optimizer. The optimizer stops when the relative change in coefficients between iterations falls below this value. This option only applies when you set the `lassoCoefficient` option to a positive value. The default value is `0.000001` ( `1e-6` ).

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`fitIntercept` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option to `false`, the model does not fit a y-intercept, forcing the regression through the origin. This option is equivalent to setting `yIntercept` to `0`, and you cannot combine them. The default value is `true`.

`gamma` — If you specify this option, the value must be a matrix. The value represents a Tikhonov gamma matrix that is used for regularization. For details, see **Tikhonov regularization**.

`huberConvergenceTolerance` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `double` type that represents the convergence tolerance for Huber iteratively reweighted least squares (IRLS) iterations. The algorithm stops when the maximum coefficient change between iterations falls below this value; if the algorithm reaches `huberMaxIterations` first, training succeeds with a warning logged but no error returned. This option only applies when you set the `lossFunction` option to `'huber'`. The default value is `1e-6`.

`huberDelta` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `double` type that represents the Huber loss threshold expressed as a multiple of the residual scale (σ).

Residuals smaller than `delta * σ` use squared loss; residuals larger use linear loss. The model estimates σ from the initial OLS fit and refreshes it each IRLS iteration via the weighted residual standard deviation, so a delta of `1.35` matches the convention used by scikit-learn's `HuberRegressor.epsilon` and Spark's `HuberAggregator`. This option only applies when you set the `lossFunction` option to `'huber'`. The default value is `1.35`.

`huberMaxIterations` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `integer` type that represents the maximum number of Huber IRLS iterations. If the algorithm has not converged within this many iterations, training succeeds with a warning logged but no error returned. This option only applies when you set the `lossFunction` option to `'huber'`. The default value is `20`.

`interactionOnly` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option to `true`, the model includes only interaction terms in the polynomial expansion. Interaction terms are products of distinct features where no single feature has a power greater than 1. For example, with three features and order 2, the model includes `x1*x2` and excludes `x1^2`. The default value is `false`.

`lassoCoefficient` — (BETA. This option is part of an in-development feature and is subject to change.) If you specify this option, the value must be a nonnegative `double`. This option adds L1 (lasso) regularization, which encourages sparse coefficients by driving some toward exactly zero. When you set this option to a positive value, the model uses the FISTA optimizer instead of the closed-form normal equation. When `normalize=true` (the default), the penalty is applied in standardized space and the persisted coefficients are un-scaled to the original units, matching scikit-learn's `Lasso(normalize=True)` convention. You can combine this option with the `ridgeCoefficient` option for elastic net regularization. You cannot combine this option with the `gamma` option. The default value is `0.0` (no L1 regularization).

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`lossFunction` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be either `'squared_error'` or `'huber'`. When you set this value to `'huber'`, the model uses Huber loss with iteratively reweighted least squares (IRLS), which is robust to outliers. Huber loss cannot be combined with the `lassoCoefficient`, `gamma`, or `weighted` options, and forces `normalize` to `false` because IRLS requires raw-scale residuals. Huber loss IS compatible with the `ridgeCoefficient` and `fitIntercept` options. The default value is `'squared_error'`.

`maxIterations` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `integer` type that represents the maximum number of FISTA iterations. This option only applies when you set the `lassoCoefficient` option to a positive value. The default value is `1000`.

`metrics` — If you set this option to `true`, the model collects quality metrics such as the coefficient of determination (R-squared), the adjusted coefficient of determination, and the root mean squared error (RMSE). The default value is `false`.

`negativePowers` — If you set this option to `true`, the model includes independent variables raised to negative powers. These variables are named Laurent polynomials. The model generates all possible terms such that the sum of the absolute value of the power of each term in each product is less than or equal to the order. For example, with two independent variables and the order set to `2`, the model is: `y = a1*x1^2 + a2*x1^-2 + a3*x2^2 + a4*x2^-2 + a5*x1*x2 + a6*x1^-1*x2 + a7*x1*x2^-1 + a8*x1^-1*x2^-1 + a9*x1 + a10*x1^-1 + a11*x2 + a12*x2^-1 + b`. The default value is `false`.

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. The default value is `true`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`ridgeCoefficient` — (BETA. This option is part of an in-development feature and is subject to change.) If you specify this option, the value must be a nonnegative `double`. This option adds L2 (ridge) regularization to the normal equation by adding this value times the identity matrix to the X-transpose-X (Gram) matrix before inversion. Larger values shrink the coefficients more toward zero. When `normalize=true` (the default), the penalty is applied in standardized space and the persisted coefficients are un-scaled to the original units, matching scikit-learn's `Ridge(normalize=True)` convention. The default value is `0.0` (no regularization). You can combine this option with the `gamma` option or with the `lassoCoefficient` option for elastic net regularization.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`threshold` — This option enables soft thresholding. If you specify this option, then the option must be a positive numeric value. After the model calculates the coefficients, if any of them are greater than the threshold value, the threshold value is subtracted from them. If any coefficients are less than the negation of the threshold value, the model adds the threshold value to them. For any coefficients that are between the negative and positive threshold values, the model sets those coefficients to zero.

`weighted` — If you set this option to `true`, the model performs weighted least squares regression, where each sample has an associated weight. When weighted, there is an extra numeric column after the dependent variable that has the weight for the sample. The default value is `false`.

`yIntercept` — If you set this option, then the option must be a numeric value. The system forces the specific y-intercept (i.e., the model value when `x` is zero).

# Principal Component Analysis

## Model Options

### Optional

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`numComponents` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive integer specifying the number of principal components to retain. This value must be between 1 and the number of input features. If you do not set this option or set it to `0`, the model retains all components. This model retains components in order of decreasing explained variance.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`whiten` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option to `true`, the model scales each component score by the inverse square root of its eigenvalue, producing unit-variance outputs. This option is useful when downstream algorithms are sensitive to feature scale. The default value is `false`.

# Random Forest

## Model Options

### Required

`numChildren` — Number of child decision trees.

## Optional

`ROCNumSamples` — If you set the option, you must also set the `metrics` option. This positive integer indicates the number of samples for the model to use for the area under the ROC curve. The default value is the number of child decision trees.

`bootstrap` — If you set this option to `true`, the model uses bootstrap sampling with replacement, meaning the model trains each tree in the random forest on a random subset of the data (either the `rowsPerChild` or `fractionSelected` option sets the exact number of rows), and the same row can appear multiple times in each tree. If you set this option to `false`, this option does not use replacement, meaning each row can appear at most once per tree. The default value is `false`.

`continuousFeatures` — If you set this option, the value must be a comma-separated list of the feature indexes that are continuous numeric variables. Indexes start with 1. In the default state, the model considers no features as continuous.

`distinctCountLimit` — If you set this option, the value must be a positive integer. This value limits how many distinct values a non-continuous feature and the label can contain. The default value is `256`.

`doPrune` — If you set this option to `true`, the model uses Pessimistic Error Pruning (PEP) to prune the tree after training. The default value is `false`.

`enableResplits` — If you set this option, the value must be a `boolean` type that determines if the tree can reuse the same continuous feature multiple times along a single branch (e.g., split on `x1 < 7` and later `x1 < 3`). This action can capture more complex, range-specific relationships. The default value is `true`, meaning that continuous features remain available for additional splits after use, thereby allowing the tree to create more complex decision boundaries. If you set this option to `false`, the model marks continuous features as exhausted after their first use, and the model cannot use them again in subsequent splits in the same tree. The model passes this option directly to the child decision trees.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`featureSubsetStrategy` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the model passes this option directly to the child decision trees. The option specifies how many features the child decision trees should consider at each split from the still-available features. When this value is higher, the model has higher accuracy and lower variance, but takes longer to train. You can specify this option either as an integer (e.g., `4`, meaning consider up to four features at each split) or one of these values: `all` (checks every feature), `sqrt` (checks up to the square root of the number of total features), `log2` (checks up to the base-2 logarithm of the number of total features), and `one-third` (checks up to one-third of the number of total features). The default value is `all`.

`fractionSelected` — If you set this option, the option represents the proportion of rows the model uses to train each child model. The value is a `double` that must be in the interval (0, 1]. You cannot set this option if you also set the `rowsPerChild` option to a positive value. The default behavior is that the model uses all available rows.

`inputsPerChild` — If you set this option, the option specifies the number of features for the creation of each child decision tree. The default value is the number of features you specify for the forest divided by 3 and rounded up.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`maxCellsToFetch` — If you set this option, the model passes this option directly to the child decision trees. If you set this option, the value must be a positive integer. Controls the chunking behavior when fetching feature values during model training. The limit represents the maximum number of data cells (calculated as the number of columns × number of rows) that the system can fetch in a single operation, not a byte limit. When the expected data size exceeds this threshold, the algorithm switches to database-based processing using SQL queries instead of in-memory processing. The default value is `33,554,432` cells (calculated as `32 × 1024 × 1024`).

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`maxChildThreads` — If you set this option, the value must be an `integer` type representing the maximum number of threads each child decision tree can use. The default value is `1`.

`maxDepth` — If you set this option, the value must be a positive integer. This value sets the maximum allowable depth of the decision tree. The default value is `3`.

`maxLeafNodes` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be an integer greater than or equal to `2`. The model passes this option directly to the child decision trees. The value caps the number of leaf nodes in each child tree during its depth-first build (it is a soft cap rather than best-first growth). The default value is unspecified, which means there is no limit on the number of leaf nodes.

`maxThreads` — If you set this option, the option specifies the maximum number of parallel threads to use while the model trains decision trees. This value must be a positive integer. The default value is `16`.

`metrics` — If you set this option to `true`, the model also calculates the percentage of samples that are correctly classified by the model for the random forest and saves this information in a system catalog table. The default value is `false`.

`minImpurityDecrease` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a non-negative `double`. The child decision tree splits only if the decrease in impurity is greater than or equal to this value. The model passes this option directly to the child decision trees. The default value is `0.0`.

`minSamplesLeaf` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive integer. This value sets the minimum number of samples required in a leaf node. The model passes this option directly to the child decision trees. The default value is `1`.

`minSamplesSplit` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be an integer greater than or equal to `2`. This value sets the minimum number of samples required to split a node. The model passes this option directly to the child decision trees. The default value is `2`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`numSplits` — If you set this option, the value must be an `integer` type greater than 1. This value sets the maximum number of binary branches a continuous feature can consider. The default value is `32`.

`oobScore` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option to `true`, the model computes the Out-of-Bag (OOB) score after training. The OOB score estimates model accuracy using only the samples not included in the bootstrap sample of each tree. This score provides a built-in validation metric without requiring a separate test set. This option requires that you set the `bootstrap` option to `true` as well. The default value is `false`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`requiredFeatures` — If you set this option, the option must be a comma-separated list of integers as strings representing specific features where the first feature has the value `1`. The model uses these features in every decision tree in the forest. The default behavior is that the decision tree in the forest can train on any feature in the list.

`rowsPerChild` — If you set this option to a positive integer, the number represents the number of rows (from a random sample) to use for each decision tree. If you set this option to `0`, each child uses all available rows. The default value is `0`. You cannot set this option to a positive value if you also set the `fractionSelected` option.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`skipLimitCheck` — If you set this option to `true`, the model skips cardinality checks that throw errors when columns have too many values. The limit that this option checks is the same one specified by the `distinctCountLimit` option. This option defaults to `false`.

`splitMetric` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the option controls which function the model uses to

evaluate the quality of a split during tree construction. The model passes this option directly to the child decision trees. Supported options are: `gini_impurity` (measures impurity based on class distributions), `entropy` (measures impurity using information entropy), and `hellinger` (uses the Hellinger distance, which requires exactly two output classes). The default value is `gini_impurity`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`weighted` — If you set this option, the model considers weights for labels. If you set this option value to `true`, you must specify an additional column as a `double` in the training data for label weights. Rows with the same labels must have the same weights. If you set this value to `auto`, the model calculates weights automatically by weighting each label according to the ratio of the count of the most frequent label to the count of the specified label. As a result, the most frequent label has a weight of `1.0`, and the other label weights are higher. This option defaults to `false`, which means all labels have equal weight.

# Regression Tree

## Model Options

### Optional

`continuousFeatures` — If you set this option, the value must be a comma-separated list of the feature indexes that are continuous numeric variables. Indexes start with 1. In the default state, the model considers no features as continuous.

`distinctCountLimit` — If you set this option, the value must be a positive integer. This value sets the limit for the number of distinct values a non-continuous feature and the label can contain. This option defaults to `256`.

`enableResplits` — If you set this option, the value must be a `boolean` type that determines if the tree can reuse the same continuous feature multiple times along a single branch (e.g., split on `x1 < 7` and later `x1 < 3`). This action can capture more complex, range-specific relationships. The default value is `true`, meaning that continuous features remain available for additional splits after use, which allows the

tree to create more complex decision boundaries. When you set this option to `false`, the model marks continuous features as exhausted after their first use, and the model cannot use them again in subsequent splits in the same tree.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`featureSubsetStrategy` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the option specifies how many features the regression tree should consider at each split from the still-available features. When this value is higher, the model has a higher accuracy and lower variance, but takes longer to train. You can specify this option either as an integer (e.g., `4`, meaning consider up to four features at each split) or one of these values: `all` (check every feature), `sqrt` (check up to the square root of the number of total features), `log2` (check up to the base-2 logarithm of the number of total features), and `one-third` (check up to one-third of the number of total features). The default value is `all`.

`maxCellsToFetch` — If you set this option, the value must be a positive integer. Controls the chunking behavior when fetching feature values during model training. The limit represents the maximum number of data cells (calculated as the number of columns × number of rows) that the system can fetch in a single operation, not a byte limit. When the expected data size exceeds this threshold, the algorithm switches to database-based processing using SQL queries instead of in-memory processing. The default value is `33,554,432` cells (calculated as `32 × 1024 × 1024`).

`maxDepth` — If you set this option, the value must be a positive integer. This value sets the maximum allowable depth of the decision tree (the maximum number of features to split on). The default is unspecified, which means there is no maximum depth.

`maxLeafNodes` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be an integer greater than or equal to `2`. This value caps the number of leaf nodes in the regression tree during the standard

depth-first build. When the tree reaches this limit, the model stops queuing further splits and converts pending nodes to leaves; this is a soft cap rather than the best-first growth, so the resulting tree might differ from a best-first tree of the same leaf budget. The default value is unspecified, which means there is no limit on the number of leaf nodes.

`maxRows` — If you set this option, the value must be a positive integer. This option limits the number of rows used for model training by creating a snapshot table with only the specified number of rows from the input query. When this option is unspecified, the model trains using all rows from the input query.

`maxThreads` — If you set this option, the value must be a positive integer. This value indicates the maximum number of parallel threads to use while the model trains. The default value is `2`.

`metrics` — If you set this option to `true`, the model also calculates the percentage of samples correctly classified by the model and saves this information in a system catalog table. The default value is `false`.

`minImpurityDecrease` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a non-negative `double`. The tree splits only if the decrease in impurity (the difference between the parent node impurity and the weighted sum of child node impurities, measured by variance) is greater than or equal to this value. The default value is `0.0`, meaning the model accepts all splits that reduce variance.

`minSamplesLeaf` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive integer. This value sets the minimum number of samples required in a leaf node. The model rejects any split that creates a child node with fewer samples than this value, making the node a leaf instead. The default value is `1`, meaning every leaf must have at least one sample.

`minSamplesSplit` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be an integer greater than or equal to `2`. This value sets the minimum number of samples required to split a node. Nodes with fewer samples than this value become leaves. The default value is `2`.

`numSplits` — If you set this option, the value must be an integer greater than 1. This value sets the maximum number of binary branches a continuous feature can consider. The default value is `32`.

`queryInternalParallelism` — If you set this option, the database appends the `USING PARALLELISM = <value>` clause to all intermediate SQL queries the model executes during training, where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`resplitDepth` — If you set this option, the value must be an `integer` type that sets the maximum depth at which tree nodes can be re-split during optimization. Controls how deep the algorithm searches for better split points. The default value is `6`.

`resplitThreshold` — If you set this option, the value must be a `decimal` type that sets the minimum improvement threshold required to trigger a re-split operation. Lower values (e.g., `0.01`) allow more aggressive re-splitting but can increase training time. Higher values (e.g., `1.0`) require larger improvements to trigger re-splits. The default value is `0.1`.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`skipLimitCheck` — If you set this option to `true`, the model skips cardinality checks that throw errors when columns have too many values. The limit that this option checks is the same one that you specify using the `distinctCountLimit` option. The default value is `false`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

# Simple Linear Regression

## Model Options

### Optional

`fitIntercept` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option to `false`, the model does not fit a y-intercept, forcing the regression through the origin. This option is equivalent to setting `yIntercept` to `0`, and you cannot combine them. The default value is `true`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`metrics` — If you set this option to `true`, the model collects quality metrics such as the coefficient of determination (R-squared) and the root mean squared error (RMSE). The default value is `false`.

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. The default value is `true`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`ridgeCoefficient` — (BETA. This option is part of an in-development feature and is subject to change.) If you specify this option, the value must be a nonnegative `double`. This option adds L2 (ridge) regularization to the normal equation by adding this value times the identity matrix to the X-transpose-X (Gram) matrix before inversion. Larger values shrink the coefficients more toward zero. When `normalize=true` (the default), the penalty is applied in standardized space and the persisted coefficients are un-scaled to the original units, matching scikit-learn's `Ridge(normalize=True)` convention. The default value is `0.0` (no regularization).

`threshold` — This option enables soft thresholding. If you specify this option, then the option must be a positive numeric value. After the model calculates the coefficients, if any are greater than the threshold value, the threshold value is subtracted from them. If any coefficients are less than the negation of the threshold value, the model adds the

© 2026 Ocient, Inc

threshold value to them. For any coefficients that are between the negative and positive threshold values, the model sets those coefficients to zero.

`yIntercept` — If you set this option, then the option must be a numeric value. The system forces the specific y-intercept (i.e., the model value when `x` is zero).

# Stacking

## Model Options

### Required

`levelZeroModels` — This option specifies the level-0 child models of the stacking model. You must specify this value as a JSON array, where each object in the array has the four fields `type` (required), `name`, `options`, `ignoreColumn`, and `extraCallArguments`.

### Optional

`classLabels` — (BETA. This option is part of an in-development feature and is subject to change.) Comma-separated list of distinct class labels for weighted stacking classification. If you set this option with the `weights` option, the model uses weighted voting for classification rather than weighted averaging. The model automatically detects class labels from training data when you specify the `weights` option, and you set the `hasLabelColumn` option to `true`.

`extraColumnCount` — If you set this option, the value must be an `integer` type that specifies how many non-feature columns there are in the input data. The default value is `0`.

`extraColumnsForLevelOne` — If you set this option, this option specifies the extra columns to pass as input columns to the level-1 model, in addition to the level-0 outputs. This value should be a comma-separated list of integers starting at 1, where each integer refers to an extra column index (must be between 1 and the `extraColumnCount` value). The default behavior is to pass none of the extra columns.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input

column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`hasLabelColumn` — If you set this option, the value must be a `boolean` type that specifies whether the input data includes a label column. The default value is `true`.

`levelOneModel` — (BETA. This option is part of an in-development feature and is subject to change.) This option specifies the level-1 child model of the stacking model. You must specify this value as a JSON object with the fields `type` (required), `name`, `options`, `ignoreColumn`, and `extraCallArguments`. This option is required unless you specify the `weights` option.

`maxThreads` — If you set this option, the option specifies the maximum number of parallel threads to use while the model trains. This value must be a positive integer. The default value is `16`.

`preservedColumnsForLevelOne` — If you set this option, this option specifies the columns from the original training data to pass as an input column to the level-1 model, in addition to the level-0 outputs. This value should be a comma-separated list of integers starting at 1. The default behavior is to preserve none of the columns.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`transitionEndTime` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, you must also set the `weights` and `transitionStartTime` options. The value must be a timestamp string in the format `YYYY-MM-DD HH:MM:SS`. Between the values of the `transitionStartTime` and `transitionEndTime` options, the weights shift linearly from their initial values to their

reversed values (e.g., `[1.0, 0.0]` transitions to `[0.0, 1.0]`). After the end time, the model uses the reversed weights permanently.

`transitionStartTime` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, you must also set the `weights` and `transitionEndTime` options. The value must be a timestamp string in the format `YYYY-MM-DD HH:MM:SS`. Before the start time, the model uses the initial weights. Between the values of the `transitionStartTime` and `transitionEndTime` options, the weights shift linearly from their initial values to their reversed values.

`weights` — (BETA. This option is part of an in-development feature and is subject to change.) Comma-separated list of weights for weighted stacking. If you set this option, the model uses a weighted combination of level-zero child predictions instead of a level-one meta-learner. Weights must be non-negative and sum to 1.0, and the number of weights must match the number of level-zero children. For classification tasks, set the `classLabels` option or ensure that you set the `hasLabelColumn` option to `true` for automatic detection.

# Support Vector Machine

## Model Options

### Optional

`ROCNumSamples` — If you set this option, you must specify a positive integer that represents the number of samples for the model to use when calculating the area under the ROC curve. You must also set the `metrics` option to `true`. The default value is `10`.

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`functionN` — By default, SVM uses a linear kernel. If you use a different kernel, you must provide a list of functions that are summed together, just like with linear combination regression. You must specify the first function using a key named 'function1'. Subsequent functions must use keys with names that use subsequent values of N. You must specify functions in SQL syntax and use the variables x1, x2, ... , xn to refer to the 1st, 2nd, and nth independent variables, respectively. You can specify the default linear kernel as: 'function1' → 'x1', 'function2' → 'x2', and so on. The model always adds a constant term equivalent to 'functionN' → '1.0' that you do not need to specify explicitly.

`kernel` — (BETA. This option is part of an in-development feature and is subject to change.) Named kernel convenience option that generates the appropriate `functionN` basis expressions automatically. Supported values are: `linear` (default; basis is the original feature set `x1, x2, ..., xn`), `poly` (basis is every monomial of total degree 1 through `kernelDegree`, e.g., for two features and `kernelDegree=2`, the basis is `x1, x2, x1*x1, x1*x2, x2*x2`), `rbf` (basis is `numRbfComponents` Random Fourier Feature approximations of the form `sqrt(2/D) * cos(w_j^T x + b_j)` where `w_j ~ N(0, 2 * kernelGamma * I)` and `b_j ~ Uniform(0, 2*pi)`), and `sigmoid` (basis is per-feature `tanh(kernelGamma * xi + kernelCoef0)`). Note that `poly`, `rbf`, and `sigmoid` are feature transformations rather than inner-product kernels in the kernel-trick sense, so they are not numerically equivalent to `SVC(kernel=...)` from scikit-learn with the same option values. SVM cannot combine the `kernel` option with explicit `functionN` options.

`kernelCoef0` — (BETA. This option is part of an in-development feature and is subject to change.) Independent term added inside the `tanh` of the per-feature transform of the `sigmoid` kernel as `tanh(kernelGamma * xi + kernelCoef0)`. Use this option only when you set the `kernel` option to `sigmoid`. The default value is `0.0`.

`kernelDegree` — (BETA. This option is part of an in-development feature and is subject to change.) Maximum monomial degree for the `poly` kernel. The generated basis includes every monomial of total degree 1 through `kernelDegree` (e.g., `kernelDegree=2` over features `x1, x2` produces `x1, x2, x1*x1, x1*x2, x2*x2`). Use this option only when you set the `kernel` option to `poly`. The value must be a positive integer. The default value is `3`. The total number of generated basis functions grows as `C(n+d, d) - 1` where `n` is the number of features and `d` is `kernelDegree`; the `maxKernelFunctions` guard rejects expansions that would exceed its limit.

© 2026 Ocient, Inc

`kernelGamma` — (BETA. This option is part of an in-development feature and is subject to change.) Coefficient for the `rbf` and `sigmoid` kernels. Use this option only when you set the `kernel` option to `rbf` or `sigmoid`. For `rbf`, controls the variance of the random projection weights `w_j ~ N(0, 2 * kernelGamma * I)`. For `sigmoid`, the per-feature multiplier inside `tanh(kernelGamma * xi + kernelCoef0)`. If you set this option to `0.0`, the SVM automatically substitutes `1.0 / n_features` (matching the legacy `gamma='auto'` behavior from scikit-learn, but not the same as the modern `gamma='scale'` default). The value must be a non-negative number. The default value is `0.0`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`maxKernelFunctions` — (BETA. This option is part of an in-development feature and is subject to change.) Maximum number of basis functions that the kernel convenience options (`poly` and `rbf`) are allowed to generate. If the polynomial or RBF expansion would produce more functions than this limit, SVM rejects the request. The value must be a positive integer. The default value is `5000`.

`metrics` — If you set this option to `true`, the model also calculates the percentage of samples that are correctly classified by the model and saves this information in a catalog table. This option defaults to `false`.

`normalize` — If you set this option to `true`, the model automatically computes the mean and standard deviation of each feature and uses them to normalize the data during training. Defaults to `true`.

`numEpochs` — If you set this option, the value must be a positive `integer` type representing the maximum number of IRLS iterations during training. The default value is `20`.

`numRbfComponents` — (BETA. This option is part of an in-development feature and is subject to change.) Number of Random Fourier Feature components for the RBF kernel. Use this option when you set the `kernel` option to `rbf`. The value must be a positive integer. Larger values yield a more accurate approximation at the expense of training time. The default value is `100`.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`randomSeed` — (BETA. This option is part of an in-development feature and is subject to change.) Random seed for reproducible kernel function generation (used by the RBF kernel for Random Fourier Features). The default value is `42`.

`regularizationCoefficient` — If you set this option, the value must be a valid floating-point number. Use this option to control the balance of finding a wide margin and minimizing incorrectly classified points in the loss function. A larger (and positive) value makes having a wide margin around the hypersurface more important relative to the incorrectly classified points. Because of how the system implements SVM, the values for this option are likely different than values used in other common SVM implementations. The default value is `1.0 / 1000000.0`.

`skipDropTable` — If you set this option to `false`, the database deletes any intermediate tables created during model training. If you set this option to `true`, the database prevents the deletion of any intermediate tables created during model training. The default value is `false`.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`weighted` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option to `true`, the model performs weighted SVM classification, where each sample has a weight or importance associated with it. In this case, the table includes an additional numeric column after the dependent variable that contains the sample weight. If you set this option to `auto`, the model automatically computes balanced class weights using the formula `weight_k = max_count / count_k`, where `max_count` is the count of the most-frequent class. The most-frequent class receives weight `1.0` and minority classes receive proportionally larger weights; relative weighting between classes is identical to the `class_weight='balanced'` from scikit-learn (only the absolute scale differs). The model applies the weight as a multiplier on the per-sample squared-hinge loss, equivalent to per-class regularization. The default value is `false`.

# Survival Regression

## Model Options

### Required

`eventColumn` — Specifies the name of the binary event-indicator column in the `SELECT` SQL statement for the training data. The column must contain `1` for an observed event and `0` for a censored observation. The column must be present in the `SELECT` statement with this exact name.

`timeColumn` — Specifies the name of the time-to-event or censoring time column in the `SELECT` SQL statement for the training data. The column type must be `DOUBLE PRECISION`, `BIGINT`, or `TIMESTAMP`. Values must be non-negative. The column must be present in the `SELECT` statement with this exact name.

### Optional

`aftDistribution` — If you set this option and you set the `family` option to `'aft'`, the value selects the parametric distribution. Supported values are `'weibull'` (default), `'lognormal'`, and `'loglogistic'`. When you set the `family` option to `'cox'`, the model ignores this option. The default value is `'weibull'`.

`convergenceTolerance` — If you set this option, the value must be a positive `double` type that represents the convergence threshold for the Newton-Raphson (Cox) or quasi-Newton (AFT) optimizer. The optimizer stops when the maximum absolute change in any coefficient between iterations falls below this value. The default value is `0.000001` ( `1e-6` ).

`family` — If you set this option, the value selects the survival regression family. Supported values are `'cox'` (Cox proportional hazards) and `'aft'` (accelerated failure time). The default value is `'cox'`.

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value ( `true` or `false` ). The default value is unspecified. In this case, the database does not add this clause.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`maxIterations` — If you set this option, the value must be a positive `integer` type that represents the maximum number of Newton-Raphson (Cox) or quasi-Newton (AFT) iterations. The default value is `100`.

`metrics` — If you set this option to `true`, the model computes survival metrics on the test data when you specify the `VALIDATE ON` clause. Otherwise, the model uses the training data. Metrics are the Concordance Index and the partial log-likelihood. The default value is `false`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`regParam` — If you set this option, the value must be a non-negative `double` type representing the L2 (ridge) regularization strength on the linear-predictor coefficients. Larger values shrink coefficients toward zero. The default value is `0.0` (no regularization).

`ties` — If you set this option and you set the `family` option to `'cox'`, the value selects how the model handles tied event times in the partial likelihood. Supported values are `'efron'` and `'breslow'`. When you set the `family` option to `'aft'`, the model ignores this option. The default value is `'efron'`.

# Undersampling

## Model Options

### Required

`classColumn` — (BETA. This option is part of an in-development feature and is subject to change.) The name of the column where the value defines the class for sampling. This column is required for both `random` and `stratified` strategies.

### Optional

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model

executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`samplingRatio` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value indicates the final majority or minority row count ratio relative to the target class. The value must be a positive `double`. The default value is `1.0` (balanced output). The value of `2.0` keeps roughly twice as many non-target rows per class as the target class. Under the `random` strategy, sampling is non-deterministic and result counts vary by approximately the square root of the expected count. Under the `stratified` strategy, the per-stratum row count is deterministic, with the specific rows chosen by random ordering within each stratum.

`strategy` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value indicates the sampling strategy as either `random` (independent Bernoulli sampling per row in each non-target class) or `stratified` (for each (non-target class, stratum) pair, the model keeps an exact count of rows proportional to the stratum size, with the specific rows chosen by random ordering within the stratum; this preserves the per-stratum class distribution and produces a deterministic per-stratum and overall row count). The default value is `random`. When you set this option to `stratified`, you must also set the `stratumColumn` option.

`stratumColumn` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value sets the name of the column that defines strata. This option is required when you set the `strategy` option to `stratified`. The model preserves the per-stratum class distribution within each non-target class. The default value is unspecified.

`targetClass` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value indicates the class label that defines the target row count. The default value is `auto`, in which case the model uses the smallest class as the target. You can also specify a class-label string, and the resulting target row count is the row count of that class.

# Vector Autoregression

## Model Options

### Required

`numLags` — Specify this option as a positive integer for the number of lags in the model.

`numVariables` — Specify this option as a positive integer for the number of variables in the model.

### Optional

`convergenceTolerance` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `double` type that represents the relative convergence threshold for the Fast Iterative Shrinkage-Thresholding Algorithm (FISTA) optimizer. The optimizer stops when the relative change in coefficients between iterations falls below this value. This option only applies when you set the `lassoCoefficient` option to a positive value. The default value is `0.000001` ( `1e-6` ).

`featureArray` — If you set this option to `true`, the model expects only one array-type input column instead of multiple columns of training data. Each array row in the input column must be the same size. The default value is `false`.

`featureArrayElements` — If you set this option, the `featureArray` option must be set to `true`. The value must be a comma-separated list of integers representing indexes of the input array to use starting at index 1. The system uses all indexes of the input array by default.

`lassoCoefficient` — (BETA. This option is part of an in-development feature and is subject to change.) If you specify this option, the value must be a nonnegative `double`. This option adds L1 (lasso) regularization, which encourages sparse coefficients by driving some toward exactly zero. When you set this option to a positive value, the model uses the FISTA optimizer instead of the closed-form normal equation. When `normalize=true` (the default), the penalty is applied in standardized space and the persisted coefficients are un-scaled to the original units, matching scikit-learn's `Lasso(normalize=True)` convention. You can combine this option with the

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`ridgeCoefficient` option for elastic net regularization. The default value is `0.0` (no L1 regularization).

`loadBalance` — If you set this option, the database appends the `USING load_balance_shuffle = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified option value (`true` or `false`). The default value is unspecified. In this case, the database does not add this clause.

`maxIterations` — (BETA. This option is part of an in-development feature and is subject to change.) If you set this option, the value must be a positive `integer` type that represents the maximum number of FISTA iterations. This option only applies when you set the `lassoCoefficient` option to a positive value. The default value is `1000`.

`metrics` — If you set this option to `true`, the function collects the metric for the coefficient of determination (R-squared). The default value is `false`.

`normalize` — If you set this option to `true`, the model uses auto-scaling to compute the mean and standard deviation of each input feature to normalize data during training, making training more numerically stable. The model then unscales parameters so the persisted model operates in the original units. The default value is `true`.

`queryInternalParallelism` — If you set this option, the database appends the `USING parallelism = <value>` clause to all intermediate SQL queries the model executes during training where `value` is the specified positive integer value. The default value is unspecified. In this case, the database does not add this clause.

`ridgeCoefficient` — (BETA. This option is part of an in-development feature and is subject to change.) If you specify this option, the value must be a nonnegative `double`. This option adds L2 (ridge) regularization to the normal equation by adding this value times the identity matrix to the X-transpose-X (Gram) matrix before inversion. Larger values shrink the coefficients more toward zero. When `normalize=true` (the default), the penalty is applied in standardized space and the persisted coefficients are un-scaled to the original units, matching scikit-learn's `Ridge(normalize=True)` convention. The default value is `0.0` (no regularization). You can combine this option with the `lassoCoefficient` option for elastic net regularization.

`suppressArrayLengthCheck` — If you set this option, the `featureArray` option must be set to `true`. The system skips checking that the array length is the same size for all rows in the input. The default value is `false`.

`threshold` — This option enables soft thresholding. If you specify this option, then the option must be a positive numeric value. After the model calculates the coefficients, if any of them are greater than the threshold value, the threshold value is subtracted from them. If any coefficients are less than the negation of the threshold value, the model adds the threshold value to them. For any coefficients that are between the negative and positive threshold values, the model sets those coefficients to zero.

# Math Functions and Operators

Reference for Ocient SQL math functions and operators, including arithmetic, trigonometry, logarithms, exponents, rounding, and numeric type conversions.

## Math Operators

Ocient® supports addition, subtraction, multiplication, and division between any two numeric types. Division involving two integral types always results in an integral type.

### Decimal Precision

These rules determine the precision `p` and scale `s` for the result of a specified expression that involves decimals `d1` and `d2`, with precisions `p1` and `p2`, and scales `s1` and `s2`:

| Operation | Precision | Scale |
|---|---|---|
| addition, subtraction | max( `s1` , `s2` ) + max( `p1` - `s1` , `p2` - `s2` ) + 1 | max( `s1` , `s2` ) |
| multiplication | `p1` + `p2` | `s1` + `s2` |
| division | *See note.* | max(6, `s1` + `p2` + 1) |

For division, the resulting precision is the minimum necessary to hold the whole number portion of the result. If that portion does not exist because the absolute value of the result is less than one, the resulting precision is one greater than the scale. For other operations, the result might still have a lower precision (but the same scale) than specified by these rules when the result would otherwise have a leading insignificant zero.

If the resulting precision exceeds 31, the database decreases both precision and scale until the precision is 31, except in division, where the minimal scale is always six. If the resulting precision still exceeds 31, the database truncates it to 31. The database returns an overflow error when the result exceeds the available integral portion of the result. When the database decreases the resulting scale, it truncates the excess fractional digits in the result.

## Math Operators for Time Intervals

Ocient supports math operators for time interval values (hour, minute, second, etc.), including when used with time-series data types such as TIME, TIMESTAMP, and DATE.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

You can use addition, subtraction, multiplication, and division on time intervals like any other numeric value.

> Division operations can produce inaccurate results because the system truncates the precision of the result to a whole number. For details, see **Decimal Precision**.

### Examples

#### Add Interval Value to Timestamp

This example uses the MINUTES cast function to add six minutes to the TIMESTAMP value returned from the TIMESTAMP cast function of the `'2023-04-05 12:15:05'` string.

SQL

```
SELECT TIMESTAMP('2023-04-05 12:15:05') + (MINUTES(6));
```

*Output*: `2023-04-05 12:21:05.000`

#### Add Fractional Interval Value to Timestamp

This example shows how division can produce an inaccurate result. The division operation in the example must produce a whole number. In other words, the system calculates two minutes as `5 / 2 = 2` instead of two and a half minutes as `5 / 2 = 2.5`.

SQL

```
SELECT TIMESTAMP('2023-04-05 12:15:05') + (MINUTES(5) / 2);
```

*Output*: `2023-04-05 12:17:05.000`

## Math Functions

These scalar math functions operate on a single value and return a single value. They can appear anywhere where an ordinary value or condition can appear.

For a list of common math symbols supported in Ocient, see **Math Operators**.

## ABS

Returns the absolute value of a specified floating-point number.

### Syntax

```SQL
ABS(x)
```

### Example

```SQL
SELECT ABS(-250.5);
```

*Output*: `250.5`

## ACOS

Returns the inverse cosine of a specified floating-point number.

### Syntax

```SQL
ACOS(x)
```

### Example

```SQL
SELECT ACOS(0.25);
```

*Output*: `1.318116071652818`

## ACOSH

Returns the hyperbolic arc-cosine of a specified floating-point number.

© 2026 Ocient, Inc

### Syntax

```
SQL

ACOSH(x)
```

### Example

```
SQL

SELECT ACOSH(2);
```

*Output*: `1.3169578969248166`

## ASIN

Returns the inverse sine of a specified floating-point number.

### Syntax

```
SQL

ASIN(x)
```

### Example

```
SQL

SELECT ASIN(0.25);
```

*Output*: `0.25268025514207865`

## ASINH

Returns the hyperbolic arc-sine of a specified floating-point number.

### Syntax

```sql
ASINH(x)
```

### Example

```sql
SELECT ASINH(2);
```

*Output*: `1.4436354751788103`

## ATAN

Returns the inverse tangent of a specified floating-point number.

### Syntax

```sql
ATAN(x)
```

### Example

```sql
SELECT ATAN(0.25);
```

*Output*: `0.24497866312686414`

## ATAN2

Returns the inverse tangent of two numeric, floating-point values.

### Syntax

```sql
ATAN2(x, y)
```

### Example

```sql
SELECT ATAN2(0.50, 1);
```

*Output*: `0.4636476090008061`

## ATANH

Returns the hyperbolic arc-tangent of a specified floating-point number.

### Syntax

```sql
ATANH(x)
```

### Example

```sql
SELECT ATANH(0.25);
```

*Output*: `0.25541281188299536`

## BICDF

The cumulative distribution function of the standard bivariate normal distribution, which returns the probability that a random sample of (A, B) is less than `x` and less than `y` ( `A <= x and B <= y` ). The correlation is set to `0` in the case where you specify two arguments only.

You can specify an optional `rho` coefficient to calculate the correlation.

For details, see the **bivariate cumulative distribution function**.

### Syntax

```
SQL

BICDF(x, y [, rho])
```

### Example

```
SQL

SELECT BICDF(1,2);
```

*Output*: `0.8222040420815764`

## BIPDF

The probability density function of the standard bivariate normal distribution returns the relative likelihood that a random sample would equal the specified values. The correlation is set to `0` in the case where you specify two arguments only.

You can specify an optional `rho` coefficient to calculate the correlation.

For details, see the **bivariate probability density function**.

### Syntax

```
SQL

BIPDF(x, y, [, rho])
```

### Example

```
SQL

SELECT BIPDF(1,2);
```

*Output*: `0.013064233284684893`

© 2026 Ocient, Inc

# BITFUNC

Performs a variety of bit operations.

The `char_func` can be any of these string literals: `'AND'`, `'OR'`, or `'XOR'`. This argument determines the bitwise operation that is performed on arguments `x` and `y`.

## Syntax

```
SQL

BITFUNC(char_func, x, y)
```

| Argument | Data Type | Description |
|---|---|---|
| `character_func` | `CHAR` | This argument determines the bitwise operation performed on arguments `x` and `y`.<br>Can be any of these string literals: `'AND'`, `'OR'`, or `'XOR'`.<br>To perform bit operations using a NOT operator, use the **BITNOT** function. |
| `x` | `INT` | A numeric value to be evaluated by the function. |
| `y` | `INT` | A numeric value to be evaluated by the function. |

## Example

```
SQL

SELECT BITFUNC('AND',11,12);
```

*Output*: `8`

## Example

```
SQL

SELECT BITFUNC('OR',11,12);
```

*Output*: `15`

### Example

```
SQL

SELECT BITFUNC('XOR',11,12);
```

*Output*: `7`

## BITAND

Alias for the **BITFUNC** syntax `BITFUNC('AND', x, y)`.

## BITNOT

Returns the bitwise negation of `integral_x`.

### Syntax

```
SQL

BITNOT(integral_x)
```

### Example

```
SQL

SELECT BITNOT(1);
```

*Output*: `-2`

## BITOR

Alias for the **BITFUNC** syntax `BITFUNC('OR', x, y)`.

## BITXOR

Alias for the **BITFUNC** syntax `BITFUNC('XOR', x, y)`.

## BOOLFUNC

Performs a Boolean logical evaluation on arguments `x` and `y`. Numbers equal to `0` evaluate to `false`, and numbers not equal to `0` evaluate to `true`.

### Syntax

```
SQL

BOOLFUNC(char_func, x, y)
```

| Argument | Data Type | Description |
|---|---|---|
| `char_func` | `CHAR` | This argument determines the Boolean operation performed on arguments `x` and `y`.<br>Can be any of these string literals: `'AND'`, `'OR'`, or `'XOR'`.<br>To perform operations using a NOT operator, use the **BOOLNOT** function. |
| `x` | `INT` | A numeric value for evaluation by the function. |
| `y` | `INT` | A numeric value for evaluation by the function. |

### Example

```
SQL

SELECT BOOLFUNC('AND',0,1);
```

*Output*: `false`

### Example

```
SQL

SELECT BOOLFUNC('OR',0,1);
```

*Output*: `true`

### Example

© 2026 Ocient, Inc

```sql
SELECT BOOLFUNC('XOR',0,1);
```

*Output*: `true`

## BOOLAND

Alias for the **BOOLFUNC** syntax `BOOLFUNC('AND', x, y)`.

## BOOLNOT

Returns the logical negation of the **BOOLFUNC** function. Numbers equal to `0` evaluate to `true`, and numbers not equal to `0` evaluate to `false`.

### Syntax

```sql
BOOLNOT(numeric_x)
```

### Example

```sql
SELECT BOOLNOT(0);
```

*Output*: `true`

## BOOLOR

Alias for the **BOOLFUNC** syntax `BOOLFUNC('OR', x, y)`.

## BOOLXOR

Alias for the **BOOLFUNC** syntax `BOOLFUNC('XOR', x, y)`.

## CBRT

Returns the cube root of the numeric value `x`.

### Syntax

```
SQL

CBRT(x)
```

### Example

```
SQL

SELECT CBRT(64);
```

*Output*: `4.0`

## CDF

The cumulative distribution function of the standard normal distribution. Returns the probability that a random sample is less than or equal to the specified value.

For details about the cumulative distribution function, see **Cumulative distribution function**.

### Syntax

```
SQL

CDF(x)
```

### Example

```
SQL

SELECT CDF(1.5);
```

*Output*: `0.9331927987311419`

## CEIL

Returns the nearest integer greater than or equal to `x`.

### Syntax

```sql
CEIL(x)
```

### Example

```sql
SELECT CEIL(23.45);
```

*Output*: `24.0`

## CEILING

Alias for CEIL.

## COS

Returns the cosine of `x`.

### Syntax

```sql
COS(x)
```

### Example

```sql
SELECT COS(2);
```

*Output*: `-0.4161468365471424`

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## COSH

Returns the hyperbolic cosine of `x`.

### Syntax

```
SQL

COSH(x)
```

### Example

```
SQL

SELECT COSH(2);
```

*Output*: `3.7621956910836314`

## COT

Returns the cotangent of `x`.

### Syntax

```
SQL

COT(x)
```

### Example

```
SQL

SELECT COT(2);
```

*Output*: `-0.45765755436028577`

## DEGREES

Returns the corresponding angle in degrees for `x` in radians.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

### Syntax

```
SQL

DEGREES(x)
```

### Example

```
SQL

SELECT DEGREES(1.5);
```

*Output*: `85.94366926962348`

## DIV

Returns the result of `x` divided by `y`. If `y` is zero, returns NULL.

### Syntax

```
SQL

DIV(x, y)
```

### Example

```
SQL

SELECT DIV(45, 9);
```

*Output*: `5`

## ERF

The error function is used for measurements that follow a normal distribution. Use this function to find the probability that the error of a single measurement lies between [-a, a]. For details about the error function, see **Error function**.

### Syntax

```sql
ERF(x)
```

### Example

```sql
SELECT ERF(8);
```

*Output*: `1.0`

## ERFC

The complement of the error function. `ERFC(x) = 1 - ERF(x)`.

### Syntax

```sql
ERFC(x)
```

### Example

```sql
SELECT ERFC(8);
```

*Output*: `1.1224297172982928E-29`

## EXP

Returns the exponential of `x` (e raised to the power of `x`).

### Syntax

```sql
EXP(x)
```

### Example

```sql
SELECT EXP(1);
```

*Output*: `2.718281828459045`

## FLOOR

Returns the nearest integer less than or equal to `x`.

### Syntax

```sql
FLOOR(x)
```

### Example

```sql
SELECT FLOOR(22.75);
```

*Output*: `22.0`

## GAMMA

Compute the gamma function of the specified value. For details about the gamma function, see the **Gamma function**.

### Syntax

```
SQL
GAMMA(x)
```

### Example

```
SQL
SELECT GAMMA(9.0);
```

*Output*: `40319.99999999999`

## HEXBINX

Returns the x-coordinate of the center of the nearest hexagonal bin to the point ( `x` , `y` ). Hexagonal bins have a side length of 1.

### Syntax

```
SQL
HEXBINX(x, y)
```

### Example

```
SQL
SELECT HEXBINX(5, 7);
```

*Output*: `4.5`

## HEXBINY

Returns the y-coordinate of the center of the nearest hexagonal bin to the point ( `x` , `y` ). Hexagonal bins have a side length of 1.

### Syntax

```sql
HEXBINY(x, y)
```

### Example

```sql
SELECT HEXBINY(5, 7);
```

*Output*: `7.794`

## IERF

The inverse of the ERF error function.

### Syntax

```sql
IERF(x)
```

### Example

```sql
SELECT IERF(0);
```

*Output*: `0.0`

## IERFC

The inverse of the complement of the error function.

### Syntax

```
SQL
IERFC(x)
```

### Example

```
SQL
SELECT IERFC(1);
```

*Output*: `0.0`

## LEAKYRELU

Returns the leaky rectified linear unit function of `x`.

If unspecified, the optional `numeric_value_slope` argument defaults to `0.01`.

### Syntax

```
SQL
LEAKYRELU(x [, numeric_value_slope] )
```

### Example

```
SQL
SELECT LEAKYRELU(-40);
```

*Output*: `-0.4`

## LEFT_SHIFT

Returns `x` shifted to the left by `y` bits. If `y` is less than 0, then `x` shifts to the right by the absolute value. The function throws an out-of-range error if you attempt a shift into the sign bit.

### Syntax

```sql
LEFT_SHIFT(x, y)
```

### Example

```sql
SELECT LEFT_SHIFT(1,2);
```

*Output*: `4`

## LN

Returns the natural logarithm of `x` (base e or 2.171828...).

### Syntax

```sql
LN(x)
```

### Example

```sql
SELECT LN(2);
```

*Output*: `0.6931471805599453`

## LOG2

Returns the base 2 logarithm of `x`.

### Syntax

```sql
LOG2(x)
```

### Example

```sql
SELECT LOG2(2);
```

*Output*: `1.0`

## LOG

Returns the base 10 logarithm of `x`.

The optional `base` argument specifies the numeral system to use. If unspecified, the function defaults to base 10.

### Syntax

```sql
LOG([ base,] x)
```

### Example

```sql
SELECT LOG(2);
```

*Output*: `0.3010299956639812`

## LOG_GAMMA

The natural logarithm of the absolute value of the gamma function.

### Syntax

```sql
LOG_GAMMA(x)
```

### Example

```sql
SELECT LOG_GAMMA(10);
```

*Output*: `12.80182748008147`

## MOD

Returns the remainder from `x` divided by `y`.

### Syntax

```sql
MOD(x, y)
```

### Example

```sql
SELECT MOD(12, 10);
```

*Output*: `2`

## PI

Returns the constant value of π.

### Syntax

```sql
PI()
```

### Example

```sql
SELECT PI();
```

*Output*: `3.141592653589793`

## PMOD

Returns the smallest non-negative equivalence class of `x` % `y`.

### Syntax

```sql
PMOD(x, y)
```

### Example

```sql
SELECT PMOD(12,10);
```

*Output*: `2`

## POWER

Returns `x` raised to the power of `y`. The return type `FLOAT` is returned for a `FLOAT` input, `DECIMAL` for `DOUBLE` input, and `BIGINT` otherwise.

### Syntax

```sql
POWER(x, y)
```

### Example

```sql
SELECT POWER(2, 4);
```

*Output*: `16`

## PROBIT

The inverse of the cumulative distribution function. The function accepts only decimal values between `0` and `1`.

For details about the probit function, see the **Probit model**.

### Syntax

```sql
PROBIT(x)
```

### Example

```sql
SELECT PROBIT(0.4);
```

*Output*: `-0.2533471031357998`

## RADIANS

Returns the corresponding angle in radians for `x` in degrees.

### Syntax

```sql
RADIANS(x)
```

### Example

```sql
SELECT RADIANS(2);
```

*Output*: `0.03490658503988659`

## RAND

Takes no argument and returns a random `DOUBLE` value in the range [0, 1).

### Syntax

```sql
RAND()
```

### Example

```sql
SELECT RAND();
```

*Output*: `0.6053105024272647`

## RELU

Returns the rectified linear unit function of `x`.

### Syntax

```sql
RELU(x)
```

### Example

```sql
SELECT RELU(-1);
```

*Output*: `0.0`

## RIGHT_SHIFT

Returns `x` shifted to the right by `y` bits. If `y` is less than 0, then `x` shifts to the left by the absolute value of `y` in bits. The function throws an out-of-range error if you attempt a shift into the sign bit.

### Syntax

```sql
RIGHT_SHIFT(x, y)
```

### Example

```sql
SELECT RIGHT_SHIFT(5,1);
```

*Output*: `2`

## ROUND

Returns `x` rounded to the nearest integer.

### Syntax

```sql
ROUND(x)
```

### Example

```sql
SELECT ROUND(12.49);
```

*Output*: `12.0`

## SIGN

Returns the positive (+1), zero (0), or negative (-1) sign of `x`.

### Syntax

```sql
SIGN(x)
```

### Example

```sql
SELECT SIGN(+12);
```

*Output*: `1`

### Example

```sql
select SIGN(0);
```

*Output*: `0`

### Example

```SQL
SELECT SIGN(-12);
```

*Output*: `-1`

## SIN

Returns the sine of `x`.

### Syntax

```SQL
SIN(x)
```

### Example

```SQL
SELECT SIN(2);
```

*Output*: `0.9092974268256817`

## SINH

Returns the hyperbolic sine of `x`.

### Syntax

```SQL
SINH(x)
```

### Example

```sql
SELECT SINH(2);
```

*Output*: `3.626860407847019`

## SQRT

Returns the square root of `x`.

### Syntax

```sql
SQRT(x)
```

### Example

```sql
SELECT SQRT(81);
```

*Output*: `9`

## SQUARE

Returns the square of `x`.

### Syntax

```sql
SQUARE(x)
```

### Example

```sql
SELECT SQUARE(7);
```

*Output*: `49`

## TAN

Returns the tangent of `x`.

### Syntax

```sql
TAN(x)
```

### Example

```sql
SELECT TAN(1.75);
```

*Output*: `-5.52037992250933`

## TANH

Returns the hyperbolic tangent of `x`.

### Syntax

```sql
TANH(x)
```

### Example

```sql
SELECT TANH(1.75);
```

*Output*: `0.9413755384972874`

## TO_BASE

Converts an integer value to its string representation in a specified base (radix).

### Syntax

```sql
TO_BASE(value, base)
```

| Argument | Data Type | Description |
|---|---|---|
| `value` | `BYTE`, `SMALLINT`, `INT`, `BIGINT` | The integer value to convert to the specified base. Can be positive or negative. |
| `base` | `BYTE`, `SMALLINT`, `INT`, `BIGINT` | The base (radix) for the conversion. Must be an integer between 2 and 36 (inclusive). For bases greater than 10, lowercase letters `(a-z)` represent digits 10 through 35 (e.g., `a` = 10, `b` = 11, and `z` = 35). |

### Examples

#### Convert to Binary (Base 2)

This example converts the decimal value `7` to its binary representation.

```sql
SELECT TO_BASE(7, 2);
```

*Output*: `111`

#### Convert to Octal (Base 8)

This example converts the decimal value `64` to its octal representation.

```sql
SELECT TO_BASE(64, 8);
```

*Output*: `100`

## TRUNC

Returns `x` truncated to `y` decimal places.

### Syntax

```sql
TRUNC(x,y)
```

### Example

```sql
SELECT TRUNC(1.23456,3);
```

*Output*: `1.234`

## TRUNCATE

Alias for TRUNC.

# Matrix Functions and Operators

Reference for Ocient SQL matrix functions and operators for constructing, multiplying, transposing, and inspecting matrix values used in analytics and ML.

In Ocient®, a matrix is a fixed-size, multi-dimensional array of `DOUBLE` values. Many OcientML™ models and feature representations are naturally expressed as matrices, making them a core building block for in-database machine learning.

Matrices help you:

- **Store dense numeric features** — Keep related numeric inputs together as a single matrix value instead of many scalar columns. This storage simplifies machine learning training and scoring queries.
- **Represent model internals and transformations** — Learned weights, intermediate layers, and linear transformations are often matrix-shaped. Keeping these as matrices in SQL lets more of the machine learning pipeline execute directly in Ocient.
- **Apply math and linear-algebra style operations in SQL** — Matrix functions and operators let you construct, inspect, and manipulate matrix values in the same queries that drive machine learning models and preprocessing steps.

For an overview of Ocient machine-learning capabilities, see **Machine Learning in Ocient**.

## Matrix Usage

To define a matrix data type in SQL, use the syntax `MATRIX[rows][columns]`, where the bracketed numbers specify the number of matrix rows and columns.

### Example

This example creates a basic table `matrix_example` with a matrix column `col_matrix` that contains matrices with two rows and three columns.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE TABLE matrix_example (
    id INT,
    col_matrix MATRIX[2][3] NOT NULL
);
```

Insert data for two matrices into the matrix column.

SQL

```
INSERT INTO matrix_example (id, col_matrix) VALUES
    (1, {{1, 2, 3}, {4, 5, 6}}),
    (2, {{0, 0, 0}, {7, 8, 9}});
```

For more DDL examples that use matrices, see **CREATE TABLE SQL Statement Examples**.

For details about working with matrix values, see **Data Types**.

# Matrix Functions

In the examples, `_R{}` and `_C{}` are vector notation, meaning `_R{ 1,2,3 }` is a row vector with values `1`, `2`, and `3`.

| Function | Syntax | Purpose | Example |
|---|---|---|---|
| Constructor | make_matrix_ixj(i, j, e_00, ..., e_ij) | Creates an `ixj` matrix with elements `e_00`, `…`, `e_ij` | make_matrix_1x3(1,3,1,2,3) |
| Constructor (2) | matrix_from_text(string) | Creates a matrix from the specified string | matrix_from_text('{ {1,2,3}, {1,2,3} }') |
| + (matrix addition) | matrix + matrix | Performs matrix addition | { {1,2,3}, {4,5,6} } + { {4,5, {1,2,3} } |
| - (matrix subtraction) | matrix - matrix | Performs matrix subtraction | { {1,2,3}, {4,5,6} } - { {4,5,6 {1,2,3} } |

| Function | Syntax | Purpose | Example |
|---|---|---|---|
| * (scalar multiplication) | numeric * matrix | Performs scalar multiplication | 2 * { {4,5,6}, {1,2,3} } |
| * (matrix multiplication) | matrix * matrix | Performs matrix multiplication | { {1,2,3}, {4,5,6} } * { {1,2}, {3,4}, {5,6} } |
| / (scalar division) | matrix / numeric | Performs scalar division | { {1,2,3}, {4,5,6} } / 2 |
| transpose | transpose(matrix) | Returns the transpose of the matrix | transpose( { {1,2,3}, {4,5,6} |
| determinant | det(matrix) | Returns the determinant of the matrix as a double | det( { {1,2}, {3,4} } ) |
| inverse | inverse(matrix) | Returns the inverse of a square, invertible matrix | inverse( { {1,2}, {3,4} } ) |
| trace | matrix_trace(matrix) | Returns the trace of a square matrix as a double | matrix_trace( { {1,2,3}, {4,5,6}, {7,8,9} } ) |
| vector sum | vector_sum(matrix) | Returns the sum of elements in a one-dimensional matrix/vector | vector_sum( _R3 )<br>vector_sum( _C3 ) |
| vector min | vector_min(matrix) | Returns the minimum of elements in a one-dimensional matrix/vector | vector_min( _R3 )<br>vector_min( _C3 ) |
| vector max | vector_max(matrix) | Returns the maximum of elements in a one-dimensional matrix/vector | vector_max( _R3 )<br>vector_max( _C3 ) |
| vector argmin | vector_argmin(matrix) | Returns the 1-based position (index) of the minimum element in a one-dimensional matrix or vector (row or column vector). The first | vector_argmin(_R0) |

| Function | Syntax | Purpose | Example |
|---|---|---|---|
| | | element has index 1. | |
| vector argmax | vector_argmax(matrix) | Returns the 1-based position (index) of the maximum element of a one-dimensional matrix or vector. The first element has index 1. | vector_argmax(_C0) |
| softmax | softmax(matrix) | Returns the softmax of a one-dimensional matrix or vector. | softmax(_R1) |
| cross entropy loss | cross_entropy_loss(matrix, matrix) | Returns the cross entropy loss of two one-dimensional matrices or vectors. | cross_entropy_loss( _R0.8, _C0<br>cross_entropy_loss( _C0.8, _R0<br>cross_entropy_loss( _R0.8, _R0<br>cross_entropy_loss( _C0.8, _C0 |
| log loss | log_loss(matrix, matrix) | Returns the log loss of two one-dimensional matrices or vectors. | log_loss( _R0.8, _C0 )<br>log_loss( _C0.8, _R0 )<br>log_loss( _R0.8, _R0 )<br>log_loss( _C0.8, _C0 ) |
| logits loss | logits_loss(matrix, matrix) | Returns the logits loss of two one-dimensional matrices or vectors. | logits_loss( _R0.8, _C0 )<br>logits_loss( _C0.8, _R0 )<br>logits_loss( _R0.8, _R0 )<br>logits_loss( _C0.8, _C0 ) |
| hinge loss | hinge_loss(matrix, matrix) | Returns the hinge loss of two one-dimensional matrices or vectors. | hinge_loss( _R0.8, _C0 )<br>hinge_loss( _C0.8, _R0 )<br>hinge_loss( _R0.8, _R0 )<br>hinge_loss( _C0.8, _C0 ) |
| dot product | dot(matrix, matrix) | Returns the dot product of two one-dimensional matrices/vectors | dot( _R3, _C3 )<br>dot( _C3, _R3 )<br>dot( _R3, _R3 )<br>dot( _C3, _C3 ) |
| magnitude | abs(matrix) | Returns the magnitude of one- | abs( _R3 )<br>abs( _C3 ) |

| Function | Syntax | Purpose | Example |
|---|---|---|---|
| | | dimensional matrix/vector | |
| LUPQ decomp | LUPQ_decomp(matrix) | Returns LUPQ decomposition of a square matrix A as a tuple of 4 matrices where PAQ = LU | |
| LUP decomp | LUP_decomp(matrix) | Returns LUP decomposition of a square matrix as a tuple of 3 matrices | |
| QR decomp | qrdecomp(matrix) | Returns QR decomposition of a matrix as a tuple of 2 matrices | |
| SVD decomp | SVD_decomp(matrix) | Returns SVD decomposition of a matrix as a tuple of 3 matrices | |
| eigenvalues/vectors | eigen(matrix) | Returns eigenvalues and eigenvalues of a square matrix as a vector of pairs | |
| identity matrix | identity_matrix(unsigned int) | Returns an identity matrix of the specified dimension | identity_matrix(3) |
| NULL matrix | null_matrix(unsigned int, unsigned int) | Returns a NULL matrix of the specified (row, col) dimensions | null_matrix(2, 3) |
| zero matrix | zero_matrix(unsigned int, unsigned int) | Returns a zero matrix of the specified (row, col) dimensions | zero_matrix(2, 3) |
| matrix dimension | matrix_dim(matrix) | Returns the dimensions of the specified matrix as a tuple of (row, col) integers. When the input matrix is NULL, the | matrix_dim(_R{1, 2, 3}) |

| Function | Syntax | Purpose | Example |
| --- | --- | --- | --- |
| | | function returns NULL. | |
| Frobenius norm | frobenius(matrix) | Returns the Frobenius norm of a matrix. This norm is the matrix norm of an `M`` x ``N` matrix defined as the square root of the sum of the absolute squares of its elements. \|a\|^2 is the same as a^2, where a is a real number. | frobenius(matrix_from_text('{- {8,6}}')) |

# Matrix Operators

| Operator | Syntax | Purpose |
| --- | --- | --- |
| < | matrix < matrix | Less than comparison |
| > | matrix > matrix | Greater than comparison |
| <= | matrix <= matrix | Less than or equal to comparison |
| >= | matrix >= matrix | Greater than or equal to comparison |
| = | matrix = matrix | Equal to comparison |
| <> | matrix <> matrix | Not equal to comparison |
| [,] | matrix[rowIndex,colIndex] | Access the matrix at the specified row and column. 1-Indexed. Accessing a NULL matrix or using a NULL index returns NULL. Access out of bounds returns a NULL. |
| [:,:] | matrix[r1:c1,r2:c2] | Slice the matrix at the specified row range and column range.<br>* The index starts at `1`.<br>* Slicing a NULL matrix or using a NULL index returns NULL.<br>* Start indices omitted or below `1` become `1`. End indices omitted or above the number of rows/columns become the number of rows/columns. Example — `matrix_10X10[:10,-1:20]` is equivalent to |

| Operator | Syntax | Purpose |
| --- | --- | --- |
| | | `matrix[1:10,1:10]` .<br>* Ranges completely out of bounds throw an `INVALID_ARGUMENT` error.<br>* Sequential slices like `matrix[1:1,1:1][1:1,1:1]` throw an error.<br>* Slices cannot be combined with access. `matrix[1,1:10]` is not allowed, but `matrix_10X10[1:1,1:10]` is.<br>* Trying to slice with non-constant indexes throws an error. |

## Operator Examples

| Operator | SQL Predicate | Result |
| --- | --- | --- |
| `<` | `{ {1,2,3}, {4,5,6} } < { {4,5,6}, {1,2,3} }` | true |
| | `{ {1,2,3}, {4,5,6} } < { {1,2,2}, {1,2,3} }` | false |
| | `{ {1,2,3}, {4,5,6} } < { {1,2,3}, {4,5,6} }` | false |
| `>` | `{ {4,5,6}, {4,5,6} } > { {1,2,3}, {7,8,9} }` | true |
| | `{ {1,2,3}, {4,5,6} } > { {4,5,6}, {1,2,3} }` | false |
| | `{ {1,2,3}, {4,5,6} } > { {1,2,3}, {4,5,6} }` | false |
| `<=` | `{ {1,2,3}, {4,5,6} } <= { {4,5,6}, {1,2,3} }` | true |
| | `{ {1,2,3}, {4,5,6} } <= { {1,2,2}, {1,2,3} }` | false |
| | `{ {1,2,3}, {4,5,6} } <= { {1,2,3}, {4,5,6} }` | true |
| `>=` | `{ {4,5,6}, {4,5,6} } >= { {1,2,3}, {7,8,9} }` | true |
| | `{ {1,2,3}, {4,5,6} } >= { {1,5,6}, {1,2,3} }` | false |
| | `{ {1,2,3}, {4,5,6} } >= { {1,2,3}, {4,5,6} }` | true |
| `=` | `{ {1,2,3}, {4,5,6} } = { {1,2,3}, {4,5,6} }` | true |
| | `{ {1,2,3}, {4,5,6} } = { {1,2,4}, {4,5,6} }` | false |
| `<>` | `{ {1,2,3}, {4,5,6} } <> { {1,2,3}, {4,5,6} }` | false |
| | `{ {1,2,3}, {4,5,6} } <> { {1,2,4}, {4,5,6} }` | true |
| `matrix_access_operator` | `{ {1,2,3}, {4,5,6} }[1,2]` | 2.0 |
| | `{ {1,2,3}, {4,5,6} }[NULL,2]` | NULL |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Operator | SQL Predicate | Result |
| --- | --- | --- |
| `matrix_slice_operator` | `{ {1,2,3}, {4,5,6} }[1:,2:3]` | { {2.0,3.0}, {5.0,6.0} } |
| | `{ {1,2,3}, {4,5,6} }[1:NULL,2:3]` | NULL |

# Network Type Functions

Reference for Ocient SQL network type functions that parse, inspect, and operate on IP address, CIDR block, and MAC address values for network analytics.

The Ocient® System supports these functions for `IP` and `IPV4` data types.

## IP

Casts the `IPV4` data type to the `IP` data type. The returned value is the IPv6-mapped IPv4 address.

### Syntax

SQL

```
IP(ipv4_col)
```

| Argument | Data Type | Description |
|---|---|---|
| `ipv4_col` | `CHAR` or `IPV4` | IP address in the `IPV4` data type to cast. |

### Example

Cast the IPv4 address `128.1.2.3` to the IPv6-mapped IPv4 address.

SQL

```
SELECT IP(IPV4('128.1.2.3'));
```

*Output*

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

Text

```
ip(ipv4(('128.1.2.3')))
-----------------------------------------------
128.1.2.3

Fetched 1 row
```

# IPV4

Returns the IPv4 portion of the IPv6 address.

You can only cast the IP data type to IPv4 if the IPv6 value has an IPv4 semantic equivalent. The database can convert these IPv6 address formats to IPv4:

- IPv4-compatible IPv6 `::x.x.x.x`
- IPv6-mapped IPv4 `::ffff:x.x.x.x`
- NAT64-prefixed `64:ff9b::x.x.x.x`

### Syntax

SQL

```
IPV4(ip_col)
```

| Argument | Data Type | Description |
|---|---|---|
| `ip_col` | `IP` | IPv6-mapped IP address in the `IP` data type to cast.<br><br>If the IPv6 address is not IPv4-compatible, IPv6-mapped, or NAT64-prefixed, the cast returns an `INVALID DATA TYPE CONVERSION` error. |

### Example

Cast the IPv6-mapped IP address `::ffff:128.1.2.3` to the `IPV4` data type. Return the IPv4 portion of the address.

SQL

```
SELECT IPV4(IP('::ffff:128.1.2.3'));
```

*Output*

Text

```
ipv4(ip(('::ffff:128.1.2.3')))
------------------------------
128.1.2.3

Fetched 1 row
```

# IS_IPV4

The `IS_IPV4` function tests whether the database can convert the `IP` value to the `IPV4` data type. The database can convert these IPv6 address formats to IPv4:

- IPv4-compatible IPv6 `::x.x.x.x`
- IPv6-mapped IPv4 `::ffff:x.x.x.x`
- NAT64-prefixed `64:ff9b::x.x.x.x`

The function returns a Boolean value ( `true` or `false` ) that indicates whether the conversion works from the specified IP address to the IPv4 address.

### Syntax

SQL

```
IS_IPV4(ip_col)
```

| Argument | Data Type | Description |
|---|---|---|
| `ip_col` | `IP` | Specified IP address for conversion to an IPv4 address. |

### Example

Determine whether the `::fffe:128.1.2.3` string is a valid IPv4 address. Use the `IP` function to cast the string as an IP address.

```sql
SELECT IS_IPV4(IP('::fffe:128.1.2.3'));
```

*Output*

```text
is_ipv4_convertible(ip(('::fffe:128.1.2.3')))
----------------------------------------------
false

Fetched 1 row
```

# SUBNET

The `SUBNET` function computes the prefix from an `IP` or `IPV4` value and the size of the prefix. The function returns a value of the same type as the `ip_col` argument.

### Syntax

```sql
SUBNET(ip_col, prefix_size)
```

| Argument | Data Type | Description |
|---|---|---|
| `ip_col` | `IP` or `IPV4` | The IP address for the prefix calculation. |
| `prefix_size` | Integer | The size of the subnet network prefix. For `IPV4` addresses, the size must be in the range [0, 32], and for `IP` addresses, the size must be in the range [0, 128]. If the prefix exceeds these range values, the function returns an `INVALID ARGUMENT` error. |

### Example

Calculate the prefix for the NAT64-prefixed IP address `64:ff9b::128.2.3.4` with prefix size `98`. Use the `IP` function to cast the string as an IP address.

SQL

```
SELECT SUBNET(IP('64:ff9b::128.2.3.4'), 98);
```

*Output*

Text

```
subnet(ip(('64:ff9b::128.2.3.4')), (98))
-----------------------------------------
64:ff9b:0:0:0:0:8000:0

Fetched 1 row
```

# Scalar Data Conversion Functions

Reference for Ocient SQL scalar conversion functions such as CAST, CONVERT, TO_CHAR, and TO_NUMBER to transform values between supported data types.

These functions convert one data type to another.

## Scalar Data Conversion Functions

| Function | Syntax | Purpose |
|---|---|---|
| BYTE | BYTE(numeric value) | Casts the argument to a value of type byte |
| | BYTE(character value) | Parses the string as a byte value |
| SMALLINT | SMALLINT(numeric value) | Casts the argument to a value of type smallint |
| | SMALLINT(character value) | Parses the string as a `smallint` value |
| INTEGER | INT(numeric value) or INTEGER(numeric value) | Casts the argument to a value of type integer |
| | INT(character value) or INTEGER(character value) | Parses the string as an integer value |
| BIGINT | BIGINT(numeric value) | Casts the argument to a value of type bigint |
| | BIGINT(character value) | Parses the string as a `bigint` value |
| | BIGINT(time value) | Creates a `bigint` with the number of milliseconds represented by the time argument |
| | BIGINT(timestamp value) | Creates a `bigint` with the number of milliseconds after the Unix® epoch corresponding to the timestamp argument |
| FLOAT | FLOAT(numeric value) | Casts the argument to a value of type float |
| | FLOAT(character value) | Parses the string as a float value |
| DOUBLE | DOUBLE(numeric value) | Casts the argument to a value of type double |
| | DOUBLE(character value) | Parses the string as a double value |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function | Syntax | Purpose |
|---|---|---|
| DECIMAL | DECIMAL(numeric value) | Casts the argument to a value of type decimal |
| | DECIMAL(character value) | Parses the string and creates a decimal value |
| | DECIMAL(numeric value, integer value, integer value) | Casts the first argument to a decimal value with precision of the second argument and scale of the third argument |
| | DECIMAL(character value, integer value, integer value) | Parses the first argument to a decimal value with precision of the second argument and scale of the third argument |
| CHAR \| STR | CHAR(numeric value) | Creates a string version of the numeric value |
| | CHAR(character value) | None |
| | CHAR(timestamp) | Creates a string representation of the timestamp |
| | CHAR(date) | Creates a string representation of the date |
| | CHAR(time) | Creates a string representation of the time |
| | CHAR(boolean) | Creates a string representation of the Boolean value |
| | CHAR(binary) | Creates a hexadecimal string representation of the binary value |
| | CHAR(ip) | Creates a string representation of the IPV4 or IPV6 value |
| | CHAR(ipv4) | Creates a string representation of the IPV4 value |
| | CHAR(hash) | Creates a string representation of the fixed-binary hash value |
| | CHAR(point) | Creates a string representation of the point value |
| | CHAR(uuid) | Creates a string representation of the Universally Unique IDentifier (UUID) |
| BINARY | BINARY(character value) | Parses a hexadecimal string (such as `0x54ab`) to create a binary value. Letters can be in either case. |
| | BINARY(binary) | None |

| Function | Syntax | Purpose |
|---|---|---|
| | BINARY(hash) | Converts the fixed-length binary value (hash) to a variable-length binary value |
| BOOLEAN | BOOLEAN(character value) | Parses a string to create a Boolean value.<br><br>The function converts any of these string values to `TRUE` : `true` , `t` , `yes` , `y` , `on` , `1` .<br><br>The function converts any of these string values to `FALSE` : `false` , `f` , `no` , `n` , `off` , `0` .<br><br>The string parsing is case-insensitive. Any unsupported string values raise an error. |
| | BOOLEAN(numeric value) | Parses a numeric value to create a Boolean value.<br><br>The function converts any non-zero value to `TRUE` .<br><br>The function converts `0` to `FALSE` . |
| | BOOLEAN(boolean) | None |
| DATE | DATE(character value) | Parses a string in the form ‘YYYY-MM-DD’ to create a date. Extra characters are ignored. |
| | DATE(date) | None |
| | DATE(timestamp) | Truncates a timestamp to be a date value |
| HASH | HASH(char, length) | Creates a fixed-length binary value, with length <length>, from a string, i.e., 0x1234abcd. Zero extended if the string does not have enough bytes, truncated if it has too many. |
| | HASH(binary, length) | Creates a fixed-length binary value, with length <length>, from a variable-length binary value. Zero extended if the string does not have enough bytes, truncated if it has too many. |
| IP | IP(character value) | Creates a value of type IPV4 or IPV6 from a string |
| IPV4 | IPV4(character value) | Parses a string containing an IP address and creates a value of type IPV4 |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function | Syntax | Purpose |
|---|---|---|
| | IPV4(ipv4) | no-op |
| TIME | TIME(character value) | Parses the string to create a time value. The string must be in the form `'HH:MM[.SSSSSSSSS]'` |
| | TIME(bigint) | Creates a time value representing a certain number of milliseconds after midnight |
| | TIME(time) | None |
| | TIME(timestamp) | Makes a time value from the time component of a timestamp |
| TIMESTAMP | TIMESTAMP(character value) | Parses a string and makes a timestamp value. The string must be in the format `'YYYY-MM-DD[ HH:MM][.SSSSSSSSS]'`. |
| | TIMESTAMP(date) | Makes a timestamp from the date by setting the time component to `00:00:00.0` |
| | TIMESTAMP(timestamp) | None |
| | TIMESTAMP(bigint value) | Creates a timestamp from a `bigint` representing the number of milliseconds after the Unix epoch (1/1/1970). |
| UUID | UUID(character value) | Parses the string and makes a UUID value. The string must be a valid UUID. |
| | UUID(uuid) | None |
| WEEKS | WEEKS(integral value) | Converts an integral value to an interval value of type weeks for date calculations. |
| | Weeks(weeks) | None |
| DAYS | DAYS(integral value) | Converts an integral value to an interval value of type days for date calculations. |
| | DAYS(days) | None |
| | DAYS(weeks) | Converts an interval value of type weeks to an interval value of type days representing the same time span. |
| MONTHS | MONTHS(integral value) | Converts an integral value to an interval value of type months for date calculations. |
| | MONTHS(months) | None |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function | Syntax | Purpose |
|---|---|---|
| | MONTHS(years) | Converts an interval value of type years to an interval value of type months representing the same time span |
| YEARS | YEARS(integral value) | Converts an integral value to an interval value of type years |
| | YEARS(years) | None |
| HOURS | HOURS(integral value) | Converts an integral value to an interval value of type hours |
| | HOURS(hours) | None |
| | HOURS(days) | Converts an interval value of type days to an interval value of type hours representing the same time span. |
| | HOURS(weeks) | Converts an interval value of type weeks to an interval value of type hours representing the same time span. |
| MINUTES | MINUTES(integral value) | Converts an integral value to an interval value of type minutes |
| | MINUTES(minutes) | None |
| | MINUTES(hours) | Converts an interval value of type hours to an interval value of type minutes representing the same time span |
| | MINUTES(days) | Converts an interval value of type days to an interval value of type minutes representing the same time span |
| | MINUTES(weeks) | Converts an interval value of type weeks to an interval value of type minutes representing the same time span |
| SECONDS | SECONDS(integral value) | Converts an integral value to an interval value of type seconds |
| | SECONDS(seconds) | None |
| | SECONDS(minutes) | Converts an interval value of type minutes to an interval value of type seconds representing the same time span |
| | SECONDS(hours) | Converts an interval value of type hours to an interval value of type seconds representing the same time span |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function | Syntax | Purpose |
|---|---|---|
| | SECONDS(days) | Converts an interval value of type days to an interval value of type seconds representing the same time span |
| | SECONDS(weeks) | Converts an interval value of type weeks to an interval value of type seconds representing the same time span |
| MILLISECONDS | MILLISECONDS(integral value) | Converts an integral value to an interval value of type milliseconds |
| | MILLISECONDS(milliseconds) | None |
| | MILLISECONDS(seconds) | Converts an interval value of type seconds to an interval value of type milliseconds, representing the same time span |
| | MILLISECONDS(minutes) | Converts an interval value of type minutes to an interval value of type milliseconds representing the same time span |
| | MILLISECONDS(hours) | Converts an interval value of type hours to an interval value of type milliseconds representing the same time span |
| | MILLISECONDS(days) | Converts an interval value of type days to an interval value of type milliseconds representing the same time span |
| | MILLISECONDS(weeks) | Converts an interval value of type weeks to an interval value of type milliseconds representing the same time span |
| MICROSECONDS | MICROSECONDS(integral value) | Converts an integral value to an interval value of type microseconds |
| | MICROSECONDS(milliseconds) | Converts an interval value of type milliseconds to an interval value of type microseconds representing the same time span |
| | MICROSECONDS(seconds) | Converts an interval value of type seconds to an interval value of type microseconds representing the same time span |
| | MICROSECONDS(minutes) | Converts an interval value of type minutes to an interval value of type microseconds representing the same time span |
| | MICROSECONDS(hours) | Converts an interval value of type hours to an interval value of type microseconds representing the same time span |

© 2026 Ocient, Inc

| Function | Syntax | Purpose |
|---|---|---|
| | MICROSECONDS(days) | Converts an interval value of type days to an interval value of type microseconds representing the same time span |
| | MICROSECONDS(weeks) | Converts an interval value of type weeks to an interval value of type microseconds representing the same time span |
| | MICROSECONDS(microseconds) | None |
| NANOSECONDS | NANOSECONDS(integral value) | Converts an integral value to an interval value of type nanoseconds |
| | NANOSECONDS(microseconds) | Converts an interval value of type microseconds to an interval value of type nanoseconds representing the same time span |
| | NANOSECONDS(milliseconds) | Converts an interval value of type milliseconds to an interval value of type nanoseconds representing the same time span |
| | NANOSECONDS(seconds) | Converts an interval value of type seconds to an interval value of type nanoseconds representing the same time span |
| | NANOSECONDS(minutes) | Converts an interval value of type minutes to an interval value of type nanoseconds representing the same time span |
| | NANOSECONDS(hours) | Converts an interval value of type hours to an interval value of type nanoseconds representing the same time span |
| | NANOSECONDS(days) | Converts an interval value of type days to an interval value of type nanoseconds representing the same time span |
| | NANOSECONDS(weeks) | Converts an interval value of type weeks to an interval value of type nanoseconds representing the same time span |
| | NANOSECONDS(nanoseconds) | None |

# Implicit Conversions

In certain situations, Ocient® SQL can automatically convert expressions to a specific data type without an explicit SQL statement.

## Cast from Strings

You can cast string literals to any other data type by placing the name of the data type before the string literal.

### Examples

#### Cast a Double

Cast the value `1.5` from a string to a floating-point value.

```
SQL
SELECT DOUBLE '1.5';
```

*Output: * `1.5`

#### Cast an Array

Cast the array `INT[0,1,2,3]` from a string to an array of integers.

```
SQL
SELECT INT[] 'INT[0,1,2,3]';
```

*Output: * `['0','1','2','3']`

#### Cast a Point Value

Cast the point value `POINT(0 0)` to the geospatial data type `POINT`. In this case, the cast keyword is `ST_POINT`, and the data type is `POINT`.

```
SQL
SELECT ST_POINT 'POINT(0 0)';
```

*Output: * `POINT(0.0 0.0)`

## Cast from Date and Time Strings

You can cast date and time values to their interval value with the `INTERVAL` keyword.

**Retrieve Interval Values from Various Date and Time Strings**

Retrieve the interval value `5` from the `'5 DAYS'` string.

```
SQL

SELECT INTERVAL '5 DAYS';
```

*Output: * `5`

Retrieve the interval value `2` from the `'2 WEEKS'` string.

```
SQL

SELECT INTERVAL '2 WEEKS';
```

*Output: * `2`

Retrieve the interval value `10` from the `'10 SECONDS'` string.

```
SQL

SELECT INTERVAL '10 SECONDS';
```

*Output:* `10`

# CAST Functions

These SQL statements allow casting an expression to any other data type.

## CAST

Transforms an expression to any other data type.

This function operates similarly to the **:: Operator**.

**Syntax**

```sql
CAST[!] expr [AS] data_type
```

| Argument | Data Type | Description |
|---|---|---|
| `expr` | Any | A column or value to transform to another data type. |
| `data_type` | String | Any of the Ocient-supported data types. For a full list, see **Data Types**. |

> As shown in the syntax examples, `CAST` can support the optional `!` operator.
>
> The `!` operator returns a NULL value if the operation cannot cast to the specified data type. This behavior prevents situations where the system would normally raise an error.

## Examples

### Cast an Integer to Varchar

Transform the value `2` as a `VARCHAR` string.

```sql
SELECT CAST(2 AS VARCHAR);
```

*Output:* `'2'`

### Cast a Varchar to Date

Transform the `'2020-02-02'` string to the `DATE` data type.

```sql
SELECT CAST('2020-02-02' AS DATE);
```

*Output: * `'2020-02-02'`

### Cast an Incompatible Type with the `!` Operator

Transform the `'a'` string to an integer, or `INT` data type, using the `!` operator.

```
SQL

SELECT CAST!('a' AS INT);
```

*Output:* `NULL`

This operation generates NULL because the database cannot transform this value to an integer. Without adding this operator, the statement raises an error because the database cannot transform the input expression to a numeric type.

## `::` Operator

Transforms an expression to any other data type.

This function operates similarly to the **CAST** function.

### `::` Syntax

```
SQL

expr ::[!] data_type
```

| Argument | Data Type | Description |
|---|---|---|
| `expr` | Any | A column or value to transform to another data type. |
| `data_type` | String | Any of the Ocient-supported data types. For a full list, see **Data Types**. |

> As shown in the syntax examples, `::` can support the optional `!` operator.
>
> The `!` operator returns a NULL value if the operation cannot cast to the specified data type. This behavior prevents situations where the system would normally raise an error.

### Examples

### Cast an Integer to Float

Transform the `'2'` string to a floating-point number.

```sql
SELECT '2' :: FLOAT;
```

*Output:* `2.0`

**Cast to an Incompatible Type with the `!` Operator**

Transform the `'a'` string to an integer, or `INT` data type, using the `!` operator.

```sql
SELECT 'a' ::! INT;
```

*Output:* `NULL`

This operation generates NULL because the database cannot transform this value to an integer. Without adding this operator, the statement raises an error because the database cannot transform the input expression to a numeric type.

## Map Functions

A map is a set of key-value pairs that the Ocient System stores as two parallel arrays: one array of keys and one array of values. The key at each position in the key array corresponds to the value at the same position in the value array. You can store a map in a single column with the data type `TUPLE<<key_type[], value_type[]>>`, where the first tuple element is the key array and the second tuple element is the value array. The map functionality is similar to a Python® dictionary `dict` or a hash table.

The map functions insert, retrieve, and remove key-value pairs in a map. Each map function accepts a map as a single `TUPLE` type argument or as two separate `ARRAY` type arguments.

These rules apply to all map functions:

- The key array and the value array can use different element data types, and each array supports scalar element data types such as `INT`, `CHAR`, `DATE`, `TIMESTAMP`,

`DECIMAL`, `UUID`, and `POINT`.

- The keys in a map must be unique. If the key array contains duplicate keys, the function returns an error.
- A NULL key is a valid map key. A map can contain at most one entry with a NULL key.
- If the map argument is NULL, the function returns NULL.

## MAP_DELETE

Removes the entry for the specified key from a map. If the key is not present in the map, the function returns the map unchanged. If you specify a NULL key, the function removes the entry with the NULL key. The function returns the resulting map as a `TUPLE` type containing the key and value arrays.

### Syntaxes

#### Remove a Key from a Map Tuple

Removes the entry for the specified key from a map that you specify as a tuple.

SQL

```
MAP_DELETE(map, key)
```

| Argument | Data Type | Description |
|---|---|---|
| `map` | TUPLE | A map as a `TUPLE` type containing two parallel arrays with the data type `TUPLE<<key_type[], value_type[]>>`. The first tuple element is the key array, and the second tuple element is the value array. |
| `key` | Element data type of the key array | The key to remove from the map. |

#### Remove a Key from Separate Key and Value Arrays

Removes the entry for the specified key from a map that you specify as separate key and value arrays.

```sql
MAP_DELETE(keys_array, values_array, key)
```

| Argument | Data Type | Description |
|---|---|---|
| `keys_array` | ARRAY | The array that contains the keys of the map. |
| `values_array` | ARRAY | The array that contains the values of the map. The value at each position in this array corresponds to the key at the same position in the `keys_array` argument. |
| `key` | Element data type of the key array | The key to remove from the map. |

### Examples

#### Remove a Key from a Map Tuple

Remove the key `1` and its value from a map that contains two entries.

```sql
SELECT MAP_DELETE(TUPLE<<INT[], INT[]>>(INT[](1, 2), INT[](10, 20)), 1);
```

*Output:* `TUPLE<<INT[], INT[]>>(INT[](2), INT[](20))`

#### Remove a Key from Separate Key and Value Arrays

Remove the key `'bob'` and its value from a map with character keys and integer values.

```sql
SELECT MAP_DELETE(CHAR[]('alice', 'bob'), INT[](10, 20), 'bob');
```

*Output:* `TUPLE<<CHAR[], INT[]>>(CHAR[]('alice'), INT[](10))`

## MAP_GET

Returns the value for the specified key in a map. If the key is not present in the map, the function returns NULL. If you specify a NULL key, the function returns the value for the entry with the NULL key. The function also returns NULL when the stored value for the key is NULL, so a NULL result can mean either that the key is not present or that its value is NULL.

### Syntaxes

#### Retrieve a Value from a Map Tuple

Returns the value for the specified key from a map that you specify as a tuple.

```
SQL

MAP_GET(map, key)
```

| Argument | Data Type | Description |
|---|---|---|
| `map` | TUPLE | A map as a `TUPLE` type containing two parallel arrays with the data type `TUPLE<<key_type[], value_type[]>>`. The first tuple element is the key array, and the second tuple element is the value array. |
| `key` | Element data type of the key array | The key to find in the map. |

#### Retrieve a Value from Separate Key and Value Arrays

Returns the value for the specified key from a map that you specify as separate key and value arrays.

```
SQL

MAP_GET(keys_array, values_array, key)
```

| Argument | Data Type | Description |
|---|---|---|
| `keys_array` | ARRAY | The array that contains the keys of the map. |

| Argument | Data Type | Description |
| --- | --- | --- |
| `values_array` | ARRAY | The array that contains the values of the map. The value at each position in this array corresponds to the key at the same position in the `keys_array` argument. |
| `key` | Element data type of the key array | The key to find in the map. |

### Examples

#### Retrieve a Value from a Map Tuple

Retrieve the value for the key `'bob'` from a map with character keys and integer values.

SQL

```
SELECT MAP_GET(TUPLE<<CHAR[], INT[]>>(CHAR[]('alice', 'bob'), INT[](10, 20)), 'bob'
```

*Output:* `20`

#### Retrieve a Value from Separate Key and Value Arrays

Retrieve the value for the key `3`. The key is not present in the map, so the function returns NULL.

SQL

```
SELECT MAP_GET(INT[](1, 2), CHAR[]('x', 'y'), 3);
```

*Output:* `NULL`

## MAP_PUT

Inserts a key-value pair into a map. If the key is already present in the map, the function replaces its value and keeps its position in the key array. The function returns the resulting map as a `TUPLE` type containing the key and value arrays.

The data type of the `key` argument must match the element data type of the key array, and the data type of the `value` argument must match the element data type of the value array. Otherwise, the function returns an error.

You can insert a NULL key or a NULL value. If the map already contains an entry with a NULL key, the function replaces its value.

### Syntaxes

### Insert a Key-Value Pair into a Map Tuple

Inserts a key-value pair into a map that you specify as a tuple.

```
SQL

MAP_PUT(map, key, value)
```

| Argument | Data Type | Description |
|---|---|---|
| `map` | TUPLE | A map as a `TUPLE` type containing two parallel arrays with the data type `TUPLE<<key_type[], value_type[]>>`. The first tuple element is the key array, and the second tuple element is the value array. |
| `key` | Element data type of the key array | The key to insert into the map. |
| `value` | Element data type of the value array | The value to associate with the key. |

### Insert a Key-Value Pair into Separate Key and Value Arrays

Inserts a key-value pair into a map that you specify as separate key and value arrays.

```
SQL

MAP_PUT(keys_array, values_array, key, value)
```

| Argument | Data Type | Description |
|---|---|---|
| `keys_array` | ARRAY | The array that contains the keys of the map. |
| `values_array` | ARRAY | The array that contains the values of the map. The value at each position in this array corresponds to the key at the same position in the `keys_array` argument. |

| Argument | Data Type | Description |
| --- | --- | --- |
| `key` | Element data type of the key array | The key to insert into the map. |
| `value` | Element data type of the value array | The value to associate with the key. |

### Examples

#### Insert a New Key into a Map Tuple

Insert the key `2` with the value `20` into a map that contains one entry.

SQL

```
SELECT MAP_PUT(TUPLE<<INT[], INT[]>>(INT[](1), INT[](10)), 2, 20);
```

*Output:* `TUPLE<<INT[], INT[]>>(INT[](1, 2), INT[](10, 20))`

#### Update an Existing Key in Separate Key and Value Arrays

Insert the key `1` with the value `30`. The key is already present in the map, so the function replaces its value while keeping its position.

SQL

```
SELECT MAP_PUT(INT[](1, 2), INT[](10, 20), 1, 30);
```

*Output:* `TUPLE<<INT[], INT[]>>(INT[](1, 2), INT[](30, 20))`

# Time Zone Functions

Reference for Ocient SQL time zone functions that convert, format, and manipulate timestamp values across regions and IANA time zone database identifiers.

⚠ The Ocient® cluster system administrator is responsible for keeping the OS time zone database (e.g., on Ubuntu®, `tzdata`) up to date. Outdated time zone database files might cause unexpected results due to IANA rule updates around name changes, DST observance, and UTC offsets for time zones.

ⓘ The `TIMESTAMP` data type has no associated time zone value. The database administrator tracks the associated time zone with a `TIMESTAMP` column, whether through an associated `time_zone` `VARCHAR` column or other documentation. Ocient recommends storing all `TIMESTAMP` data types in the UTC time zone to avoid ambiguity and using these functions to convert to arbitrary time zones. You can still store `TIMESTAMP` data types associated with an arbitrary time zone and use these functions to convert to UTC and from UTC to another time zone.

## CONVERT_UTC_TIMESTAMP_TO_LOCAL

The function converts a timestamp from the UTC time zone to a specified local time zone.

This function can take the `timezone` argument as a `VARCHAR` literal, or the argument can be a column. When the argument is a literal, you can arbitrarily capitalize it. When the argument is a column, the values in the column must be capitalized according to the canonical **IANA time zone names,** such as `'America/Chicago'`.

### Syntax

SQL

```
SELECT CONVERT_UTC_TIMESTAMP_TO_LOCAL(timestamp,timezone)
```

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Argument | Data Type | Description |
| --- | --- | --- |
| `timestamp` | `TIMESTAMP` or `VARCHAR` | Timestamp to convert that you specify as a `TIMESTAMP` or `VARCHAR` that you typecast in a timestamp format. |
| `timezone` | `VARCHAR` | `VARCHAR` that contains the full name of the target time zone. |

## Examples

### Convert a Constant Time Zone Value

Convert timestamp `2022-11-06 02:09:00` to the local time in Chicago.

SQL

```
SELECT CONVERT_UTC_TIMESTAMP_TO_LOCAL(Timestamp '2022-11-06 02:09:00','America/Chic
```

*Output*

Text

```
CONVERT_UTC_TIMESTAMP_TO_LOCAL(timestamp(('2022-11-06 02:09:00')), ('America/Chicag
--------------------------------------------------------------------------------
2022-11-05 21:09:00.000000000
```

### Convert a Timestamp Value in a Column

Convert the timestamp in the `ts` column to the local time in Chicago using the `test_timezone` table.

SQL

```
SELECT CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts,'America/Chicago') FROM test_timezone;
```

*Output*

```
Text

CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts, ('America/Chicago'))
-----------------------------------------------------
2023-01-09 17:23:12.173997444
```

## Convert a Timestamp Value and Time Zone Name in Columns

Convert the timestamp in the `ts` column to the local time specified by the `timezone_name` column using the `test_timezone` table.

```
SQL

SELECT CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts,timezone_name) FROM test_timezone;
```

*Output*

```
Text

CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts, timezone_name)
-------------------------------------------------
2023-01-09 17:43:21.193229991
```

## Convert a Timestamp Value Using Other Date and Time Functions

Use the `TO_TIMESTAMP` function to convert a numeric timestamp to the local time in Chicago.

```
SQL

SELECT CONVERT_UTC_TIMESTAMP_TO_LOCAL(TO_TIMESTAMP(1534587890), 'America/Chicago');
```

*Output*

```
Text

CONVERT_UTC_TIMESTAMP_TO_LOCAL(to_timestamp((1534587890)), ('America/Chicago'))
-------------------------------------------
2018-08-18 05:24:50.000000000
```

Use a UTC timestamp from the output of the `CONVERT_LOCAL_TIMESTAMP_TO_UTC` function with Chicago time and convert it back to local time in Chicago.

SQL

```
SELECT CONVERT_UTC_TIMESTAMP_TO_LOCAL(CONVERT_LOCAL_TIMESTAMP_TO_UTC(Timestamp '202
    'America/Chicago');
```

*Output*

Text

```
CONVERT_UTC_TIMESTAMP_TO_LOCAL(CONVERT_LOCAL_TIMESTAMP_TO_UTC(timestamp(('2022-11-C
-------------------------------------------------------------------------------
2022-11-09 01:59:00.000000000
```

Extract the hour portion of the local Chicago time using the output of the `TO_TIMESTAMP` function on a numeric timestamp.

SQL

```
SELECT HOUR(CONVERT_UTC_TIMESTAMP_TO_LOCAL(TO_TIMESTAMP(1534587890), 'America/Chica
```

*Output*

Text

```
hour(CONVERT_UTC_TIMESTAMP_TO_LOCAL(to_timestamp((1534587890)), ('America/Chicago')
-------------------------------------------------------------------------------
5
```

## Convert a Timestamp During Table Creation

Create a table using a `SELECT` statement that converts a timestamp in local Chicago time.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
CREATE TABLE test_timezone_2 (ts timestamp, b int)
    AS (SELECT CONVERT_UTC_TIMESTAMP_TO_LOCAL(Timestamp '2022-11-06 02:09:00', 'Ame
        1 FROM sys.dummy1);

Modified 1 row

SELECT * FROM test_timezone_2;            1
```

*Output*

Text

```
ts_1                                        b_1
-------------------------------------------------------------------------------
2022-11-05 21:09:00.000000000
```

## Convert a Timestamp During an Insert Operation

Insert a timestamp in local Chicago time into the `test_timezone_2` table.

SQL

```
INSERT INTO test_timezone_2 SELECT CONVERT_UTC_TIMESTAMP_TO_LOCAL(Timestamp '2022-1
    1 FROM sys.dummy1;

Modified 1 row
```

## Convert a Timestamp in a Query Filter

Use timestamp, a numeric constant value in local Chicago time, as a filter on the column `ts` in the `test_timezone` table.

SQL

```
SELECT * FROM test_timezone
    WHERE ts=CONVERT_UTC_TIMESTAMP_TO_LOCAL(Timestamp '2022-11-06 14:09:00', 'Ameri
```

*Output*

```
Text

ts                                                  b
-----------------------------------------------------------
2022-11-06 08:09:00.000000000                       1
```

Use timestamp, a runtime value from the table column `ts` in local Chicago time, as a filter on the `test_timezone` table.

```
SQL

SELECT * FROM test_timezone
    WHERE CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts::timestamp, 'America/Chicago')='2022-11
```

*Output*

```
Text

ts                                                  b
-----------------------------------------------------------
2022-11-06 08:09:00.000000000                       1
```

## Convert a Timestamp in the Grouping Part of the Query

Group the query results by a timestamp converted to local time in Chicago.

```
SQL

SELECT CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts::timestamp, 'America/Chicago')
    FROM test_timezone GROUP BY CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts::timestamp, 'Amer
```

*Output*

Text

```
CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts, ('America/Chicago'))
-----------------------------------------------------
2022-11-05 04:09:00.000000000
2022-11-09 02:09:00.000000000
2022-11-04 04:09:00.000000000
2022-11-06 02:09:00.000000000
```

Using a grouping, omit the `2022-11-10 02:09:00` timestamp using the `HAVING` clause.

SQL

```
SELECT CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts::timestamp, 'America/Chicago')
    FROM test_timezone GROUP BY CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts::timestamp, 'Amer
    HAVING CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts::timestamp, 'America/Chicago') != '202
```

*Output*

Text

```
CONVERT_UTC_TIMESTAMP_TO_LOCAL(ts, ('America/Chicago'))
-----------------------------------------------------
2022-11-06 02:09:00.000000000
2022-11-04 04:09:00.000000000
2022-11-05 04:09:00.000000000
```

# CONVERT_LOCAL_TIMESTAMP_TO_UTC

The function converts a timestamp in a specified local time zone to the UTC time zone. In the case of ambiguous timestamps, the database returns the earliest of the two possible times in the UTC time zone. Ambiguous timestamps refer to the times when the DST time zone change happens, and 1 hour can transform to either 1 or +1 and 1 or -1. Ambiguous timestamps can also refer to non-existent times, such as `2023-03-12 02:01:00 'America/New_York'`, which are similarly converted to the earliest possible UTC time, `2023-03-12 07:00:00 'UTC'`, due to the skipping of hour `02:00:00` entirely with DST spring forward.

This function can take the `timezone` argument as a `VARCHAR` literal, or the argument can be a column. When the argument is a literal, you can arbitrarily capitalize it. When the argument is a column, the values in the column must be capitalized according to the canonical IANA time zone names, such as `'America/Chicago'`.

## Syntax

SQL

```
SELECT CONVERT_LOCAL_TIMESTAMP_TO_UTC(timestamp,timezone)
```

| Argument | Data Type | Description |
|---|---|---|
| `timestamp` | `TIMESTAMP` or `VARCHAR` | Timestamp to convert that you specify as a `TIMESTAMP` or `VARCHAR` that you typecast in a timestamp format. |
| `timezone` | `VARCHAR` | `VARCHAR` that contains the full name of the target time zone. |

## Examples

### Convert a Constant Time Zone Value

Convert timestamp `2022-11-06 02:09:00` to Chicago UTC time.

SQL

```
SELECT CONVERT_LOCAL_TIMESTAMP_TO_UTC(Timestamp '2022-11-06 02:09:00','America/Chic
```

*Output*

Text

```
CONVERT_LOCAL_TIMESTAMP_TO_UTC(timestamp(('2022-11-06 02:09:00')), ('America/Chicag
--------------------------------------------------------------------------------
2022-11-06 08:09:00.000000000
```

### Convert a Timestamp Value in a Column

Convert the timestamp in the `ts` column to Chicago UTC time using the `test_timezone` table.

SQL

```
SELECT CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts,'America/Chicago') FROM test_timezone;
```

*Output*

Text

```
CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts, ('America/Chicago'))
------------------------------------------------------
2023-01-09 17:23:12.173997444
```

## Convert a Timestamp Value and Time Zone Name in Columns

Convert the timestamp in the `ts` column to the UTC time specified by the `timezone_name` column using the `test_timezone` table.

SQL

```
SELECT CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts,timezone_name) FROM test_timezone;
```

*Output*

Text

```
CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts, timezone_name)
------------------------------------------------
2023-01-09 17:43:21.193229991
```

## Convert a Timestamp Value Using Other Date and Time Functions

Use the `TO_TIMESTAMP` function to convert a numeric timestamp to the Chicago UTC time.

SQL

```
SELECT CONVERT_LOCAL_TIMESTAMP_TO_UTC(TO_TIMESTAMP(1534587890), 'America/Chicago');
```

© 2026 Ocient, Inc

*Output*

```
Text

CONVERT_LOCAL_TIMESTAMP_TO_UTC(to_timestamp((1534587890)), ('America/Chicago'))
-----------------------------------------------
2018-08-18 15:24:50.000000000
```

Use a local timestamp from the output of the `CONVERT_UTC_TIMESTAMP_TO_LOCAL` function with Chicago time and convert it back to UTC time.

```
SQL

SELECT CONVERT_LOCAL_TIMESTAMP_TO_UTC(TO_TIMESTAMP(CONVERT_UTC_TIMESTAMP_TO_LOCAL(T
    'America/Chicago');
```

*Output*

```
Text

CONVERT_LOCAL_TIMESTAMP_TO_UTC(CONVERT_UTC_TIMESTAMP_TO_LOCAL(timestamp(('2022-11-C
-------------------------------------------------------------------------------
2022-11-06 01:59:00.000000000
```

## Convert a Timestamp During Table Creation

Create a table using a `SELECT` statement that converts a timestamp in Chicago UTC time.

```
SQL

CREATE TABLE test_timezone (ts timestamp, b int)
    AS (SELECT CONVERT_LOCAL_TIMESTAMP_TO_UTC(Timestamp '2022-11-09 02:09:00', 'Ame
    1 FROM sys.dummy1);

Modified 1 row

SELECT * FROM test_timezone;
```

*Output*

Text

```
ts                                              b
-------------------------------------------------
2022-11-09 08:09:00.000000000                   1
```

### Convert a Timestamp During an Insert Operation

Insert a timestamp in Chicago UTC time into the `test_timezone` table.

SQL

```
INSERT INTO test_timezone SELECT CONVERT_LOCAL_TIMESTAMP_TO_UTC(Timestamp '2022-11-
    1 from sys.dummy1;

Modified 1 row
```

### Convert a Timestamp in a Query Filter

Use a UTC timestamp in Chicago as a numeric constant value to filter on the column `ts` in the `test_timezone` table.

SQL

```
SELECT * FROM test_timezone
    WHERE ts=CONVERT_LOCAL_TIMESTAMP_TO_UTC(Timestamp '2022-11-06 02:09:00', 'Ameri
```

*Output*

Text

```
ts                                              b
-------------------------------------------------------
2022-11-06 08:09:00.000000000                   1
```

Use a timestamp in Chicago UTC time, a runtime value from the table column `ts`, as a filter on the `test_timezone` table.

SQL

```
SELECT * FROM test_timezone
    WHERE CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts::timestamp, 'America/Chicago')='2022-11
```

*Output*

Text

```
ts                                                  b
-----------------------------------------------------
2022-11-06 08:09:00.000000000                       1
```

## Convert a Timestamp in the Grouping Part of the Query

Group the query results by a timestamp converted to UTC time in Chicago.

SQL

```
SELECT CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts::timestamp, 'America/Chicago')
    FROM test_timezone GROUP BY CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts::timestamp, 'Amer
```

*Output*

Text

```
CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts, ('America/Chicago'))
-------------------------------------------------------
2022-11-09 14:09:00.000000000
2022-11-06 14:09:00.000000000
2022-11-04 14:09:00.000000000
2022-11-05 14:09:00.000000000
```

Using a grouping, omit the `2022-11-05 14:09:00` timestamp using the `HAVING` clause.

SQL

```
SELECT CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts::timestamp, 'America/Chicago')
    FROM test_timezone GROUP BY CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts::timestamp, 'Amer
    HAVING CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts::timestamp, 'America/Chicago') != '202
```

*Output*

Text

```
CONVERT_LOCAL_TIMESTAMP_TO_UTC(ts, ('America/Chicago'))
-------------------------------------------------------
2022-11-09 14:09:00.000000000
2022-11-06 14:09:00.000000000
2022-11-04 14:09:00.000000000
```

# Tuple Functions and Operators

Reference for Ocient SQL tuple functions and operators for constructing, accessing, comparing, and operating on composite tuple values in analytic queries.

## Tuple Functions

| Function | Syntax | Purpose |
|---|---|---|
| Constructor | tuple<<TYPE1,TYPE2, ..., TYPEn>>(e1, e2, ..., en) | Construct a tuple given elements. NULL is also supported as an element. |
| Implicit Constructor | tuple(e1, e2, ..., en) | Construct a tuple with the specified elements. Types of the tuple are inferred from the inner elements. |
| ROW Constructor | ROW(e1, e2, ..., en) | Alias for `tuple(e1, e2, …, en)`. Constructs a tuple with element types inferred from the inner elements. |
| convert tuple to string | char(tuple) | Converts a tuple to its string representation. |
| convert string to tuple | string_to_tuple(str, format) | Converts the string representation of a tuple (e.g., 'tuple<<INT,BIGINT,CHAR>>(1,2,NULL)') into a tuple. |
| tuple casting | cast_to_tuple(tuple, format) | Converts a tuple into another tuple of a different type (e.g., cast_to_tuple(tuple<<int,int>>(1,2), 'TUPLE(BIGINT,DOUBLE)')). |

## Tuple Function Examples

| Function | SQL statement | Result |
|---|---|---|
| type constructor | tuple<<INT,BIGINT>>(1,2) | tuple holding INT(1) and BIGINT(2) |
| type constructor for array of tuples | tuple<<INT,BIGINT>>[](tuple<<INT,BIGINT>>(1,2), tuple<<INT,BIGINT>>(3,4)) | array holding 2 tuples: [(1,2), (1,2)] |
| ROW constructor | ROW(1, 2) | tuple holding INT(1) and INT(2) (equivalent to `tuple(1, 2)`) |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

| Function | SQL statement | Result |
|---|---|---|
| char(<tuple value>) | char(tuple<<INT,BIGINT>>(1,2)) | ‘tuple<<INT,BIGINT>>(1,2)‘ |
| string_to_array | string_to_array(‘tuple<<INT,BIGINT>>[tuple<<INT,BIGINT>>(1,2)]’,‘ARRAY(TUPLE(INT,BIGINT))‘) | tuple<<INT,BIGINT>>[tuple<<INT,BIGINT>>(1,2)] |

# Tuple Operators

| Operator | Syntax | Description |
|---|---|---|
| access operator | tuple[element_index] | Returns the element stored in the specified index position. The index starts at `1`. Access out of bounds returns a NULL. |
| slice operator | tuple[left_index:right_index] | Returns the subtuple ranging from left_index to right_index inclusive. The index starts at `1`. |

## About the Tuple Slice Operator

- Each index starts at `1`.
- If the tuple is NULL or either index value is NULL, the result of the slicing is NULL.
- If you omit the left index, it is equivalent to using `1`. If you omit the right index, it is equivalent to `len(tuple)`. If you omit both, it returns the full tuple. `tuple<<int,int,int>>(1, 2, 3)[:]` is equivalent to `tuple<<int,int,int>>(1, 2, 3)`.
- Values below zero for the left index convert to `1`, and values beyond the tuple length for the right index convert to `len(tuple)`. `tupleVal[-1:4]` is equivalent to `tupleVal[1:4]`, and `tuple<<int,int,int>>(1, 2, 3)[1:6]` is equivalent to `tuple<<int,int,int>>(1, 2, 3)[1:3]`.
- Ranges completely out of tuple bounds throw an invalid argument error, e.g., `tuple<<int,int>>(1,2)[4:5]`.
- Sequential slices slice each dimension of tuples. `tuple<<tuple<<int,int,int>>,tuple<<int,int,int>>>>(tuple<<int,int,int>>(1, 2, 3), tuple<<int,int,int>>(4, 5, 6))[1:1][2:3]` = `tuple<<tuple<<int,int>>>>(tuple<<int,int>>(2, 3))`
- More than N sequential slices of an N-dimensional tuple, for example, three sequential slices on a two-dimensional tuple throw an error. `tuple<<int>>(1)[:][:]`

© 2026 Ocient, Inc

- You cannot combine slicing with the access operator. If you attempt such a combination, any access operator `[n]` converts to `[:n]`. `tupleVal[4][1:6]` = `tupleVal[:4][1:6]`.
- Slicing with non-constant indexes throws an error.
- Slicing a tuple of arrays such as `tuple<<int[],double[]>>(int[1,2,3],double[4,5,6])[1:1][2:3]` slices `[1:1]` on the tuple and `[2:3]` on the resulting inner arrays, resulting in `tuple<<int[]>>(int[2,3])`.
- Slicing a tuple with a mix of containers and primitives such as `tuple<<int,int[]>>(1,int[1,2,3])` throws an error if, at any given depth, the slice is not valid for one or more elements. Slicing the tuple with `[:][2:3]` fails because you cannot slice an integer, and the resultant tuple from `[:]` includes an integer. However, slicing with `[2:2][2:3]` returns `tuple<<int[]>>(int[2,3])` because the tuple resulting from the `[2:2]` slice contains only elements that the next slice range can slice.

### Operator Examples

| Operator | SQL Predicate | Result |
|---|---|---|
| access operator | tuple<<CHAR,BIGINT>>('SQL',2)[1] | 'SQL' |
| access operator | tuple<<CHAR,BIGINT>>('SQL',2)[2] | NULL |
| slice operator | tuple<<CHAR,BIGINT,BIGINT>>('SQL',1,2)[1:2] | tuple<<CHAR,BIGINT>>('SQL',1) |

# Window Aggregate Functions

Reference for Ocient SQL window aggregate functions that compute running sums, moving averages, ranks, and other windowed calculations over partitioned data.

Window functions operate on a set of rows and return a single value for each row from the underlying query. Like aggregate functions, window functions operate on a set of rows, but they do not reduce the number of rows returned by the query.

Unlike regular aggregate functions, window functions do not group rows into a single output row. Instead, the rows retain their separate identities, and the window function produces aggregate calculations that access more than just the current row in the query result.

The term window describes the set of rows on which the window function operates. A window function returns a value from the rows in a window.

The database uses the `ORDER BY` and `PARTITION BY` clauses to define the scope of the window.

### Syntax

Window Aggregate functions follow this syntax with `window_function` representing any of the functions listed in **Supported Window Aggregate Functions**.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
window_function( arg1, arg2 [,...] [ IGNORE NULLS ] )
   OVER (
      [ PARTITION BY part_list ]
      [ ORDER BY order_list [ ASC | DESC ] [ NULLS FIRST | NULLS LAST ] ]
      [ <ROWS_or_RANGE_clause> ] )

<ROWS_or_RANGE_clause> ::=
{ ROWS | RANGE }
   { <window_frame_preceding>
   | BETWEEN { <window_frame_preceding> | <window_frame_following> }
   AND { <window_frame_preceding> | <window_frame_following> }
     }

<window_frame_preceding> ::=
{ UNBOUNDED PRECEDING | row_integer PRECEDING | CURRENT ROW }

<window_frame_following> ::=
{ UNBOUNDED FOLLOWING | row_integer FOLLOWING | CURRENT ROW }
```

| Argument | Data Type | Description |
|---|---|---|
| `arg1, arg2 [,...]` | String | The arguments of the window function. The arguments depend on the type of window function. |

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | String | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | String | Specifies the column by which the rows are ordered. |
| `row_integer` | Numeric | An integer representing the number of rows to operate from the current row. |

## Window Aggregate Keywords

Window aggregate functions use these clauses and keywords to designate the parameters for the query and output.

## PARTITION BY

This clause defines a set of rows within a result set. `PARTITION BY` operates similarly to a **GROUP BY** clause, except it does not reduce the number of rows in the result set.

## ORDER BY

Sorts the result set in ascending or descending order based on one or more specified columns.

An `ORDER BY` clause must be included on all window functions to ensure your query results are deterministic. Some window functions require an `ORDER BY` clause. See the syntax for each function for specifics. For details, see **ORDER BY**.

## ASC or DESC

Specifies whether the values in the specified column should be sorted in `ASC` ascending or `DESC` descending order. `ASC` is the default sort order.

## NULLS FIRST, NULLS LAST, or IGNORE NULLS

Specifies if the database sorts NULL rows first `NULLS FIRST`, last `NULLS LAST`, or whether the database ignores NULLs `IGNORE NULLS`. The default is `NULLS LAST`.

## ROWS or RANGE

Limit the rows within the partition by specifying start and end points within the partition. Specify a range of rows with respect to the current row by logical association using `RANGE` or physical association using `ROWS`.

The `RANGE` clause logically limits the rows within a partition by specifying a range of values with respect to the value in the current row. The system defines preceding or following rows based on the ordering in the `ORDER BY` clause. If you do not specify this clause, the default is ascending order.

The `ROWS` clause limits the rows within a partition by specifying a fixed number of rows preceding or following the current row.

Specifying a window frame by the `RANGE` keyword with the current row `CURRENT ROW` keyword includes all rows with the same values as the current row in the `ORDER BY` clause.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

`ROWS` and `RANGE` clauses can include these options.

| Keyword Clause | Description |
|---|---|
| `UNBOUNDED PRECEDING` | Specifies that the window starts at the first row of the partition. This clause specifies a window starting point only. |
| `UNBOUNDED FOLLOWING` | Specifies that the window ends at the last row of the partition. This clause specifies a window endpoint only.<br>For example:<br>`RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING`<br>This window frame starts with the current row and ends with the last row of the partition. |
| `row_integer PRECEDING` | The `row_integer` value specifies the number of rows or values to precede the current row.<br>You cannot use the `PRECEDING` keyword in a `RANGE` clause. |
| `row_integer FOLLOWING` | The `row_integer` value specifies the number of rows or values to follow the current row.<br>When you specify the `FOLLOWING` keyword as the window starting point, the endpoint must also use a `FOLLOWING` clause with a row value.<br>For example:<br>`ROWS BETWEEN 2 FOLLOWING AND 10 FOLLOWING`<br>This window frame starts with the second row following the current row and ends with the tenth row following the current row.<br>You cannot use the `FOLLOWING` keyword in a `RANGE` clause. |
| `CURRENT ROW` | When you specify the `CURRENT ROW` keyword in a `ROWS` clause, the window frame starts or ends at the current row.<br>When you specify this keyword in a `RANGE` clause, the window frame includes all rows with equal values.<br>For example:<br>`ROWS BETWEEN 2 PRECEDING AND CURRENT ROW`<br>This clause means that the window function operates on a frame of three rows in size, where the first two rows precede the current row (inclusive).<br>You can specify the current row as either a starting or an end point. |

## Use Aggregate Functions as Window Functions

You can use any standard aggregate function that accepts an `OVER` clause as a window function. When you add an `OVER` clause to an aggregate function, the function computes the aggregate value for the window frame for each row without collapsing rows.

The following aggregate functions support the `OVER` clause:

- `AVG`

- `COUNT`
- `KURTOSIS`
- `KURTOSISP`
- `MAX`
- `MIN`
- `PRODUCT`
- `SKEW`
- `SKEWP`
- `STDEV`
- `STDEVP`
- `SUM`
- `VARIANCE`
- `VARIANCEP`

This example applies `SUM`, `AVG`, and `COUNT` as window functions to calculate a running salary total, a department average, and a department row count for each employee without collapsing rows.

SQL

```
SELECT
    department,
    employee_name,
    salary,
    SUM(salary) OVER (PARTITION BY department ORDER BY hire_date) AS running_total,
    AVG(salary) OVER (PARTITION BY department) AS dept_avg,
    COUNT(*) OVER (PARTITION BY department) AS dept_count
FROM employees;
```

Output

| department | employee_name | salary | running_total | dept_avg |
|---|---|---|---|---|
| Engineering | Alice | 120000 | 120000 | 130000.0 |
| Engineering | Bob | 150000 | 270000 | 130000.0 |

| department | employee_name | salary | running_total | dept_avg |
|---|---|---|---|---|
| Engineering | Carol | 120000 | 390000 | 130000.0 |
| Marketing | Dan | 90000 | 90000 | 95000.0 |
| Marketing | Eve | 100000 | 190000 | 95000.0 |

The `ANY_VALUE` aggregate function does not support window aggregation.

## Named Windows

You can define reusable window specifications using the `WINDOW` clause in a `SELECT` SQL statement. Named windows reduce repetition when multiple window functions share the same partitioning, ordering, or framing. For full syntax details, see **WINDOW**.

This example defines a named window `w` that partitions rows by department and orders them by salary in descending order, then reuses `w` across three window functions to calculate a row number, a running sum, and a rank for each employee.

SQL

```
SELECT
    department,
    employee_name,
    salary,
    ROW_NUMBER() OVER w AS row_num,
    SUM(salary) OVER w AS running_sum,
    RANK() OVER w AS rnk
FROM employees
WINDOW w AS (PARTITION BY department ORDER BY salary DESC)
ORDER BY department, salary DESC;
```

Output

| department | employee_name | salary | row_num | running_sum |
|---|---|---|---|---|
| Engineering | Bob | 150000 | 1 | 150000 |
| Engineering | Alice | 120000 | 2 | 270000 |

| department | employee_name | salary | row_num | running_sum |
|---|---|---|---|---|
| Engineering | Carol | 110000 | 3 | 380000 |
| Marketing | Eve | 100000 | 1 | 100000 |
| Marketing | Dan | 90000 | 2 | 190000 |

Named windows support chaining, so one named window can reference another, and parenthesized references, which merge additional clauses into a base window. Each named window applies only within the `SELECT` statement that defines it.

## Supported Window Aggregate Functions

These functions are supported for window frames. Some examples use the `sys.dummy` virtual table to populate data. For details, see **Generate Tables Using sys.dummy**.

> You cannot use the `DISTINCT` keyword with window aggregation functions.

### CUME_DIST

Returns a positive value less than one that represents a percentage of values that are less than or equal to the current value in the group.

#### Syntax

SQL

```
CUME_DIST ()
   OVER ( [ PARTITION BY part_list ] ORDER BY order_list )
```

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

#### Example

This example shows the cumulative distribution values for a table with generated numbers from one to 10.

SQL

```
SELECT x, CUME_DIST()
    OVER (ORDER BY x) AS d
    FROM (SELECT c1 AS x FROM sys.dummy10);
```

Output

Text

```
| "x" | "d" |
|-----|-----|
|   1 | 0.1 |
|   2 | 0.2 |
|   3 | 0.3 |
|   4 | 0.4 |
|   5 | 0.5 |
|   6 | 0.6 |
|   7 | 0.7 |
|   8 | 0.8 |
|   9 | 0.9 |
|  10 | 1.0 |
```

## DELTA

Computes the finite difference between successive values of expression under the specified ordering. This is a backward difference, meaning the delta value for a specified row is the difference between the value of that row and the previous row.

The function requires two rows of input data to calculate a first-degree difference, three rows of input data to calculate a second-degree difference, and so on.

However, rather than returning NULL for the first few rows, the function returns the correct values, such that using DELTA of degree `n` followed by DELTA of degree `-n` cancel each other out to return the initial result (other than floating point error accumulation). In general, using this window function over larger result sets with large degrees worsens floating-point error accumulation.

Integer degree values in the range `[-3, 3]` are generally stable up to approximately five million rows. Fractional degree values in the range `[-3, 3]` are generally stable up to approximately one million rows. The stable degree range is wider over smaller result sets and narrower over larger result sets. For example, fractional and integer degrees are stable over the range `[-4, 4]` up to approximately 80,000 rows.

> ⚠ The function treats any NULL values in the input data as zero, which might cause unexpected results. Filter out NULL values before you use the window function.

### Syntax

SQL

```
DELTA ( expression [, degree ])
   OVER (
      [ PARTITION BY part_list ]
      ORDER BY order_list )
```

| Argument | Data Type | Description |
|---|---|---|
| `expression` | Numeric | The column or expression to use for the DELTA calculation. |
| `degree` | Numeric | Optional.<br>If `degree` is set to a positive integer greater than 1, the window function calculates the higher-order finite difference without using nested `DELTA` calls.<br>If negative, the calculation is an anti-difference (i.e., discrete integration).<br>You can specify fractional values, either positive or negative, and these values mean fractional differences or sums.<br>The default is `1`. |

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

### Examples

### Calculate Difference Values Using Basic Numbers

This example shows the delta values for a table with generated numbers from one to 10.

SQL

```
SELECT y, DELTA(y, 1)
    OVER (ORDER BY y) AS d
    FROM (SELECT DOUBLE(c1 * c1) AS y FROM sys.dummy10);
```

Output

Text

```
| "y" | "d" |
|-----|-----|
| 1   | 1   |
| 4   | 3   |
| 9   | 5   |
| 16  | 7   |
| 25  | 9   |
| 36  | 11  |
| 49  | 13  |
| 64  | 15  |
| 81  | 17  |
| 100 | 19  |
```

### Calculate Difference Values Using Partitioned Sales Data

This example uses the `DELTA` function with a table of regional sales data to find the difference in sales by region and year.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT
    region,
    year,
    sales_amount,
    DELTA(sales_amount) OVER (PARTITION BY region ORDER BY year) AS sales_delta
FROM
    regional_sales
ORDER BY
    region,
    year;
```

Output

Text

```
| "region" | "year" | "sales_amount" | "sales_delta" |
|----------|--------|----------------|---------------|
| North    |   2018 |          12000 |         12000 |
| North    |   2019 |          15000 |          3000 |
| North    |   2020 |          17000 |          2000 |
| North    |   2021 |          16000 |         -1000 |
| North    |   2022 |          18000 |          2000 |
| South    |   2018 |          10000 |         10000 |
| South    |   2019 |          14000 |          4000 |
| South    |   2020 |          15000 |          1000 |
| South    |   2021 |          17000 |          2000 |
| South    |   2022 |          16000 |         -1000 |
```

## DENSE_RANK

Assigns a rank to each row in the result set with equal values having the same number. There are no gaps between ranks.

### Syntax

SQL

```
DENSE_RANK ()
   OVER ( [ PARTITION BY part_list ] ORDER BY order_list )
```

© 2026 Ocient, Inc

| Parameter | Data Type | Description |
| --- | --- | --- |
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

### Example

This example generates the rank for a series of ten random numbers. Use the **RAND** function to generate the random numbers.

SQL

```
WITH RandomNumbers AS (
    SELECT RAND() AS num
    FROM sys.dummy10
)
SELECT num, DENSE_RANK()
    OVER (ORDER BY num) AS n
    FROM RandomNumbers;
```

Output

Text

```
|         num          |  n  |
| -------------------- | --- |
| 0.021744504292815926 | 1   |
| 0.11531389663905277  | 2   |
| 0.17818297230968436  | 3   |
| 0.3009914646699445   | 4   |
| 0.366713904443239    | 5   |
| 0.7801256114813641   | 6   |
| 0.8735727062571587   | 7   |
| 0.8969752860565523   | 8   |
| 0.9679736914744647   | 9   |
| 0.9910291449541664   | 10  |
```

## DERIVATIVE

The function calculates the difference between successive values of two numeric expressions, representing a backward difference (e.g., the difference between the current and previous row). It can be considered as computing the derivative of one expression with respect to another.

The function must use an `ORDER BY` clause, and it cannot use a `PARTITION BY` clause.

`DERIVATIVE` requires two arguments, `expression` and `expression2`, which must be included in the `ORDER BY` clause.

The function computes the difference in `expression` values between consecutive rows and divides this by the difference in `expression2` values over the same rows. If `expression` represents some measured value and `expression2` is time, the result is the rate of change (derivative) of the value with respect to time.

The function can compute higher-degree derivatives (second, third, etc.). To calculate the `nth`-degree derivative, it uses a backward difference formula that compares the current row to the previous `n` rows.

For example:

- A second-degree derivative requires three rows of data: the current row, the previous row, and the one before the previous row.
- A third-degree derivative would require four rows, and so on.

Unlike some functions that return NULL for rows that lack sufficient preceding data, the `DERIVATIVE` function is designed to return correct values even for initial rows. This behavior ensures that if you apply a derivative of degree `n` followed by its inverse (derivative of degree `-n`), you recover the original values with minimal error (except for floating point inaccuracies).

In general, using this function over larger result sets with larger degrees worsens the floating-point error. Integer degree values in the range of three are generally stable up to approximately five million rows. Fractional degree values in the range of three are generally stable up to approximately one million rows. The stable degree range is wider over smaller result sets and narrower over larger result sets. For example, fractional and integer degrees are stable over the range `[-4, 4]` up to approximately 80,000 rows.

⚠ For higher-order calls, the sample points for `expression` must be equally spaced, or the function might return incorrect results. In other words, the DELTA executions between consecutive `expression2` values must always be the same. If this is not true, use some form of interpolation to create an evenly-spaced series of samples before you use the window function.

⚠ The function treats any NULL values in the input data for either `expression` or `expression2` arguments as zero, which might cause unexpected results. Filter out NULL values before you use the window function.

## Syntax

SQL

```
DERIVATIVE ( expression [, degree ] )
   OVER ( ORDER BY expression2 )
```

| Argument | Data Type | Description |
|---|---|---|
| `expression` | Numeric | The column or expression to use for the `DERIVATIVE` calculation compared to `expression2`. |
| `expression2` | Numeric | The column or expression to use for the `DERIVATIVE` calculation compared to `expression`. |
| `degree` | Numeric | Optional.<br>If you set `degree` to a positive integer greater than one, the window function calculates the higher-order difference quotients (discrete derivatives) without using nested `DERIVATIVE` executions.<br>If the `degree` argument is a negative integer, the calculation is a discrete anti-differentiation or integration.<br>The default value is `1`. |

## Examples

### Calculate the Derivative Using Basic Numbers

This example shows the derivative values for a basic table with values `x` and `y`.

SQL

```
SELECT x, y, DERIVATIVE(y, 1)
    OVER (ORDER BY x) AS d
    FROM (SELECT DOUBLE(2 * x + 1) AS y, x
        FROM (SELECT c1/2.0 AS x FROM sys.dummy10));
```

Output

Text

```
| "x" | "y"  | "d" |
|-----|------|-----|
| 0.5 |  2.0 | 4.0 |
| 1.0 |  3.0 | 2.0 |
| 1.5 |  4.0 | 2.0 |
| 2.0 |  5.0 | 2.0 |
| 2.5 |  6.0 | 2.0 |
| 3.0 |  7.0 | 2.0 |
| 3.5 |  8.0 | 2.0 |
| 4.0 |  9.0 | 2.0 |
| 4.5 | 10.0 | 2.0 |
| 5.0 | 11.0 | 2.0 |
```

### Calculate the Antiderivative Using a Negative Degree

This example uses a negative degree to produce an antiderivative.

SQL

```
SELECT x, y, DERIVATIVE(y, -1)
    OVER (ORDER BY x) AS d
    FROM (SELECT DOUBLE(2 * x + 1) AS y, x
        FROM (SELECT c1/2.0 AS x FROM sys.dummy10));
```

Output

Text

```
| "x" | "y"  | "d"  |
|-----|------|------|
| 0.5 |  2.0 |  1.0 |
| 1.0 |  3.0 |  2.5 |
| 1.5 |  4.0 |  4.5 |
| 2.0 |  5.0 |  7.0 |
| 2.5 |  6.0 | 10.0 |
| 3.0 |  7.0 | 13.5 |
| 3.5 |  8.0 | 17.5 |
| 4.0 |  9.0 | 22.0 |
| 4.5 | 10.0 | 27.0 |
| 5.0 | 11.0 | 32.5 |
```

## FIRST_VALUE

Returns the first value in the ordered result set.

### Syntax

SQL

```
FIRST_VALUE ( expression )
    OVER ( [ PARTITION BY part_list ] [ ORDER BY order_list ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `expression` | Any | The column or expression value to use for the `FIRST_VALUE` calculation. |

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

### Example

This example uses a table with generated numbers from one to 10. Of this group, the function determines the first value from the ordering.

SQL

```
SELECT y, FIRST_VALUE(y)
    OVER (ORDER BY y) AS first_value
    FROM (SELECT c1 AS y FROM sys.dummy10);
```

Output

Text

```
| "y" | "first_value" |
|-----|---------------|
|   1 |             1 |
|   2 |             1 |
|   3 |             1 |
|   4 |             1 |
|   5 |             1 |
|   6 |             1 |
|   7 |             1 |
|   8 |             1 |
|   9 |             1 |
|  10 |             1 |
```

## LAG

Returns a row backward from the current row (one row back unless you specify a different number value).

For marking repeated LAG calls on one or more columns, see **Data Preparation**.

### Syntax

SQL

```
LAG (value_expr [, offset ])
    OVER ( [ PARTITION BY part_list ] [ ORDER BY order_list ] )
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `value_expr` | Any | The column or expression to use for the `LAG` calculation. |
| `offset` | Numeric | Optional.<br>This number determines how many rows back from the current row to return a value.<br>The default value is `1`. |

| Parameter | Data Type | Description |
| --- | --- | --- |
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

## Examples

### Calculate Lag Using Basic Numbers

This example uses a table with generated numbers from one to 10. Of this group, the `LAG` function returns the last value for the specified column `y`.

SQL

```
SELECT y, LAG(y)
    OVER (ORDER BY y) AS wf
    FROM (SELECT c1 AS y FROM sys.dummy10);
```

Output

Text

```
| "y" | "wf" |
|-----|------|
|   1 |      |
|   2 |    1 |
|   3 |    2 |
|   4 |    3 |
|   5 |    4 |
|   6 |    5 |
|   7 |    6 |
|   8 |    7 |
|   9 |    8 |
|  10 |    9 |
```

### Calculate Lag Using an Offset

In this example, the offset value `5` changes the number of rows back from the current row from which to return a value.

SQL

```sql
SELECT y, LAG(y, 5)
    OVER (ORDER BY y) AS wf
    FROM (SELECT c1 AS y FROM sys.dummy10);
```

Output

© 2026 Ocient, Inc

Text

```
| "y" | "wf" |
|-----|------|
|   1 |      |
|   2 |      |
|   3 |      |
|   4 |      |
|   5 |      |
|   6 |    1 |
|   7 |    2 |
|   8 |    3 |
|   9 |    4 |
|  10 |    5 |
```

## LAST_VALUE

Returns the last value in the ordered result set.

### Syntax

SQL

```
LAST_VALUE ( expression )
    OVER ( [ PARTITION BY part_list ] [ ORDER BY order_list ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `expression` | Any | The column or expression value to use for the `LAST_VALUE` calculation. |

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

### Example

This example uses a table with generated numbers from one to 10. Of this group, the function determines the last value from the ordering.

SQL

```
SELECT y, LAST_VALUE(y)
    OVER (ORDER BY y) AS last_value
    FROM (SELECT c1 AS y FROM sys.dummy10);
```

Output

Text

```
| "y" | "last_value" |
|-----|--------------|
|   1 |            1 |
|   2 |            2 |
|   3 |            3 |
|   4 |            4 |
|   5 |            5 |
|   6 |            6 |
|   7 |            7 |
|   8 |            8 |
|   9 |            9 |
|  10 |           10 |
```

## LEAD

Returns a row forward from the current row (one row forward unless you specify a different number value).

### Syntax

SQL

```
LEAD (value_expr [, offset ])
    OVER ( [ PARTITION BY part_list ] [ ORDER BY order_list ] )
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `value_expr` | Any | The value to use for the `LEAD` calculation. |
| `offset` | Numeric | Optional.<br>This number determines how many rows forward from the current row to return a value.<br>The default value is `1`. |

| Parameter | Data Type | Description |
| --- | --- | --- |
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

## Examples

### Calculate the Lead Value Using Basic Numbers

This example uses a table with generated numbers from one to 10. Of this group, the `LEAD` function returns the last value for the specified column `y`.

SQL

```
SELECT y, LEAD(y)
    OVER (ORDER BY y) AS lead_value
    FROM (SELECT c1 AS y FROM sys.dummy10);
```

Output

Text

```
| "y" | "lead_value" |
|-----|--------------|
|   1 |            2 |
|   2 |            3 |
|   3 |            4 |
|   4 |            5 |
|   5 |            6 |
|   6 |            7 |
|   7 |            8 |
|   8 |            9 |
|   9 |           10 |
|  10 |              |
```

### Calculate the Lead Value Using an Offset

In this example, using a table of generated numbers with values from one to 10, specify the offset value `5` in the `LEAD` function to change the number of rows forward from the current row to return a value.

SQL

```sql
SELECT y, LEAD(y, 5)
    OVER (ORDER BY y) AS lead_value
    FROM (SELECT c1 AS y FROM sys.dummy10);
```

Output

Text

```
| "y" | "lead_value" |
|-----|--------------|
|   1 |            6 |
|   2 |            7 |
|   3 |            8 |
|   4 |            9 |
|   5 |           10 |
|   6 |              |
|   7 |              |
|   8 |              |
|   9 |              |
|  10 |              |
```

## NTH_VALUE

Returns the `n`-th value in the ordered result set.

### Syntax

SQL

```
NTH_VALUE (expr, offset)
    OVER ( [ PARTITION BY part_list ] [ ORDER BY order_list ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `expr` | Any | The column or expression from which to retrieve a value. |
| `offset` | Numeric | A positive integer that indicates the row number, starting from the first row in the window. This integer must be positive. |

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

## Examples

### Calculate the Fifth Value Using Bounded Rows

This example uses a table with generated numbers from one to 10. Of this group, the `NTH_VALUE` function returns the fifth value for the specified column `y`.

For the first four rows, the window contains fewer than five rows, so the function returns NULL because the fifth value is not yet available.

SQL

```
SELECT y, NTH_VALUE(y, 5)
    OVER (ORDER BY y) AS nth
    FROM (SELECT c1 AS y FROM sys.dummy10);
```

Output

Text

```
| "y" | "nth" |
|-----|-------|
|   1 |       |
|   2 |       |
|   3 |       |
|   4 |       |
|   5 |     5 |
|   6 |     5 |
|   7 |     5 |
|   8 |     5 |
|   9 |     5 |
|  10 |     5 |
```

### Calculate the Fifth Value Using Unbounded Rows

To include future rows in the window frame, you can modify the window frame as shown in this example.

© 2026 Ocient, Inc
Ocient Proprietary and Confidential

SQL

```
SELECT y, NTH_VALUE(y, 5)
    OVER ( ORDER BY y ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS
FROM
    (SELECT c1 AS y FROM sys.dummy10);
```

Output

Text

```
| "y" | "nth" |
|-----|-------|
|   1 |     5 |
|   2 |     5 |
|   3 |     5 |
|   4 |     5 |
|   5 |     5 |
|   6 |     5 |
|   7 |     5 |
|   8 |     5 |
|   9 |     5 |
|  10 |     5 |
```

## PERCENTILE

Returns the value corresponding to the specified percentile ($0 \leq$ `n` $\leq 1$) within the group.

The set of values is treated as a continuous distribution, so it is possible that the computed value cannot appear in the result set.

### Syntax

SQL

```
PERCENTILE (expr, percentile)
    OVER ( [ PARTITION BY part_list ] [ ORDER BY order_list ] )
```

| Argument | Data Type | Description |
| --- | --- | --- |
| `expr` | Any | The column or expression to use for the `PERCENTILE` calculation. |
| `percentile` | Float | A percentile (0 ≤ `n` ≤ 1) to determine the value to return by its position within the ordering of `expr`. |

| Parameter | Data Type | Description |
| --- | --- | --- |
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

### Example

This example finds the value at approximately 90 percent of the range of the expression values. For the source data, use a table of generated numbers from one to 10.

The value returns `9.1` because the window column starts at `1`. It would be `9` if the column started at `0`.

SQL

```
SELECT y, PERCENTILE(y, 0.9)
    OVER (ORDER BY y) AS percentile_value
    FROM (SELECT c1 AS y FROM sys.dummy10);
```

Output

Text

```
| "y" | "percentile_value" |
|-----|--------------------|
|   1 |                9.1 |
|   2 |                9.1 |
|   3 |                9.1 |
|   4 |                9.1 |
|   5 |                9.1 |
|   6 |                9.1 |
|   7 |                9.1 |
|   8 |                9.1 |
|   9 |                9.1 |
|  10 |                9.1 |
```

## PERCENT_RANK

Returns a percentage value for each row representing the percentage of values less than the current group, excluding the highest value. The highest value in a group is always 1.

### Syntax

SQL

```
PERCENT_RANK ()
    OVER ( [ PARTITION BY part_list ] ORDER BY order_list )
```

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

### Example

This example generates the percent rank of the table with ten generated numbers from one to 10.

SQL

```
SELECT y, PERCENT_RANK()
    OVER (ORDER BY y) AS percent_rank
    FROM (SELECT c1 AS y FROM sys.dummy10);
```

Output

Text

```
| "y" |   "percent_rank"   |
|-----|--------------------|
|   1 |                0.0 |
|   2 | 0.1111111111111111 |
|   3 | 0.2222222222222222 |
|   4 | 0.3333333333333333 |
|   5 | 0.4444444444444444 |
|   6 | 0.5555555555555556 |
|   7 | 0.6666666666666666 |
|   8 | 0.7777777777777778 |
|   9 | 0.8888888888888888 |
|  10 |                1.0 |
```

## RANK

Assigns a rank number to each row in the result set with equal values having the same number. There can be gaps between ranks. Results are similar to the ranking used in sporting events.

### Syntax

SQL

```
RANK ()
    OVER ( [ PARTITION BY part_list ] ORDER BY order_list )
```

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |

| Parameter | Data Type | Description |
| --- | --- | --- |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

### Example

This example ranks a series of ten random numbers. Use the **RAND** function to generate the random numbers.

SQL

```
WITH RandomNumbers AS (
    SELECT RAND() AS num
    FROM sys.dummy10
)
SELECT num, RANK() OVER (ORDER BY num) AS n
FROM RandomNumbers;
```

Output

Text

```
|  num                |  n  |
| ------------------- | --- |
| 0.0003210869634629  | 1   |
| 0.03250125317575761 | 2   |
| 0.09413438896602266 | 3   |
| 0.130728439355569   | 4   |
| 0.376078282337459   | 5   |
| 0.5049826734614208  | 6   |

```

## RATIO_TO_REPORT

Computes the ratio of a value to the sum of the set of values. For example, the `RATIO_TO_REPORT` function calculates the ratio of the salary of an employee relative to the total salaries in the department where the employee belongs.

## Syntax

```
SQL

RATIO_TO_REPORT ( ratio_expression )
    OVER ( [ PARTITION BY part_list ] [ ORDER BY order_list ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `ratio_expression` | Numeric | A column or expression to calculate the ratio for each row compared to the total. |

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

## Example

This example shows a ratio of each salary of an individual employee to the total salaries.

```
SQL

SELECT name, salaries, RATIO_TO_REPORT(salaries)
    OVER (ORDER BY salaries) AS ratio
    FROM salaries;
```

Output

Text

```
|      name       |  salaries |        ratio        |
|-----------------|-----------|---------------------|
| Vasquez, Gustav |   70000.0 | 0.08484848484848485 |
| Ho, Chen        |   75000.0 | 0.09090909090909091 |
| Kiwi, Marie     |  110000.0 | 0.13333333333333333 |
| Smith, Roberts  |  140000.0 |  0.1696969696969697 |
| Porter, Polly   |  180000.0 | 0.21818181818181817 |
| Svenson, Olaf   |  250000.0 | 0.30303030303030304 |
```

## ROW_NUMBER

Assigns a unique number to each row in the result set.

### Syntax

SQL

```
ROW_NUMBER ()
    OVER ( [ PARTITION BY part_list ] [ ORDER BY order_list ] )
```

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

### Examples

#### Determine the Unique Number of Each Row in a Table

This example assigns a row number to a basic table of fruit prices based on the price order.

SQL

```sql
SELECT fruit, price, ROW_NUMBER()
OVER (ORDER BY price) AS row_no
    FROM fruits;
```

Output

Text

```
|  "fruit"   | "price" |"row_no"|
|------------|---------|--------|
| banana     |     0.5 |      1 |
| kiwi       |    0.75 |      2 |
| orange     |     1.5 |      3 |
| mango      |    1.75 |      4 |
| apple      |    1.99 |      5 |
| strawberry |    3.99 |      6 |
```

### Determine the Unique Number of Each Row Using a Partitioned Table

This example uses a table of sales data for two regions. The `ROW_NUMBER` function orders the sales team members by their region and sales amounts.

SQL

```sql
SELECT
    salesperson,
    region,
    sales_amount,
    SUM(sales_amount) OVER (PARTITION BY region) AS total_sales_by_region,
    ROW_NUMBER() OVER (PARTITION BY region ORDER BY sales_amount DESC) AS sales_ran
FROM
    sales;
```

Output

Text

```
| "salesperson" | "region" | "sales_amount" | "total_sales_by_region" | "sales_rank
|---------------|----------|----------------|-------------------------|------------
| Eve           | North    |           2500 |                    5000 |
| Bob           | North    |           1500 |                    5000 |
| Alice         | North    |           1000 |                    5000 |
| Dave          | South    |           3000 |                    5000 |
| Carol         | South    |           2000 |                    5000 |
```

## ZSCORE

Calculates the z-score of the sample based on the standard deviation (similar to the **STDDEV** aggregate function).

The standard deviation assumes that the data is a sample of a larger set, meaning it corrects for bias.

If your data set is comprehensive and represents an entire group, use the **ZSCOREP** function instead.

### Syntax

SQL

```
ZSCORE (expr)
    OVER ( [ PARTITION BY part_list ] [ ORDER BY order_list ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `expr` | Numeric | A column or expression to calculate the standard deviation for each row. |

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

### Example

This example calculates the standard deviation in a range of salaries.

SQL

```
SELECT name, salaries, ZSCORE(salaries)
OVER (ORDER BY salaries) AS std_dev
    FROM salaries;
```

Output

Text

```
|      name       | salaries |      std_dev       |
|-----------------|----------|--------------------|
| Vasquez, Gustav |  70000.0 |                    |
| Ho, Chen        |  75000.0 | 0.7071076862849652 |
| Kiwi, Marie     | 110000.0 | 1.1470789011835154 |
| Smith, Roberts  | 140000.0 | 1.2593337909146212 |
| Porter, Polly   | 180000.0 | 1.4100478781464227 |
| Svenson, Olaf   | 250000.0 |  1.634473657490547 |
```

## ZSCOREP

Calculates the z-score of the sample based on the population standard deviation (similar to the **STDEVP** aggregate function).

The population standard deviation assumes that the data contains the entire population, meaning there is no correction for bias. Use it when your data set is comprehensive and represents the entire group (i.e. population) you are analyzing.

If your data set is a sample of a larger set, use the **ZSCORE** function.

### Syntax

SQL

```
ZSCOREP (expr)
    OVER ( [ PARTITION BY part_list ] [ ORDER BY order_list ] )
```

| Argument | Data Type | Description |
|---|---|---|
| `expr` | Numeric | A column or expression to calculate the standard deviation for each row. |

| Parameter | Data Type | Description |
|---|---|---|
| `part_list` | Any | Specifies the column by which the rows are partitioned for the window function. |
| `order_list` | Any | Specifies the column by which the rows are ordered for the window function. |

### Example

This example calculates the population standard deviation in a range of salaries.

SQL

```
SELECT name, salaries, ZSCOREP(salaries)
OVER (ORDER BY salaries) AS std_devp
    FROM salaries;
```

Output

Text

```
|      name       | salaries |      std_devp      |
|-----------------|----------|--------------------|
| Vasquez, Gustav |  70000.0 |                    |
| Ho, Chen        |  75000.0 | 1.0000012800024576 |
| Kiwi, Marie     | 110000.0 | 1.4048790013060097 |
| Smith, Roberts  | 140000.0 | 1.4541534063682966 |
| Porter, Polly   | 180000.0 | 1.5764814535323706 |
| Svenson, Olaf   | 250000.0 | 1.7904761837110903 |
```
